At the time of the Spanish exploration of Cuba, the native population formed two groups totaling 50,000. The Ciboney and Guanahatabey occupied western Cuba. The more numerous Taino, who occupied the rest of the island, were highly developed agriculturalists and a peaceful people, related to the Arawakan peoples of South America who had migrated to the Greater Antilles. Their houses, called *bohíos,* formed villages ranging from single families to communities of 3,000 persons. They had pottery, polished stone implements, and religious spirits called *zemis,* which were represented by idols of wood, stones, and bones. The Taino diet included potatoes, manioc, fruits, and fish.

The **Spanish colonial regime.** Christopher Columbus discovered Cuba for Spain during his first voyage, on Oct. 27, 1492. Diego Velázquez began permanent settlement in 1511, founding Baracoa on the northeastern coast with 300 Spaniards and their African slaves.

Within five years the island had been divided into seven municipal divisions, including Havana, Puerto Príncipe, Santiago de Cuba, and Sancti Spíritus. Each municipality had its own cabildo, or town council, governing its legal, administrative, and commercial affairs. From 1515, elected representatives of each cabildo formed a body that defended local interests before the royal council, especially matters such as the slave trade and the encomienda (a system that granted to conquistadors a certain number of Indians in a specified area from whom tribute could be exacted). A bishopric, subordinate to Santo Domingo, was founded at Baracoa in 1518 but later moved to Santiago de Cuba.

The island's limited gold deposits discouraged early settlement. The colony became a staging ground for the mainland exploration of Yucatán, Florida, and the Gulf Coast. Such expeditions as that of Cortés, which attracted

400 Spaniards and 3,000 Indians, depleted the colonial population. The small number of permanent resident Spanish colonists used the Indians in encomienda. But by 1550 the encomienda was no longer feasible, because the island's Indian population had declined dramatically to about 5,000 because of social dislocation, maltreatment, epidemic diseases, and emigration. Throughout the 17th century, colonial life was made more difficult by the ravages of hurricanes, epidemics, the attacks of rival European countries trying to establish bases in the Caribbean, and pirates. By 1700 peace had returned, and the population had grown to about 50,000. The *flota* system (regularly scheduled fleets between Spain and Spanish America) increased the commercial and strategic importance of Havana, while ranching, smuggling, and tobacco farming occupied the colonists. The administrative costs depended, however, on irregular subsidies from New Spain until 1808.

The 18th century brought intensified agricultural development. The main changes came with the growing dependence on sugarcane cultivation and the importation of African slaves for work on the plantations. In 1740 the Havana Company was formed to stimulate agricultural development by increasing the importation of slaves and regulating the export trade. The company was unsuccessful, selling fewer slaves in 21 years than the British sold during a 10-month occupation of Havana in 1762. Reforms of Charles III of Spain at this time further stimulated the development of the sugar industry.

Between 1763 and 1860 the island's population increased from less than 150,000 to more than 1.3 million. Slaves made the most dramatic growth, increasing from 39,000 in the 1770s to some 400,000 in the 1840s. In the 19th century Cuba imported more than 600,000 Africans, most of them after an Anglo-Spanish agreement to terminate the slave trade in 1820. The Cuban insistence on the slave trade raised considerable diplomatic controversy between Spain and Great Britain between 1817 and 1865.

In 1838–80 the Cuban sugar industry became the most mechanized in the world, utilizing steam-powered mills and narrow-gauge railroads. Expanding *ingenios* (sugar mills) dominated the landscape from Havana to Puerto Príncipe, expelling small farmers and destroying the island's famous large hardwood forests. By 1850 the sugar industry accounted for 83 percent of all exports, and in 1860 Cuba produced nearly one-third of the world's sugar. The sugar revolution propelled a new rich class of slave owners to political prominence. Mexican Indians and Chinese augmented the labour force, and in 1865 the African slave trade ended, although slavery was not abolished until 1886.

The demands of sugar—labourers, capital, machines, technical skills, and markets—strained interracial relations, aggravated political and economic differences between metropolis and colony, and laid the foundation for the break with Spain in 1898. Spanish colonial administration had been corrupt, inefficient, and inflexible. The United States had shown a lively and growing interest in the island, and expeditions by U.S. filibusters won support in the United States, especially in the Southern slave states. After the 1860s the United States tried many times to purchase the island.

Spain's failure to grant political autonomy, while increasing taxes, led to the outbreak of the first war of independence—the Ten Years' War (1868–78)—which led to a military stalemate. The rich sugar producers of western Cuba and the vast majority of the slaves failed to rally to the nationalists, themselves divided over the questions of slavery, complete independence, and annexation to the United States. Spain promised to reform the island's political and economic system at the Convention of Zanjón (1878). Many Cubans, including the nationalist leader Antonio Maceo, however, refused to accept the Spanish conditions.

By 1895 the political and economic crisis had grown more severe. U.S. investment had reached $50 million, and its annual trade with Cuba amounted to about $100 million. Cuban political organizations in exile were coordinated and mobilized by the poet and propagandist José Martí. War broke out again on Feb. 24, 1895.

Pre-Columbian Cuba

Dependence of the economy on sugarcane

The Ten Years' War

Spain deployed more than 200,000 troops. Both sides killed civilians and burned estates and towns. By 1898 commercial activity had come to a standstill. Excited by the "yellow press" and a mysterious explosion aboard the USS *Maine* in Havana's harbour, the United States declared war on Spain on April 25, 1898. In August Spain signed a peace protocol in Washington, ending hostilities.

U.S. occupation, 1899–1901. Cuban independence, granted by the Treaty of Paris (Dec. 10, 1898), began Jan. 1, 1899, under U.S. occupation. The military governor, General John Brooke, tried to exclude Cubans from government. He disbanded the Cuban army and conducted a census before being replaced by General Leonard Wood, a former military governor of Santiago City. Wood sought to mitigate political division and supervised elections that gave Cuba its first elected president, Tomás Estrada Palma.

The military occupation restored normality. The Americans built a number of schools, roads, and bridges; they modernized Havana and deepened its harbour. But Americans were primarily interested in preparing the island for incorporation into the U.S. economic, cultural, and educational systems, and the franchise was designed to eliminate Afro-Cubans from politics. The Platt Amendment (1901) gave the United States the right to oversee Cuba's international commitments, economy, and internal affairs and to establish a naval station at Guantánamo Bay.

<aside>The Platt Amendment</aside>

The Republic of Cuba, 1902–58. A republican administration that began on May 20, 1902, under Tomás Estrada Palma faced difficulties over U.S. influence. Estrada Palma tried to retain power in the 1905 and 1906 elections, which were contested by the Liberals, leading to rebellion and a second U.S. occupation on Sept. 29, 1906. U.S. secretary of war William Howard Taft failed to resolve the dispute, and Estrada Palma resigned. For the United States Charles Magoon administered a provisional government of Cuban civilians under the Cuban flag and constitution. An advisory law commission revised electoral procedures, and on Jan. 28, 1909, Magoon handed over the government to the Liberal president, José Miguel Gómez. Meanwhile, Cuba's economy grew steadily, as sugar prices rose continually until the 1920s.

The Gómez administration (1909–13) set a pattern of graft, corruption, maladministration, fiscal irresponsibility, and social insensitivity—especially toward Afro-Cubans—that characterized Cuban politics until 1959. The Afro-Cubans, led by Evaristo Estenoz and Pedro Ivonet, organized to secure better jobs and more political patronage and to protest a ban of political associations based on colour and race. In 1912 government troops put down large demonstrations in Oriente. The pattern of corruption was followed by Mario García Menocal (1913–21), Alfredo Zayas (1921–25), Gerardo Machado (1925–33), Fulgencio Batista (through puppets 1934–39 and himself 1940–44 and 1952–59), Ramón Grau San Martín (1944–48), and Carlos Prío Socarrás (1948–52). Machado and Batista, who overthrew Machado in 1933 with U.S. support, were the most notorious, holding power through manipulation, troops, and assassins.

The income from sugar was augmented by vigorous tourism based on hotels, casinos, and brothels; Havana became especially attractive during the years of U.S. Prohibition (1919–33). Yet the prosperity of the 1920s, '40s, and '50s enriched only a few Cubans. For the majority, poverty (especially in the countryside) and lack of public services were appalling: with a national per capita income of $353 in 1958—among the highest in Latin America—unemployment and underemployment were rife, and the average rural worker earned $91 per year. Foreign interests controlled the economy, owning about 75 percent of the arable land, 90 percent of the essential services, and 40 percent of the sugar production. Nevertheless, there was no widespread discontent on Jan. 1, 1959, when Fidel Castro supplanted Batista.

<aside>The 26th of July Movement</aside>

The Castro regime. Batista's fall resulted as much from internal decay as from the challenges of Fidel Castro's 26th of July Movement (commemorating Castro's attack on the Moncada military fortress in Santiago on July 26, 1953) or from the Federation of University Students (later absorbed into the Young Communists Union) and

other groups. Castro had been a candidate in the aborted elections of 1952. His defense of his part in the Moncada attack, edited and published as "History Will Absolve Me," was a political manifesto. Released from prison in 1955, Castro and some friends went to Mexico to prepare for the overthrow of the Cuban government. An enlarged group, including the Argentinian revolutionary Ernesto (Che) Guevara, landed in Cuba in December 1956 and were almost annihilated in their first attack. From the Sierra Maestra the survivors fought a guerrilla campaign. When the Fidelistas took control on Jan. 1, 1959, they numbered fewer than 1,000.

The 26th of July Movement had vague political plans, relatively insignificant support, and totally untested governing skills. They quickly forged a following from among the poor peasants, the urban workers, the young, and the idealistic of all groups. The Communist Party of Cuba, dating to 1925, assumed the dominant political role, and the state modeled itself on the Soviet-bloc countries, becoming the first socialist state in the Americas.

The first stage of the new regime was dominated by the progressive dissolution of capitalism, between 1959 and 1963. In those confusing and difficult years, the government eliminated the remnants of Batista's army as well as the former labour unions, political parties, and associations of professional persons and farmers. New institutions emerged: the Confederation of Cuban Workers (reconstituted 1970), the National Institute of Agrarian Reform (founded 1959), the Cuban Institute of Cinematic Art and Industry (1959), the Central Planning Board (1960), the Committees for the Defense of the Revolution (1960), the Federation of Cuban Women (1960), the National Association of Small Farmers (1961), the Revolutionary Armed Forces (1961), the National Union of Cuban Writers and Artists (1961), the Young Communists (1962), and others. The nationalization of hundreds of millions of dollars in U.S. property and private businesses provoked retaliatory measures by the U.S. government, including a trade embargo, an unsuccessful invasion by Cuban exiles at the Bay of Pigs in south central Cuba (April 1961), and unexecuted plots to assassinate Castro.

<aside>Nationalization of U.S. interests</aside>

Within Cuba the erratic drift toward socialism and the growing economic dependence on the Soviet Union divided both the leadership and the country at large. Hundreds of thousands of Cubans, especially from among the skilled and the wealthy, emigrated to Spain, the United States, and other countries. The National Institute of Agrarian Reform tried and failed to diversify the economic base, and the constant mobilization for war frustrated effective long-term planning. Attempts to foment revolution elsewhere, especially in the Dominican Republic, Venezuela, and Bolivia, alienated Cuba from most of the other Latin-American states.

Castro visited the Soviet Union during 1963, but the next two years witnessed a period of ideological instability as the government consolidated its domestic position. A second agrarian reform ended attempts to diversify the economy. Shortages became acute. A professional army replaced the militias as the bastion of national defense. The meeting of Latin-American communists in Havana in November 1964 and the civil war in the Dominican Republic in April 1965 (which brought U.S. military intervention) renewed the Cuban intent to export their revolution.

Between 1965 and 1970 the revolution experienced a third, more radical phase. Cuba began to assume a significant leadership role among the so-called Third World countries; in 1979 Cuba was host to the summit conference of nonaligned nations and was its chairman from 1979 to 1982. By 1968 there was a strong campaign against bureaucrats and a renewed attack on private property, as hundreds of small businesses were nationalized. Military officers moved into the highest ranks of government, industry, and the party.

Material conditions improved slightly during the 1970s. The revolution institutionalized itself along orthodox Soviet lines. Bottlenecks and shortages were substantially eliminated, and diplomatic isolation gave way to technical, commercial, or military assistance between Cuba, the Soviet Union, and the states of Africa, Latin America, and

Political reorganiza-tion

the Caribbean. The political system was reorganized. In 1976 a new constitution and a new electoral code created 14 provinces (instead of six) and 169 municipalities (including the Isla de Pinos, now Isle of Juventud). Fidel Castro became president of the Council of Ministers and the State Council (combining the offices of president of the republic and prime minister). Nationwide elections in 1976 returned municipal assemblies, which then elected members to the provincial and national assemblies. (F.W.Kn.)

Castro reestablished full diplomatic relations with the Soviet Union in 1960, and until 1991 the Soviet Union bought the major portion of the Cuban sugar crop, generally at a price above that of the free world market. Soviet aid to Cuba in loans, petroleum, war matériel, and technical advice amounted to several billions of dollars annually. In 1968 Cuba endorsed the Soviet invasion of Czechoslovakia, but Cuba lost considerable influence among the nonaligned nations when it supported the Soviet invasion of Afghanistan in 1979.

Soviet military support was crucial in the early years, and Soviet maneuvers often aroused strong antagonism from the United States. The installation of Soviet missiles in Cuba in 1962 brought the United States and the Soviet Union to the brink of war as the U.S. government set up a naval blockade of the island and demanded the removal of the missiles. In 1979 the United States objected to the presence of Soviet combat troops in Cuba.

In the late 1960s the Cubans began to redefine themselves as an "Afro–Latin-American people." By the 1980s this new definition was accompanied by assistance to several nations in Africa, Latin America, and the Caribbean. Cuban military assistance influenced civil wars in Angola and Ethiopia, but civilian personnel made contributions elsewhere in Asia and Latin America.

U.S.–Cuba emigration agreement

Emigration from Cuba to the United States became an issue beginning in the 1980s; and in 1987 the two countries signed an agreement allowing for the emigration of 20,000 Cubans annually to the United States.

Although there has been an overall improvement in Cuba–U.S. relations since the revolution, the U.S. trade embargo imposed in the early 1960s remained essentially in force. U.S. investigations concerning the condition of political prisoners in Cuba and the propaganda broadcasts beamed from the U.S. Radio Martí since 1985 continued to cause agitation. In the meantime Cuba–U.S. relations worsened when the United States invaded the island of Grenada in 1983, killing a number of Cubans and expelling the remainder of the Cuban aid force from the island. Cuba gradually withdrew its troops from Angola in 1989–91.

Cuban-Soviet relations deteriorated as a result of the liberalization in the late 1980s of Soviet political, economic, and social policies. The Soviet Union initiated the withdrawal of its troops from Cuba in September 1991 over the latters' objections that the withdrawal would compromise the nation's security. When the Soviet Union was dissolved in 1991, the already troubled Cuban economy suffered further from the loss of vital military, economic, and commercial support that had in effect constituted subsidies. Amid severe internal shortages, and with unrest and dissatisfaction growing, Castro declared a "special period in peacetime" of food rationing, energy conservation, and reduction of public services. Unemployment increased, and shortages of food, medical supplies, raw materials, and fuel were exacerbated by the ongoing U.S. trade embargo.

In 1993 the government legalized small businesses such as *paladares* (family restaurants), private employment, and the use of foreign currency (notably remittances from abroad). The following year independent farms and farmers markets were encouraged. The government also attracted foreign capitalists, including Canadian and Spanish hoteliers. Christmas was restored as a national holiday in 1997, in anticipation of a visit by Pope John Paul II the following year. The economy improved markedly, but the future of socialism was increasingly questioned.

In 1996, after Cuban jets shot down two small private aircraft from Florida, the U.S. Congress passed the Helms-Burton law, which threatened sanctions against foreign-owned companies investing in Cuba. In 1999 prominent dissidents were jailed and repressive laws enacted, prompting further international criticism. However, Cuba subsequently benefited from a major economic agreement with Venezuela, and Fidel Castro maintained a firm grip on power. (F.W.Kn./Ed.)

For later developments in the history of Cuba, see the BRITANNICA BOOK OF THE YEAR.

Dominican Republic

The Dominican Republic (República Dominicana) occupies the eastern two-thirds of Hispaniola, the second largest island of the Greater Antilles archipelago in the Caribbean Sea. Haiti occupies the western third of the island. Hispaniola lies between the islands of Cuba to the west and Puerto Rico to the east and is situated about 670 miles (1,080 kilometres) southeast of Florida and 300 miles north of Colombia and Venezuela. The northern shores of the Dominican Republic are washed by the Atlantic Ocean, while the southern shore is bordered by the Caribbean Sea. Between the eastern tip of the island and Puerto Rico runs a channel called the Mona Passage. The republic has an area of 18,704 square miles (48,443 square kilometres; including 63 square miles of adjacent islands). The capital is Santo Domingo.

The country, although small, occupies a strategic position on major sea routes leading to the Caribbean and the Panama Canal. Between 1930 and 1961 the republic's history was dominated by the repressive dictatorship of Rafael Trujillo—a ruler who nevertheless liquidated the national debt and modernized industries. Yet, the human costs were excessive. Since the Trujillo regime large numbers of Dominicans have remained in poverty with little promise of improvement.

PHYSICAL AND HUMAN GEOGRAPHY

Major mountain ranges

The land. *Relief.* There are five distinct upland areas running along a northwest-to-southeast axis. The Duarte Peak in the major Cordillera Central (Central Highlands) is the highest point in the West Indies, rising to 10,417 feet (3,175 metres). There are also a smaller range, the Cordillera Septentrional, which runs parallel to the northwest coast, and two lesser ranges in the southwest. Another minor upland area, the Cordillera Oriental (Eastern Highlands), lies in the northeast. The extreme northwest and the extreme southwest are dry, low, and desertlike. The southeastern region consists of rolling lowlands.

Drainage. The Yaque del Sur River empties into the Bay of Neiba, draining the Cordillera Central to the south, while the Yaque del Norte River drains the northern slopes, flowing into the Bay of Monte Cristi. The eastern part of the island is drained by the Yuna River, which flows into Samaná Bay, and by the Ozama River, the mouth of which is near Santo Domingo, on the south coast. The salt lake of Enriquillo, about 23 miles long and 11 miles wide, is the country's largest natural lake.

Soils. Soils vary, but those of the upland areas mainly derive from metamorphic and sedimentary rocks. Lowland soils are of recent alluvial origin, except in the southeastern savanna (grassland) area, where they consist of sedimentary deposits. Soils are generally fertile except in the far southwest, in the Pedernales region.

Climate. The Dominican Republic lies well within the tropical zone, but temperatures vary according to elevation and the northeast trade winds. The heaviest precipitation is in the mountainous northeast, where the average rainfall is more than 100 inches (2,540 millimetres) a year. As the trade winds pass over the various mountain ranges, they lose their moisture until, in the far western part of the country, along the Haitian border, less than 30 inches of rain falls annually. The Dominican Republic is often in the path of tropical storms and hurricanes, which originate in the mid-Atlantic and southeastern Caribbean from August until October each year.

Tempera-tures

In spite of local variations, the country as a whole enjoys a relatively mild and pleasant climate. The annual mean temperature is 77° F (25° C). Temperatures rarely rise above 90° F (32° C), and, even in the heart of the highest

central mountain range, the overall mean is only about 69° F (21° C). Very cold temperatures are unknown.

Plant and animal life. Vegetation varies considerably. The mountains are still largely forested with pines and hardwoods, although during the past century the lower and more accessible slopes were practically denuded of trees by commercial lumbering. In the drier regions low shrubs and scrubby trees predominate, but, as rainfall increases, grasslands and dense rain forests occur. The royal palm appears prominently throughout much of the country.

Cultivation of a wide variety of crops has largely replaced the natural vegetation in many areas—particularly in the more fertile upland valleys and on the lower mountain slopes. Mangrove swamps line some coastal areas, while elsewhere, particularly along the northern shore, sandy beaches of great beauty are to be found.

Wild animal life is not abundant, although for several centuries cattle and goats, introduced by the early Spanish colonists, ran wild on the grasslands and in the desert areas. Alligators are found near the mouths of the Yaque rivers and in the waters of Lake Enriquillo. A great variety of birds, including ducks, are hunted. Fish and shellfish inhabit the surrounding waters but have not been exploited commercially. Sport fishing, however, is an important tourist activity.

Hubertus Kanus—Photo Researchers

Housing along the Yaque del Norte River at Santiago, Dom. Rep., is spanned by a modern bridge.

Settlement patterns. The greatest population density, apart from the metropolitan area of Santo Domingo, is in the area referred to as the Cibao Valley, which extends across the north from the Samaná Peninsula in the northeast, north of the eastern and central mountain ranges and south of the Septentrional range, to Monte Cristi in the far northwest. South of the Cordillera Central lies an alluvial plain where rice is grown; its population is centred on San Juan de la Maguana. Many of the inhabitants of the town of Azua and its environs are the descendants of immigrants from the Canary Islands.

The southeastern savannas, now largely under sugar cultivation, are inhabited by settlers of predominantly European ancestry—descendants of cattle herders and families who owned small ranches. The southeastern coastline itself, however, is increasingly inhabited by blacks from other West Indian nations who have come to work on the sugar plantations, in the mills, or on the docks. Most of these are temporary or seasonal workers, many from Haiti.

Although villages exist, the more common rural settlement pattern is a scattered neighbourhood—perhaps clus-

tered about a small store or church. Settlements frequently stretch along roadsides, with cultivated patches behind the houses; there are still many households so isolated from major or even minor roads that they can be reached only on foot or by horseback.

The Dominican Republic still has a large rural population, but it has diminished. Some 55 percent of the population is now estimated to live in urban sites, the country having experienced one of the highest urbanization rates in the world since the late 1950s. The largest of the urban centres is Santo Domingo, the capital city, followed by Santiago, which vies with the capital in political, cultural, industrial, and commercial importance. Other major population centres include San Francisco de Macorís and La Vega in the Cibao Valley, San Pedro de Macorís and La Romana on the south coast, and Puerto Plata on the north.

The Dominican Republic also has been subject to a high rate of out-migration, primarily to New York City. During the 15-year period 1965–80 it has been estimated that some 400,000 people, or about 8 percent of the total population, chose to emigrate, principally to improve their economic situation. Many of the emigrants found extralegal ways to gain entry to and remain in the United States. The outward flow of people alleviated the strain on home resources and at the same time provided remittances of cash and goods that assisted the welfare of those who stayed at home.

The people. The racial composition of the republic is predominantly mulatto (*i.e.*, of mixed European and African ancestry), the Amerindian element having been largely decimated by disease, warfare, and the effects of forced labour shortly after the arrival of the first Europeans.

The colonizing whites, mostly Spaniards, were joined in the 19th and 20th centuries by immigrants from East Asia and from such European countries as France, England, and Germany, as well as by small numbers of Sephardic Jews and Middle Easterners. The Mediterranean immigrants at first competed with Chinese peddlers and shopkeepers in the rural areas, but most have moved to the cities, where they occupy positions in commerce and industry. The Chinese particularly established themselves in the hotel and restaurant industry. A small group of Japanese developed truck farming in the Constanza Valley even before World War II, but their descendants are now to be found throughout the republic. Intermarriage among all of these groups has blurred, but not erased, their ethnic origins.

The exact African heritage of the large black population is unknown. Many of them arrived with or soon after the conquistadors, serving as slaves in the mines and the early sugar enterprises. Others drifted over from the French colony of Saint-Domingue (now Haiti) both before and after that area achieved its independence. Indeed, the entire country was briefly under Haitian rule early in the 19th century. There has long been a problem with Haitian squatters who cross over without immigration papers along the entire mountainous frontier between the two countries; other Haitians imported as cane cutters in the south have found ways to remain after their contracts expire. Thus, the African-American cultural influence is strong, especially among the lower socioeconomic classes, which tend to be darker-skinned than their more affluent compatriots.

The Spanish language has always been predominant, although English is becoming more common due to the massive emigration to the United States, which has been accompanied by continual visiting back and forth, plus some repatriation. Among Haitian immigrants, a French creole is spoken.

Most of the population is Roman Catholic. That religion exerts a marked influence on cultural life at national, local, and family levels. The religious beliefs and practices of the rural populace are rooted in the cultures of both the early Spanish and African communities. A small percentage of the population is Protestant, although it has been growing in recent years; there are a few practitioners of Judaism and other religions.

The rate of population increase is greater than that of most of the West Indian islands. Birth rates in both the

---

Forested areas

Urban centres

Language

Dominican Republic and bordering Haiti are substantially higher than those of nearly all of the neighbouring islands; but the death rate for the Dominican Republic, although higher than those of most Caribbean islands, is considerably less than that of Haiti.

The economy. Agriculture continues to be the basis of the Dominican Republic's economy, although that sector has been giving way to manufacturing. During the Trujillo regime, from 1930 to 1961, the Trujillo family largely controlled both agriculture and industry and, thus, the economy. Since 1961 most Trujillo enterprises have remained under governmental control. However, private industry has outstripped these in contributing to the gross national product, and there has been considerable diversification in recent years. As in many other Latin-American countries, this has been made possible through foreign loans, which have placed the country in serious debt.

Import duties and excise taxes constitute the largest part of public revenue. Other government income derives from income, sales, and road taxes, as well as vehicle licenses.

Trade unionism has not been important historically in the Dominican Republic but has become increasingly significant with the growth of the manufacturing sector since the mid-20th century. During Trujillo's rule, there was one so-called confederation of workers, which, in fact, was no more than a company union. After 1961 the labour movement developed rapidly, with unions tending to organize on the basis of political affiliation. Many are affiliated with international labour organizations.

There are also a number of employer associations, including the U.S. and Dominican chambers of commerce, as well as associations of cattle growers, sugar producers, and tomato growers. A number of factories and industries have associations for workers and management.

Resources. The most important resource of the Dominican Republic is the land, which is the foundation of the heavily agricultural economy. About one-third of the land is agricultural and under permanent cultivation. Pastures and meadows make up the largest land use category, more than 40 percent, and forests account for more than one-tenth of the land area. A number of minerals are known to be present but—with the exception of nickel, bauxite, gold, silver, gypsum, and iron ore—have not yet been highly developed commercially. Salt, largely from salt deposits near Enriquillo Lake, is also produced in commercial quantities. A smaller salt-producing enterprise, based on the evaporation of sea water, has also been of some importance at Monte Cristi. Other minerals of potential importance include sulfur, coal, titanium, molybdenum, cobalt, tin, oil, and zinc.

The Dominican Republic is one of the relatively few sources of quality amber in the Western Hemisphere. Although it has not yet been extensively exploited, craftsmen produce distinctive jewelry for the local and tourist trade.

Unexploited biological resources are few, but proper management of agricultural lands, forests, and grazing areas has been encouraged to improve productivity.

Agriculture, fisheries, and forestry. Unlike most other Caribbean nations, the Dominican Republic produces much of its own basic food, as well as a considerable amount for export. The agricultural base of the economy is heavily dependent on the growth and processing of sugarcane. Raw sugar accounts for the largest share of export earnings, but there is also a smaller external market for rum, molasses, and bagasse. Tobacco, cocoa, coffee, rice, tomatoes, hides, bananas and other tropical fruits, root crops, and sorghum are other important agricultural exports. The tourist trade has stimulated the agricultural sector to improve the production of animal products, including chickens, eggs, pork, and beef, as well as dairy products in general.

Although the possibilities for a large-scale export-oriented fishing industry seem limited by the relative scarcity of marketable fish in nearby waters, the supply has been sufficient for local needs, and big-game fishing has been an additional tourist attraction. Forestry is of little consequence.

Industry. The main industry is sugar production. The processing of foods and beverages is well developed. Locally made textiles and finished clothing—particularly

(margin: Arable land)

(margin: Manufacturing)

shoes, shirts, and hats—have replaced some imports. Wooden, metal, and plastic furniture has become important on both domestic and foreign markets. Some factories assemble products under contract with foreign, usually U.S., companies. There are many other small industries manufacturing traditional consumer goods such as soap, candles, rope, cigars, concrete blocks, cement, and tiles. Petroleum refining has grown in importance.

Tourism has become, after sugar, the most important source of foreign exchange. For Americans, particularly, the country has become attractive for its liberal divorce code. But the favourable climate, beautiful beaches, restored Spanish colonial architecture, and relatively low prices draw their own clientele.

Trade and finance. The Dominican Republic's heavy dependence on sugar exports makes the balance of trade susceptible to worldwide fluctuations in sugar demand and prices. The government has taken steps to diversify the economy and to lessen the dependence on sugar exports. The largest strides in diversification have been made in the mining sector, in which exports of gold, silver, bauxite, and ferronickel account for about one-third of all export earnings, and in the light industrial sector, which exports clothing, electronic equipment, leather goods, and industrial staples. In addition to petroleum products, the country's chief imports are foodstuffs and manufactured goods. For cultural and geographic reasons, the country does not belong to any of the four major economic market integration systems of Latin America. The United States and Venezuela are the two chief suppliers of imports, while the United States receives the bulk of Dominican exports.

The monetary system is managed by the Central Bank, which maintains a gold and foreign currency reserve and administers exchange rates relative to the U.S. dollar. The private banking system is well developed, and several financial institutions, loan companies, and insurance agencies operate in the urban centres.

Transportation. Santo Domingo is the hub of a transport system that facilitates the flow of both people and goods to virtually all parts of the republic. Although the highway between the capital and the Cibao region is heavily traveled and in poor condition, secondary roads are generally good for a developing country.

Modern buses as well as a large fleet of private taxicabs provide transportation both within and between cities. Most goods are transported by truck to the important market centres.

A government-owned railroad line runs through the eastern half of the Cibao from La Vega to the port of Sánchez on Samaná Bay; it carries only freight. Most of the country's other railway lines are privately owned and serve the sugar industry. There is no passenger service.

There are international airports at Punta Caucedo, about 15 miles east of Santo Domingo, and at Puerta Plata on the northern coast. A secondary airport in Santiago handles small jets and propeller planes. Other airfields around the country are open to small civilian craft. The government-owned airline, Dominican Aviation Company, operates flights to San Juan (Puerto Rico), Curaçao in the Netherlands Antilles, New York City, and Miami and also makes local flights. Airlines now handle most passenger traffic to and from the Dominican Republic, but goods are exported and imported primarily by sea. Samaná Bay is one of the finest and largest natural harbours in the entire Caribbean. Until the 20th century the primary commercial ports lay along the northern coast, but, with the rise of the sugar plantations in the south, the ports of Santo Domingo, San Pedro de Macorís, and La Romana have increased in importance. Most general goods pass through Santo Domingo, but sugar is largely exported through the ports of San Pedro de Macorís and La Romana. Important historically, the ports of Monte Cristi and Sánchez in the north are now almost defunct. Only Puerto Plata in the north retains its commercial importance; it is still viable largely because of the tobacco, coffee, and cacao interests in the Cibao region. Barahona ships bauxite, gypsum, and salt but receives few imports.

Administration and social conditions. *Government.* The executive power is vested in a president, who is also com-

(margin: Airports)

mander in chief of the armed forces, and a vice president. There is a Senate and a Chamber of Deputies. The Senate is composed of one representative from each province and one from the National District. The Chamber of Deputies reflects the size of the population but has no fewer than two representatives from each province and two from the National District. The present (1966) constitution, like its numerous predecessors, guarantees human rights, prescribes the division of governmental powers, and provides for popular sovereignty. It also accords suffrage to all Dominicans of either sex over 18 years of age, unless they are members of the armed forces or the police. During the Trujillo regime the armed forces were used to preserve the dictatorship, and even afterward the armed forces have played a role in government.

Historically, the various constitutions have provided special emergency powers for the president that have made it possible for the executive to supersede the legislative and judicial branches of the government should the president deem it necessary. While retaining provisions for emergency executive powers, each successive constitution has, nevertheless, expanded the social and economic rights guaranteed in earlier documents. A formal relationship between the Roman Catholic church and the government, incorporated in earlier constitutions, has now been eliminated. The right to private property is guaranteed but is limited by the right of the state to expropriate for the general good. Terms for national elected offices are four years, and incumbents may seek reelection.

The nation is divided into 29 provinces and one Distrito Nacional ("National District"). The central government administers the outlying provinces through governors appointed by the president. Each province elects representatives to the bicameral national congress. Internally, each province is subdivided into municipalities that elect their own councils and enjoy considerable local autonomy.

Justice. The legal system is based upon the Napoleonic Code. There is a series of regular courts, the judges of which are appointed by the Senate and may have no other public employment. These courts, with the exception of the land and commercial courts, have jurisdiction over both criminal and civil matters.

In criminal cases the judicial process begins with an investigation, generally conducted by an investigating judge. This is followed by the trial proper, conducted by the appropriate court. Appeals are made to a superior court and may finally be considered by the Supreme Court, composed of nine justices.

Education. The more isolated and rural the population, the less accessible are educational institutions, although education is free and compulsory for children between the ages of seven and 14. Primary schooling ordinarily lasts six years, although less may be offered in rural areas. This is followed by a two-year intermediate school and a four-year secondary course, after which a diploma called the *bachillerato* is awarded. Relatively few lower-income students, however, succeed in reaching this level, since the system is designed to encourage middle- and upper-income students to prepare for admittance to a university. Most wealthier students attend private schools, which are frequently sponsored by religious orders. Some public and private vocational education is available, particularly training in the field of agriculture, but this too reaches only a very small percentage of the population.

The Autonomous University of Santo Domingo, founded in 1538, is the oldest university in the New World. It is free of both governmental and religious control, although most of its funds are from the national budget. Costs are low and even poor students may attend, if they have been fortunate enough to have secured the requisite primary and secondary preparation.

The Pedro Henríquez Ureña National University, located in Santo Domingo, enjoys the support not only of the Roman Catholic church but also of private endowments and receives funds from the national government as well. The Madre e Maestra Catholic University in Santiago is similarly supported both by the Roman Catholic church and through private and public endowments. The Central University of the East in San Pedro de Macorís and

The universities (margin note)

the Technological University of Santiago were founded in 1970 and 1974, respectively.

Health and welfare. Health conditions among the poorer classes in both rural and urban zones are characterized by a generally unsanitary environment, inadequate health services, and poor nutrition. As a result, infectious and parasitic diseases are common, and infant mortality is high. Hospital and trained medical personnel are available only in the larger cities and towns. In the rural areas, home remedies and the professional services of practitioners of traditional local medicine are the only means of preserving or restoring health. Cases of severe illness may be taken to the nearest urban centre, where hospitalization is free. The tendency, however, is to take this measure only in extreme cases, often when death is already imminent.

Housing is considered by Dominican planners to constitute one of the most serious problems in the country. On the sugar plantations in the south, barracklike housing is provided for temporary workers, but more permanent employees frequently have their own small huts, or *bohios,* often on company-owned land. These may be little more than a lean-to of palm leaves and bamboo. Others, more sturdy, may have double-reed walls filled with rubble and plastered with mud.

In the Cibao, a relatively prosperous zone, houses are built solidly of palm board or pine and are frequently painted and decorated, with shutters and lintels in contrasting colours. Roofs are most often covered with sheets of zinc or tin but, in poorer households, may be thatched. A prosperous family may have a concrete floor, but most are of packed earth.

In the cities are the squatter settlements and poverty-stricken inner-city ghettos characteristic of most rapidly urbanizing underdeveloped countries. Dwellings may be built of cardboard, discarded inner tubes, and any other materials the inhabitants may scavenge.

Also in the cities are districts with well-appointed modern houses, occupied by members of the new commercial and industrial elite, as well as by the more traditional land-based oligarchy. Government programs, often funded with international loans, have financed housing construction for lower- and middle-income families.

Social conditions in the Dominican Republic resemble those found in other underdeveloped Latin-American nations. Small farmers rarely eke out more than a subsistence crop and most often must supplement this by the sale of handicrafts; products include baskets, pottery, rocking chairs, straw hats, and foodstuffs. These items are either sold to middlemen, who market them in towns, or are displayed and sold along the roads and highways.

By far the largest proportion of the population belongs to the lower-income group. This category includes the small farmers, as well as landless agricultural workers, itinerant merchants, and unskilled manual labourers.

Although most Dominicans, as well as some outside observers, have insisted that there is no traditional oligarchy, there nevertheless exists an intellectual and economic elite that constitutes a tiny fraction of the total population. An emergent middle-income group has also developed.

Cultural life. *Folk and fine arts.* It is difficult to define any particular and unique cultural tradition that may be labeled Dominican. There are, nevertheless, some cultural items worthy of special mention. Music, especially when accompanied by dancing, is important at all social levels and in all regions. The most typical forms are those with clear African antecedents, especially in their rhythms. There are also folk songs and tunes deriving from Spain and the Middle East. The merengue is a particularly popular dance, followed closely by the bolero. The guitar is probably the most popular instrument, but in some rural areas flutes and homemade marimbas are also common. Young people have been influenced by reggae and other modern African-American musical developments, as well as by the different forms of rock music. There is no highly identifiable Dominican national costume.

The universities, as well as numerous private literary and cultural organizations, have long fostered an interest in the classical European arts of music, painting, drama, and literature. The country fosters a symphony orchestra, legit-

Rural housing (margin note)

Musical tradition (margin note)

imate theatres, and art museums. Numerous local painters produce canvases ranging from exuberant Haitian-style primitives to abstracts and Impressionism.

Literature. A national spirit in Dominican literature began to develop during the 19th-century Haitian occupation and was led by Félix María del Monte, who was best known for his poetry. This trend was continued in the struggle against Spain, that experience being classically represented in the work of Manuel de Jesus Galván, who depicted Spanish settlers' cruel treatment of the Indians. In the early 20th century, writers such as Américo Lugo and Gaston Gernando Deligne were influenced by modernism and broke from the 19th-century styles and themes although the U.S. occupation revived some nationalist expression. Contemporary writers have focused to some degree on everyday Dominican life, but a social protest literature also emerged as represented by the works of the reformer Juan Bosch, written largely from exile.

Recreation. Important holidays are largely defined by the calendar of the Roman Catholic church, but the way in which they are celebrated reveals a mixture of official church and ancient folk traditions. Carnival, observed during several weeks preceding Lent, is especially colourful in Santiago. Masked and costumed men and boys circulate in the streets, hitting each other with inflated pig and goat bladders and chanting traditional rhymes intended to provoke each other to what is today usually only playful retaliation. Their masks are usually homemade and constitute a recognized art form in the country. During the final few days of carnival, organized and elaborately costumed groups of players of both sexes perform in the streets in return for handouts of rum and cash.

Organized team sports are popular, especially baseball, which was introduced by Americans during their occupation of the country in 1916–24. Major league players from the United States do spend their winters in the Dominican Republic, playing in local professional leagues. Many of the professional baseball players in the United States are themselves of Dominican birth. Cockfighting remains a traditional and popular spectator sport among men, although it is disapproved by the authorities.

Press and broadcasting. During the long Trujillo regime, freedom of expression in the press was severely restricted, but since that time the constitutional guarantees have been more or less upheld. Among the island's several daily newspapers, the most important are published in Santo Domingo and include *El Caribe,* founded in 1948, and

Listín Diario, founded in 1889. A variety of U.S. newspapers and periodicals are also available. Radio and television broadcasting is supervised by the general director of telecommunications. The main stations are also in Santo Domingo, one of them—Dominican Radio Television—being owned and operated by the government. (N.L.G.)

For statistical data on the land and people of the Dominican Republic, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

At the time of Columbus' first landing in 1492, the Caribs, a people who had apparently originated on the South American mainland and migrated to the Greater Antilles (and for whom the Caribbean Sea is named), were preying upon the Taino (Arawak), who had previously settled there. These Indians were less advanced socially and culturally than were the large-scale Indian civilizations in Mexico, Guatemala, or Peru.

Hispaniola was visited by Columbus on his maiden voyage. A colony was established on the north coast, but the first settlers were slaughtered by the Indians. Returning, Columbus established a second colony; but reports of abundant gold farther south quickly led to the abandonment of the northern outpost and to the founding of Santo Domingo city on the Caribbean coast.

Colonial era. Hispaniola was the first area in the New World to receive the full imprint of Spanish colonial policy. The oldest cathedral, monastery, and hospital in the Americas were established on the island, and the first university was chartered there. The earliest experiments in Spanish imperial rule were conducted here. Class and caste lines were rigidly drawn; the Roman Catholic church served as the strong right arm of temporal authority. A cruel, exploitative, slave-based society and economy came into being. The first "revolution" in the New World was also recorded on Hispaniola.

During the first half century of Spanish rule, Hispaniola flourished, for its rich mines and lush lands yielded abundant wealth, and it served as the administrative centre for Spain's burgeoning American empire. But the more lucrative conquests of Mexico and Peru soon turned it into a poor way station. Its Indians were decimated, gold and silver were more easily available elsewhere, and the more ambitious Spaniards emigrated.

For the better part of the next three centuries, Hispaniola remained a neglected, poverty-ridden backwater of

the Spanish empire. Raids by British, Dutch, and French marauders and buccaneers further devastated the island. Eventually, the Spanish crown recognized France's claims to the western third of Hispaniola, a region that was renamed Saint-Domingue (later Haiti); a prosperous sugar-producing colony based on black slavery grew up there. The Spanish colony also experienced a boom in the 18th century as a by-product of Saint-Domingue's prosperity.

Power struggles and nationalism. In 1795 Spain ceded the eastern two-thirds of Hispaniola to France. Under French control the colony declined further. Meanwhile, a slave uprising had begun in Saint-Domingue, inflamed by the desire of mulatto freedmen for political rights and revolutionary currents in France. Led by Toussaint-Louverture, the Haitians not only succeeded in throwing off French rule but soon overran parts of the previously Spanish eastern end of the island as well, instilling terror in the white ruling class. For a time French, British, and various Haitian armies all vied for control of Hispaniola. In 1809 the colony was reunited with Spain, but in 1821 a group of Dominicans declared independence.

Haitian occupation. Within weeks Haitian troops under Jean-Pierre Boyer (president of Haiti, 1818–43) again overran the eastern part of the island, initiating a 22-year occupation (1822–44). Haitians forced out the traditional ruling class and all but obliterated the western European and Hispanic traditions. In addition, Haitian troops arbitrarily confiscated supplies, and ethnic tensions caused further resentment. Dominican historians have portrayed the period as cruel and barbarous, but Boyer also freed the slaves, and his administration was generally efficient.

In the 1830s Juan Pablo Duarte—the father of Dominican independence—initiated a rebellion that gained strength following an earthquake in 1842 and the outbreak of civil war in Haiti. In 1844 independence was achieved.

Caudillos. From 1844 until 1899 several caudillos (military strongmen) dominated the Dominican Republic, most notably Pedro Santana and Buenaventura Báez. Santana's maladministration and heavy military spending (to ward off Haitian attacks) bankrupted the nation, and in 1861 he invited Spain to reclaim its former colony. Santana was thoroughly discredited as a traitor, and Spain withdrew its troops after a brief occupation (1861–65) and a series of battles against patriotic forces. Báez then approached the United States with a protectorate plan. President Ulysses S. Grant favoured annexation, but the U.S. Senate failed to ratify the treaty by one vote.

The instability continued during the 1870s. Ulises Espaillat, an idealistic reformer, was elected president and then overthrown in 1876, marking the country's first democratic government. Báez returned to the presidency for a fifth time (1876–78) but was also forced out. A period of civil
Ulises unrest ensued, out of which Ulises Heureaux emerged and
Heureaux dominated the country from 1882 to 1899. His regime built new roads, dug irrigation canals, and brought in foreign investment, particularly major sugarcane producers from Cuba; like his predecessors, however, he ruled with a dictatorial hand.

Heureaux was assassinated in 1899 by Ramón Cáceres, a rival politician. New leaders took over and were in turn forced out, including Juan Isidro Jiménez and Horacio Vásquez—two bitter rivals—and Cáceres himself.

Intervention by the United States. Meanwhile, the United States had replaced Europe as the republic's major trading partner. However, U.S. and European investors became alarmed by the nation's deteriorating financial situation. In 1905 the United States began to administer the Dominican Republic's customs agency, using it, in part, to pay off the republic's European creditors. The United States subsequently took over the nation's government.

During the occupation (1916–24) the U.S. Marine Corps built roads, schools, and sanitation facilities, and the occupation government allowed U.S.-owned sugarcane companies to expand their operations. In addition, the Marines transformed the nation's cultural life by introducing chewing gum and baseball. However, the U.S. troops frequently abused their authority, and they created a constabulary that became the instrument by which future Dominican authoritarians would seize power.

Civil unrest, dictatorship, and democracy. In 1924 Horacio Vásquez won a U.S.-supervised presidential election, but he proved to be an incompetent and corrupt leader. A revolution was launched in 1930, triggered in part by the Great Depression. The military, under the firm control of its leader, Rafael Trujillo, let the revolution succeed. Trujillo then took power himself.

The Trujillo regime. The dictatorship of Trujillo (1930–61) was one of the longest, cruelest, and most absolute in modern times. Trujillo appointed family members to key offices, strictly enforced censorship and conformity laws, and ordered the murder of political opponents and the massacre of thousands of Haitian immigrants. Trujillo also dominated the church hierarchy and virtually every other element of society. He had Santo Domingo renamed Ciudad Trujillo, and he amassed a vast **Trujillo's** fortune for himself by taking ownership of virtually every- **fortune** thing he touched—land, airlines, manufacturers, and most sugarcane producers—in all as much as three-fifths of the nation's gross domestic product and workforce.

Most Dominicans deeply feared Trujillo and his secret police force, although they admired his bold personality— which they regarded as fundamentally Dominican—and his ability to control national affairs and promote public works projects. The country's stability attracted foreign investors and grants from the U.S. government, and the foreign news media extolled Trujillo's so-called "Dominican miracle" while downplaying his abuses and failures. In May 1961 the dictator was assassinated, and his heirs and followers were subsequently driven out.

Bosch, Balaguer, and their successors. In 1963 Juan Bosch and his moderately reformist Dominican Revolutionary Party (Partido Revolucionario Dominicano; PRD) took power; he was the first directly elected democratic and progressive president in the country's history. However, Bosch earned the enmity of the oligarchy and key U.S. officials, and he was overthrown. In 1965 a democratic revolution was sparked to oppose the country's return to oligarchic rule, but the United States, fearing the installation of a communist regime (as had happened in Cuba the previous decade), again occupied the country in 1965–66 and snuffed out the revolt.

The winner of the U.S.-organized 1966 elections was Joaquín Balaguer, a former Trujillo puppet. Balaguer became one of the main national figures for the next three decades, in the face of political challenges from Bosch and other progressive politicians. Balaguer's conservative rule, and his reelections in 1970 and 1974, reflected the power of the oligarchy and the military. As alternatives to conservative rule, many political activists supported the PRD or Bosch's newly founded Dominican Liberation Party (Partido de la Liberación Dominicana; PLD).

In 1978 Antonio Guzmán Fernández of the PRD defeated Balaguer and moved cautiously to implement reforms, but a hurricane devastated the country in 1979, and the faltering economy produced inflation and strikes. Guzmán was succeeded by another PRD candidate, Salvador Jorge Blanco, who served as president in 1982–86. Thus, the country completed eight years of truly democratic government, the longest in its history to that point. But Jorge Blanco was faced with falling sugar prices on world markets and government corruption. In an attempt to stabilize the economy, he initiated an unpopular austerity program. As a result, the aging (and by then blind) Balaguer was reelected president in 1986. The opposition claimed fraud after Balaguer's electoral victories in 1990 and '94, and, in the face of massive demonstrations, Balaguer agreed to step down in 1996. During his three decades of rule, he had provided stability and economic growth but at the cost of social injustices and human rights abuses.

Leonel Fernández of the PLD won the 1996 election. Fernández, who hoped to mark the end of caudillo rule, oversaw unprecedented rates of economic growth. Hipólito Mejía was elected president in 2000 as the PRD candidate. By the turn of the 21st century the Dominican Republic had developed a stronger base for democracy, with viable political parties, civilian-led governments, and a larger middle class; however, authoritarian and corporatist influences there remained strong. (H.J.Wi.)

For later developments in the history of the Dominican Republic, see the BRITANNICA BOOK OF THE YEAR.

Haiti

Haiti (Haitian Creole: Repiblik Dayti; French: République d'Haïti) is a republic in the Caribbean, situated in the western part of the island of Hispaniola. The native American Indian inhabitants called the island Ayti, meaning "Mountainous Land." Haiti's area of 10,714 square miles (27,750 square kilometres) occupies slightly more than a third of the island. The republic is located only 565 miles (910 kilometres) from the U.S. mainland. It borders the Windward Passage, a 50-mile-wide corridor between the northwest peninsula of Haiti and Cuba.

The coastline of Haiti is irregular and forms a long, slender peninsula in the south and a shorter one in the north. The two peninsulas are separated by the triangular-shaped Gulf of Gonâve, in the middle of which lies Gonâve Island. The border with the Dominican Republic runs north–south at a right angle with the main relief structures. The capital is Port-au-Prince.

Haiti won its independence from France in 1804, becoming the second country in the Americas, after the United States, to win freedom from colonial rule. It also became the world's first black republic, most Haitians being of African descent.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief, drainage, and soils.* Haiti is mountainous and rugged. Plains, which are quite limited in extent, are the most productive agricultural lands and the most densely populated areas. Rivers are numerous but short and most are not navigable. The seas around Haiti are noted for their striking coral reefs. The shores are generally rocky, rimmed with cliffs, and indented by a number of excellent natural harbours.

Chief mountain ranges

The backbone of the island of Hispaniola consists of four mountain ranges that extend in a west-northwest–east-southeast direction. In Haiti the most northern range occurs only on Tortuga Island ("Turtle Island"), which is shaped like a turtle shell. This island has an area of 69 square miles and in the 17th century was a stronghold of privateers and pirates from various nations.

Farther south the Dominican Cordillera Central becomes the Massif du Nord, a series of massive parallel ranges. On the top of one of its peaks, overlooking the city of Cap-Haïtien and the narrow coastal plain, stands the Citadelle Laferrière fortress built by King Henry Christophe at the beginning of the 19th century.

An interior basin, known as the San Juan Valley in the Dominican Republic and the Central Plateau in Haiti, occupies the centre of the island, south of the Massif du Nord. This plateau has an average elevation of 1,000 feet (300 metres), and access to it is difficult through winding roads. Through the basin and across a cut flows the Artibonite River, the longest river of the island. At Péligre a dam was built in the 1950s for the regulation of floods. A hydroelectric power plant began operation at Péligre in 1971. At the end of its course and before its delta mouth in the Gulf of Gonâve the Artibonite is used for partial irrigation of the triangular Artibonite Plain.

The third range, known as the Sierra de Neiba in the Dominican Republic and the Trou d'Eau Mountains (Chaîne du Trou d'Eau) in Haiti, towers over the narrow Cul-de-Sac Plain, which is immediately adjacent to Port-au-Prince and is occupied by the brackish Lake Saumâtre on the Dominican border. South of the Cul-de-Sac the fourth mountain range is called Sierra de Bahoruco in the Dominican Republic and Massif de la Selle in Haiti. It reaches its highest point at the Mount la Selle (8,773 feet). The prolongation of the range, the Massif de la Hotte (Massif du Sud), tops off at Macaya Peak (7,700 feet) farther west. Small plains lie north and south of these ranges.

Generally the mountains of Haiti are calcareous, although some volcanic formations can be found, particularly in the Massif du Nord. Karstic features (caves, grottoes, and subterranean rivers) are present in many parts of the country. Stairlike terraces on headlands are evidence of the correlative movements of the land and sea. A long fault line crosses the southern peninsula and passes just south of Port-au-Prince. Haiti is subject to periodic seismic activity, and Port-au-Prince and Cap-Haïtien were destroyed by earthquakes in 1751 and 1842, respectively.

The soils in the mountains are thin, and they lose fertility quickly when cultivated. The lesser hills have red clay and loam. Alluvial soils are found in the plains and valleys. Deforestation has caused much soil erosion.

Climate. Haiti has a warm, humid tropical climate characterized by daily variations of temperature that are greater than the annual variations. Average temperatures range from 75° F (24° C) in January and February to 83° F (28° C) in July and August. Temperatures vary with altitude. The village of Kenscoff at an elevation of 4,700 feet has an average temperature of 60° F (16° C), while Port-au-Prince, at sea level, has an average of 79° F (26° C). In winter frost can occur at high altitudes and mists are common.

Temperatures

Haiti is located on the leeward side of the island, which means that the influence of humid trade winds is not as great as in the Dominican Republic. The more humid districts are the windward northern and eastern slopes of the mountains. The leeward districts are drier, and some portions of the island receive less than 28 inches (700 millimetres) of rainfall per year. The northwest peninsula and Gonâve Island are particularly dry. There are two rainy seasons, lasting from April to June and from August to October. Some regions have only one rainy season, from May to November. Annual variations of rainfall can be large, causing droughts and famine. The southern peninsula is the part of the country that is most vulnerable to hurricanes. Hurricanes Allen (1980) and Gilbert (1988) were particularly destructive.

Plant and animal life. Much of the natural vegetation has been destroyed through clearing for agriculture, grazing, and the exploitation of timber during the last three centuries. This process has accelerated during the 20th century under population pressure. The virgin forests that once covered the country have been reduced to less than 10 percent of the total land area. Patches of forest remain in the Massif de la Selle, where one can see stands of handsome pines, and in the Massif de la Hotte, where an evergreen forest with giant tree ferns and orchids is preserved on the steep slopes of Macaya Peak. The *bayahonde* (a type of mesquite), cacti, and acacia form thorn brushwoods on the dry plains. On the coast the mangrove swamps have suffered substantially from an overexploitation for firewood and charcoal.

With the retreat of natural vegetation, wildlife has lost its habitat and shelter. Wild boars, guinea fowls, and wild ducks are no longer present, but caimans still inhabit rivers of the southern peninsula and flamingos can be seen around Gonâve Island. Flamingos are hunted without restriction.

Little has been done to conserve plant and animal life. No national or regional parks for the preservation of natural life have been established. The lack of conservation measures has been particularly unfortunate for coral formations and the animal life that surrounds them.

Settlement patterns. Haiti is densely populated. About three-quarters of the people live in rural areas and are dependent upon agriculture. Rural densities are above what is considered safe for good management of the environment and for the well-being of the people, given available technology. Migration to the cities takes its toll on the rural population, particularly drawing the young but population is still increasing in the countryside.

High rural density

The plains are more densely populated, but the hills and the steep mountains are covered with cultivated plots and human settlements. Although only 30 percent of the land is considered suitable for agriculture, more than 40 percent is under cultivation. Most farms are very small and are worked by their owners. Rural settlement is generally of the dispersed type, sometimes organized along the roads. The basic element is the homestead around which small plots are arranged. The small wooden-frame houses vary in design according to the region but are everywhere enclosed within a compound of four mud-daubed wattle

walls. The roof is either thatched or made of corrugated iron sheets. The furniture inside most houses remains restricted to necessities. Wealth is invested in land and cattle or is used toward the cost of voodoo ceremonies or to pay the school fees for children. Individual means of transportation are nonexistent. Peasant women usually walk to the nearest market "town" (*bourg*) or in some cases use crowded public trucks and buses.

These *bourgs* are characterized by their administrative and political functions. Most have a Roman Catholic church, police barracks, a court of justice, and a general store surrounding a square. Peasants and particularly peasant men have always been wary of visiting the *bourg*, where abuses in the form of fines, taxes, and forced military enrollment were all too frequent in the past.

Real urban life is limited to the capital and to five or six large towns. Port-au-Prince has more than six times the population of the second city, Cap-Haïtien. Port-au-Prince was founded in 1749 by royal order and became the capital of the colony of Saint-Domingue in 1770 because it was thought that its central location was more suitable for future development, defense, and commerce than the position of Cap-Français (later Cap-Haïtien) on the north coast. Because of fires and war damages, the city has retained few buildings from the colonial period and the early 19th century. Wooden gingerbread-style houses are a testimony of Victorian influences in the formerly fashionable districts of Bois-Verna and Turgeau. Since the 1960s the city has expanded. Pétionville, a middle-class suburb in the hills to the west, is now part of the metropolitan area. The vast majority of Port-au-Prince residents live on meagre incomes, and the signs of poverty are ever present. The sight of the shantytowns that surround the city, the squalor associated with the markets, and the general lack of hygiene are often disturbing to visitors.

Cap-Haïtien, which was once the capital of the colony, was founded in 1670. Its neat gridiron plan encompasses small blocks of old-fashioned houses with courtyards. The pace of life is much quieter than in Port-au-Prince, but its charm cannot conceal entirely the poverty demonstrated by hordes of beggars. The other major towns are Gonaïves, Les Cayes, and Jacmel.

The **people.** *Ethnic composition.* About 95 percent of Haiti's population is black; mulattoes account for most of the remainder, and whites make up a very small percentage. Because of its unique history, Haiti is different ethnically and culturally from other Latin-American countries and from the Spanish-speaking Caribbean nations. It shares with Guadeloupe, Dominica, Martinique, and Saint Lucia elements of a Creole culture, which is a mixture of Western and African influences.

Linguistic composition. Haitian Creole and French are the official languages. Creole is spoken by all Haitians and, with French, is used in drama, music, radio, television, politics, and religion. But written Creole is not widely accepted because the school system retains French as the main language of instruction. Creole is normally used in daily life, and French—mastered by perhaps 10 percent of the people—is used in more formal circumstances. Most of the vocabulary of Haitian Creole is derived from French, but its syntax is similar to that of some African languages and resembles the syntax of other creole languages of the Caribbean and the Indian Ocean.

Religions. The official religion of Haiti is Roman Catholicism, but the constitution allows the free choice of religion. About 80 percent of the population is Roman Catholic, and some 15 percent is Protestant. The Catholic clergy has gradually been "Haitianized" through the appointment of local priests and bishops. Although the official religion is respected, most Haitians are believers of voodoo (voudou, or *vodun*), a religion whose gods (*loas*) are derived from West African religions. Most practitioners do not find any contradiction between voodoo, which is above all a family cult, and Roman Catholicism.

Protestant ministers, however, consider their religion to be incompatible with the practice of voodoo. There are many Protestant sects because, in addition to the older denominations established in the early 19th century (Methodists, Episcopalians, and Presbyterians), new sects came to Haiti

during and after the U.S. occupation (1915–34), including Baptists, Seventh-day Adventists, and Mormons.

Demographic trends. Population growth is quite rapid in Haiti. Since the beginning of the 20th century there has been a fourfold increase in population. This expansion took place despite high rates of mortality, particularly infant mortality, that are due to poor health services. Life expectancy is among the lowest in the Americas.

Population growth is reduced by external migration. Since the early 1960s Haitians have been emigrating at a rate of some 50,000 per year. The main destinations for Haitian emigrants have been Cuba and the Dominican Republic. In the Dominican Republic there is a permanent population of persons of Haitian descent that lives under semiclandestine conditions. *Bracero* schemes allow temporary migrants for agricultural work and menial jobs. The United States has accepted qualified emigrant Haitian professionals since 1957 and industrial workers since 1965. Migration to the United States and Canada is still substantial. The high rate of emigration is due to poverty and to the narrowness of the job market.

The **economy.** Haiti is the poorest country in the Western Hemisphere. The limited resource base has been depleted, first through intensive colonial exploitation and later through unplanned development and corruption. Both the private sector and the state share responsibility for this state of affairs. A few multinational corporations are active in the country.

Resources. Gold and copper are found in the north of the country. Extraction of bauxite by Reynolds Metals Company at Miragoâne in the southern peninsula was discontinued in 1983. Drilling of sedimentary formations in the Gulf of Gonâve has not been followed by oil discoveries. Haiti is heavily dependent on energy imports. Hydroelectricity is not sufficient to satisfy current needs.

Agriculture and fishing. Agriculture is the largest sector of the Haitian economy, employing more than two-thirds of the labour force but accounting for barely one-third of the gross domestic product. Soil erosion and loss of fertility threaten the sustainability of agriculture. Cultivation on steep slopes poses a special problem since terraces are not usually constructed. Soils are often washed away after heavy rains. Recurrent drought and an absence of irrigation have kept production down. The ecological stress seems highest in the central region north and south of Port-au-Prince and in the northwest.

Export agriculture has traditionally been favoured by farmers and the state alike because it provides cash and hard currency. Coffee is the most important commercial product. The Haitian variety is an arabica coffee of the mild type. Coffee is sold through a system of intermediaries, speculators, and merchant houses, and in the past it was heavily taxed. Cocoa, mangoes, and essential oils for the cosmetics and pharmaceutical industries are also produced for export.

Sugarcane is the second major cash crop, but since the late 1970s Haiti has become a net importer of sugar. Only one sugar mill is still functioning, at Chancerelles, a suburb of Port-au-Prince. Most sugarcane is ground in rural distilleries that produce a substandard rum called clairin.

Population pressures have forced many farmers to concentrate on subsistence crops. Corn (maize), rice, sorghum, beans, and fruits and vegetables are the main food crops. Local food trade is conducted in rural markets and along the roads, but the size of these exchanges remains small.

Supply of food products has not kept pace with demand. The smuggling of food from the Dominican Republic has lowered consumer prices and injured Haitian farmers. Contraband is believed to account for 20 percent of Haiti's consumption. Following an outbreak of African swine fever in the early 1980s, the entire pig population was exterminated; this deprived many peasants of their only asset. New resistant breeds were subsequently introduced. Cattle breeding for milk and meat remains marginal, but there is some poultry production. Fishing is of limited importance because the fleet is ill-equipped.

Industry. The small domestic market has been a constraint on the growth of the manufacturing sector. After the overthrow of the Duvalier dictatorship in 1986 many

barriers to international trade were abolished and local industry has had to compete with imports from the Dominican Republic and the United States. Most industry is of the assembly type for reexport to the United States. The main items assembled are electronic components, baseballs, and clothing. The construction industry has flourished because of the high demand for housing.

Finance and trade. The financial situation of the country is precarious. The local currency, the gourde, is protected from devaluation by a convention with the United States signed in 1919 that established a fixed parity of five gourdes to one dollar. U.S. currency circulates freely in the country. The National Bank of the Republic of Haiti is the sole bank of issue and the principal commercial bank; there are a number of private and foreign banks. Total foreign debt is high. Government finances and the economy are largely dependent on aid from international agencies and from countries such as the United States, France, Canada, and Germany.

Import and export figures reflect a structural trade deficit. Exports of coffee have continued to dwindle rapidly, and exports of assembled goods vary from year to year according to competition. Major imports are food, machinery and vehicles, fuel, and textiles. About two-thirds of *Trading* the external trade is conducted with the United States, *partners* the rest being shared by the other Caribbean countries, France and other western European countries, and Japan. Internal trade, which is very active, has been disrupted by smuggling.

Transportation. The roads from Port-au-Prince to Cap-Haïtien, Les Cayes, and Jacmel have been paved, but generally inland transportation, hampered by rough roads, is difficult and often unpredictable. Trucks and buses offer irregular and costly service from Port-au-Prince to the provincial towns. Police checkpoints on the roads slow down traffic. Coastal boat service is minimal except from Port-au-Prince to the Jérémie district.

The Port-au-Prince harbour was modernized in the 1970s and '80s, and container facilities there handle most of Haiti's foreign trade. The Cap-Haïtien harbour has also been upgraded. There are a number of minor ports. The international airport at Maïs Gâté, 10 miles north of Port-au-Prince, provides direct service to North and South America, Europe, and the Caribbean.

Administration and social conditions. *Government.* A constitution approved by referendum in 1987 incorporated features of the U.S. and French constitutions. It provides

for a president who is directly elected by universal adult suffrage for a five-year term. The head of government is the prime minister, appointed by the president from among the members of the majority party of the parliament. The parliament consists of two houses, a Senate and a House of Representatives. Senators are elected for six years and representatives for four.

Law is based on the French Napoleonic Code, modified by legislation enacted during François Duvalier's presidency. The judiciary consists of four levels: the Court of Cassation, courts of appeal, civil courts, and magistrate's courts. Judges of the Court of Cassation are appointed by the president for 10-year terms.

The 1987 constitution provides safeguards against military rule. Military officers are disqualified from becoming candidates for political office, and the military and the police are no longer a combined force. In 1986 the National Security Volunteers—popularly known as the Tontons Macoutes—were officially disbanded. Nevertheless, the country remains highly vulnerable to military takeovers, which have played a large role in its history.

Education. Education is officially compulsory for children between the ages of seven and 13, but, because of a lack of facilities and staff, only about 40 percent of children in this age group attend school. More than 60 percent of the adult population is illiterate; the rate of illiteracy *Illiteracy* is higher in the countryside. The curriculum is based on the French model. This system has created a small elite, who have made distinguished cultural contributions, while most of the society remains relatively uneducated. In Port-au-Prince there is a small university, the State University of Haiti. Many students attend universities in Europe and North America.

Health and welfare. Haiti has the highest rate of infant mortality in the Americas. The diet is notoriously insufficient, and infectious diseases abound because of improper shelter, unsafe water, and unsanitary living conditions. Malaria and acquired immunodeficiency syndrome (AIDS) are recognized as diseases of national seriousness. There is a chronic shortage of health care personnel. Generally speaking, the state does not provide adequately for the basic needs of the population.

Cultural life. In contrast with economic difficulties and political instability, Haiti's cultural life displays variety and originality and shows authentic achievements in many areas. Artists have drawn from the vitality of the people and the rich folklife to create internationally recognized works of art. Port-au-Prince is the centre of cultural and intellectual life, and the nation's most important museums, libraries, and entertainment facilities are located there.

Visual arts. Haitian paintings have received attention since the 1940s, when a school of "naive" or "primitive" artists developed in Port-au-Prince and Cap-Haïtien. The works of the earlier and more famous artists are exhibited in major galleries in the United States and France. Primitive influence is also evident in such handicrafts as wood carvings and tapestries, which are manufactured in Haiti but sold throughout the Caribbean.

Music. African drum rhythms are combined with early 19th-century European dance music to create the merengue, a relatively slow, rhythmic music played by bands at public and private functions. The music of Haiti has generated original dance movements and expressions.

Literature. Haitian literature is written almost exclusively in French. Efforts are being made to establish Creole *Creole* as a literary language, however, and novels, poems, and *influence* plays have been written in Creole. Haiti has had some *in* writers of international status, including Jean Price-Mars, *literature* who evaluated the black African heritage in Haitian culture; Jacques Roumain, a brilliant poet, essayist, and novelist; Jacques-Stephen Alexis, who wrote novels and other works dealing with Haitian society; and René Depestre, noted for his poetic creations in an elegant French.

Recreation. Haiti is a country of intense poverty, and its citizens do not generally have access to many types of organized recreational activities prevalent in other countries. Nevertheless the colourful Lenten carnival—although perhaps not as elaborate as some—is widely celebrated. The only team sport of note is soccer, which draws

Hubertus Kanus—Photo Researchers

Vendors displaying their wares at the crowded Iron Market in Port-au-Prince, Haiti.

sizable crowds to matches in Port-au-Prince. Cockfighting, however, may be Haiti's most popular activity, attracting, particularly, the gambling enthusiast.

Press and broadcasting. Technical and political difficulties have severely affected publishing in Haiti. Book publishing is limited, and French publishers have taken the lead in the publication of French literature. Censorship has been frequently enforced, and many writers have emigrated to Montreal, New York City, and Paris. Several daily newspapers circulate in Haiti, most of them published in the capital. There are two television stations, one of them government-owned, and a number of radio stations whose broadcasts are received throughout the island. (C.A.G.)

For statistical data on the land and people of Haiti, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

Christopher Columbus sighted the island that now includes Haiti and the Dominican Republic on Dec. 6, 1492, and named it La Isla Española. By the end of the 16th century, most of the island's original Arawak Indian population had disappeared from conquest or warfare or by being worked to death or killed by disease. Spanish settlement was thin and restricted mainly to the eastern end of the

Arrival of the French

island; French pirates, based in Tortuga and other islands, had an almost unimpeded run of the western end. The pirates began to establish plantations there; in 1664 they founded Port-de-Paix in the northwest, and the French West India Company took possession.

The French colonial regime. In 1697, by the Treaty of Rijswijk, the western third of the island was formally ceded to France by Spain and was renamed Saint-Domingue.

Saint-Domingue's population increased greatly during the 18th century. It became the most prosperous New World colony, exporting sugar, coffee, cocoa, indigo, and cotton cultivated by African slave labour. By 1789 nearly two-thirds of France's foreign investments were based on Saint-Domingue, and in a good year its trade needed more than 700 oceangoing vessels.

Saint-Domingue had a population in 1789 of 556,000; of this, 500,000 were black slaves, 32,000 were whites, and 24,000 were free blacks. On Aug. 24, 1791, stimulated by the French Revolution, the slaves rose in rebellion. In order to maintain the island as a French possession, slavery was abolished in 1794. In 1795, by the Treaty of Basel, Spain ceded the rest of the island to France, but war in Europe precluded the actual transfer of possession.

Toussaint-Louverture

In May 1801 Toussaint-Louverture, a former slave, became governor-general, but he would not declare the colony independent. Napoleon sent his brother-in-law, General Charles Leclerc, with an experienced force, including several mulatto officers in exile from Saint-Domingue, to restore the old regime. After several months of struggle against Leclerc's forces, in May 1802 Toussaint came to terms with the French expedition. The French, however, broke the arrangement and imprisoned him in France. He died on April 7, 1803.

In the face of a rumour that Napoleon intended to restore slavery in Saint-Domingue as he had done in other French possessions, Jean-Jacques Dessalines and Henry Christophe led a black army against the French in 1802. The French commander and a large part of his army were defeated, and on Nov. 9, 1803, the remnant of the French expedition, under the Viscount de Rochambeau, surrendered. Under the armistice signed on November 18, the French withdrew, but they maintained a presence in the eastern part of the island until 1809.

Independent Haiti (1804–1957). On Jan. 1, 1804, the entire island was declared independent under its original Arawak name of Haiti. The war with France had utterly laid waste the country and destroyed the economy. In October 1804 Dessalines assumed the title of Emperor Jacques I; on Oct. 17, 1806, he was killed while trying to put down a mulatto revolt, and Henry Christophe took control of his kingdom. Civil war broke out between Christophe (later Henry I) in the north and Alexandre Sabès Pétion, based at Port-au-Prince in the south. In

1809, with British help, Spanish rule was restored in the eastern part of the island (Santo Domingo).

Christophe managed to improve the country's economy, but he had to force peasants to work on the plantations. He built a spectacular palace, Sans Souci, as well as an imposing fortress, the Citadelle Laferrière, in the hills to the south of Cap-Haïtien, where, with mutinous soldiers almost at his door, he committed suicide in 1820.

Jean-Pierre Boyer, who had succeeded to the presidency of the mulatto-led south on Pétion's death in 1818, became president of the entire country after Christophe's death. In 1822 he invaded and conquered Santo Domingo, which had declared itself independent from Spain the previous year and was now engaged in fighting the Spaniards. Boyer abolished slavery and confiscated church property in Santo Domingo; it was not until 1844 that the Haitians were expelled from Santo Domingo by a popular uprising.

Haitian independence was recognized by France in 1825, in return for an indemnity of nearly 100 million francs, to be paid at an annual rate until 1887. Britain recognized the state in 1833, and the United States in 1862, after the secession of the Southern slave states.

Boyer was overthrown in 1843. Between then and 1915 a succession of 20 rulers followed, 16 of whom were overthrown by revolution or were assassinated. Faustin-Élie Soulouque, who became president in 1847 and emperor for life in 1849, was extremely repressive. He turned on his mulatto sponsors, and his regime was in some ways a return to power of the black party. He tried unsuccessfully to annex the Dominican Republic (formerly Santo Domingo) and was overthrown in 1859 by one of his generals, Fabre Geffrard. Geffrard tried to reduce repression, encouraged educated mulattoes to join his government, and established Haitian respectability abroad. The 1890s saw an increase in U.S. attempts to gain military and commercial privileges in Haiti. In 1905 the United States took Haiti's customs into receivership, and, before World War I, U.S. business interests had gained a secure financial foothold and valuable concessions.

Fabre Geffrard

U.S. occupation (1915–34). From 1915 to 1934 Haiti was occupied by U.S. marines. The United States claimed legal justification on the grounds of humanitarian intervention and under the Monroe Doctrine. Many Haitians believed that the marines had really come to protect U.S. investments in the country and to establish a base to protect the approaches to the Panama Canal. Haiti signed a treaty with the United States—originally for 10 years, but it lasted until 1934—establishing U.S. financial and political domination. In 1918, in an election supervised by the marines, a new constitution was introduced that permitted foreigners to own land in Haiti.

One effect of the marine occupation was the nominal reestablishment of the mulatto elite in control of the government. Many Haitians resented the occupation, which they believed excluded them from public office and subjected them daily to racist indignities at the hands of the marines. The marines revived an old law of Christophe's time, which enabled them to employ forced labour on the roads. This resulted in a revolt of *cacos* (guerrillas), which was suppressed. The program of public works undertaken by the marines in health clinics, sewage, and roads hardly satisfied the Haitians, who felt the effort inadequate.

In October 1930 a national assembly, the first since 1918, was elected. Controlled by nationalists, it in turn elected as president Sténio Joseph Vincent. In August 1934 the U.S. president, Franklin D. Roosevelt, withdrew the marines; but direct U.S. fiscal control continued until 1941, and indirect control continued until 1947.

Presidential regimes (1934–57). In 1935 a plebiscite extended Vincent's term to 1941 and amended the constitution so that future presidents would be elected by popular vote.

In October 1937, troops and police from the Dominican Republic, with popular support, massacred thousands of Haitian labourers living near the border. The following year the Dominican government agreed to pay $3.4 million in compensation to relatives of those slain, but only part was actually paid. The enmity between the two countries had long historical roots. The Dominicans,

with their Spanish culture and largely European ancestry, disdained black Haitian labourers, though the Dominican economy depended on cheap Haitian labour.

In 1946 Haitians forced the ouster of Élie Lescot, who had succeeded Vincent in 1941. Thereafter, an alternating series of military takeovers and thwarted presidencies followed. Few rulers lasted more than a few years and most considerably less.

The Duvalier years. In September 1957 François Duvalier (called "Papa Doc")—a physician with an interest in voodoo—was elected president. He promised to end domination by the mulatto elite and to bring political and economic power to the black masses. Violence continued, and, after a coup attempt in July 1958, Duvalier organized a paramilitary group—the so-called Tontons Macoutes ("Bogeymen")—to terrorize the population. In 1964 Duvalier had himself elected president for life.

During the Duvalier regime, Haiti experienced increasing international isolation, renewed friction with the Dominican Republic, and an exodus of Haitian professionals. The regime was characterized by corruption and human rights abuses, but a personality cult developed around Duvalier, and some sectors of society, including a small upwardly mobile black middle class, strongly supported him.

Near the end of his life, Duvalier faced a contracting economy, withdrawal of most U.S. aid, and a decline in tourism; in response he relaxed some of the severe repression and terror that had characterized his early regime. Before his death in 1971, he designated his son, Jean-Claude, aged 19 and nicknamed "Baby Doc" by the foreign media, to succeed him as president for life. The regime of Jean-Claude Duvalier sought international respectability. Repression diminished, and tourism, U.S. aid, and the economy revived somewhat.

Nevertheless, by the mid-1980s the Tontons Macoutes numbered some 15,000; yet even they failed to silence a series of nationwide demonstrations against high unemployment, poor living conditions, and the lack of political freedom. In February 1986 Duvalier, with U.S. assistance, fled Haiti for France.

Two public health scares—an outbreak of swine fever that necessitated the extermination of Haiti's pig population and the identification and spread of HIV/AIDS in the country—combined with ongoing political unrest effectively ended tourism in the 1980s.

Democratic aspirations. After Duvalier's departure, a five-member civilian-military council led by Lieutenant General Henri Namphy took charge, promising elections and democratic reforms. However, attempts at democratic process were unsuccessful. Two regimes, those of Leslie Manigat and Lieutenant General Prosper Avril, lasted less than a year.

On December 16, 1990, Jean-Bertrand Aristide, a leftist Roman Catholic priest, won the presidency by a landslide in what were widely reported to be the first free elections in Haiti's history. However, Aristide's reformist policies alienated the elite, and, after he had been in office less than eight months, he, too, was deposed. Tens of thousands of Haitians subsequently attempted to reach the U.S. state of Florida by boat, but most were repatriated.

In September 1994 some 20,000 U.S. troops occupied the country, and a month later Aristide returned and dismantled the Haitian military. He was pressed to attempt free-market reforms, but Haitian farmers struggled to compete with cheaper imported foodstuffs.

Elections in 1995 brought René Préval, an associate of Aristide, to power for a term, but in questionable elections held in 2000 Aristide again claimed the presidency. The election results brought international aid sanctions that further impoverished an already desperate population. Open opposition to Aristide's rule broke out in 2003. By early 2004, rebel insurgents had surrounded the capital, and, having lost U.S. and French support, Aristide again went into exile.   (C.L.R.J./M.J.MacL./Ed.)

For later developments in the history of Haiti, see the BRITANNICA BOOK OF THE YEAR.

Jamaica

Jamaica, a parliamentary state within the Commonwealth, is the third largest island in the Caribbean Sea after Cuba and Hispaniola. With an area of 4,244 square miles (10,991 square kilometres), Jamaica is about 146 miles (235 kilometres) long and varies between 22 and 51 miles wide. It is situated some 100 miles due west of Haiti, 90 miles south of Cuba, and 390 miles northeast of Cape Gracias a Dios, Nicaragua, the nearest point on the American continent. The national capital is Kingston.

Christopher Columbus, who first sighted the island in 1494, called it Santiago, but the original Arawak (Taino) name of Jamaica, or Xaymaca, has persisted. Columbus considered it to be "the fairest isle that eyes have beheld," and many travelers still regard it as one of the most beautiful islands in the Caribbean.

Agriculture, the largest single employer of labour, is a principal contributor to the national income, together with industry—notably bauxite mining—and tourism. Jamaica has made great strides in economic development since its independence in 1962. The national motto, "Out of many, one people," describes a multiethnic society.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* In general, the topography consists of coastal plains encircling an island that is bisected from east to west along its length by mountains and plateaus. The mountains form the chief physical feature. Almost half of Jamaica's surface is more than 1,000 feet above sea level. The chief range rises in the east to Blue Mountain Peak at 7,402 feet (2,256 metres) and then loses altitude as it sweeps westward. The mountains contribute to the great diversity of scenery for which the island is famous, ranging from the stunted, elfin forests of the highest peaks to the dry, sandy, cactus-growing areas of the south. There are rain forests in the highlands and flat, alluvial plains located chiefly on the south side of the island. The rolling limestone hills and plateaus in the central and western areas include the unusual, trackless karst (a limestone region broken by ridges, depressions, and caverns) region of the Cockpit Country, covering 500 square miles.

Drainage and soils. There are numerous rivers and streams issuing from the central mountainous area, but many disappear intermittently into the sinkholes of the karst region. Few are navigable for any great distance because of their rapid descent from the mountains. Some of the larger rivers have alluvial plains in their lower valleys, and some have deltas. The 44-mile-long Black River in the west is the longest and most important river; it is navigable by small boats for about 25 miles from its mouth.

More than half of the island's surface is covered with white limestone that overlies yellow limestone, beneath which are older metamorphic rocks (compact rocks formed by heat and pressure) and igneous rocks (formed by the cooling of molten material). The upland areas are mostly covered with bare rock or soils of little depth and are very susceptible to erosion. The alluvium of the coastal plains is composed chiefly of deep loam and clay. The valley floors are covered with residual clays.

Climate. The tropical climate is influenced by the sea and is characterized by little change in seasonal temperature, although the mountains cause regional variations. Because the island lies between the subtropical high-pressure and the equatorial low-pressure belts of the Atlantic Ocean, the northeast trade winds are dominant and blow throughout the year. Along the coasts, breezes blow onshore by day and offshore at night. During the winter months, from December to March, cold winds known locally as "northers" reach the island through the wide, open trough of the North American plains.

Variations in temperature range from 90° F (32° C) on the coasts to 40° F (4° C) on the peaks. Kingston, at sea level, has an average daily maximum temperature of 88° F (31° C) and an average daily minimum of 71° F (22° C). At Stony Hill, 1,400 feet above sea level, the maximum and minimum means are 86° F (30° C) and 68° F (20° C).

Rains are seasonal, falling chiefly in October and May, although thunderstorms in the summer months, from June to September, can bring heavy showers. The average annual rainfall for the entire island is 82 inches (2,095 millimetres), but regional variations are considerable. The mountains force the trade winds to deposit more than 130 inches a year on the eastern parish of Portland, while little precipitation occurs on the hot, dry savanna lands of the southern and southwestern plains. Jamaica is susceptible to hurricanes during the summer but after 1951 it was not struck until Hurricane Allen in 1980 and Hurricane Gilbert in 1988. Earthquakes have caused serious damage only twice—in 1692 and 1907.

Plant and animal life. The richness and diversity of Jamaica's trees and plants constitute one of its chief glories, though it has changed considerably through the centuries. The island was completely forested in the 15th century, except for small agricultural clearings. The great timber trees were cut down for building purposes by the European settlers, and the plains, savannas, and mountain slopes were cleared for cultivation. Many new plants were introduced: the food plants—including sugarcane, bananas, and citrus—were almost all introduced to the island.

Jamaica has few indigenous quadrupeds. The coney, a member of the rodent family, once very numerous and prized as food before the European immigration, is now much reduced in range and number because of subsistence hunting and habitat destruction. The widespread mongoose, a small carnivore that feeds on rats and snakes, was introduced in 1872. The bat species are the most numerous of the mammals. The native crocodile may be in some danger of extinction, but this has not been confirmed. The main freshwater fish is the mountain mullet; there are four species of crayfish.

More than 200 species of birds have been recorded, including 25 endemic species, such as the streamertail hummingbird, which is the national bird. The bird population also includes species found both in the West Indies and in America and birds that migrate to Jamaica.

Settlement patterns. With the emancipation of the island's black slaves in 1838, a large proportion of the freed population—often with the aid of Nonconformist (non-Anglican) missionaries—left the large plantations. They moved to the hills where land was plentiful and created their own villages and communities. This migration laid the foundation of the present pattern of rural settlement.

Most of the cities and chief towns are located on the coastal plains, where the main commercial crops are grown. Kingston, the national capital, is located on the southeastern coast. It stands on the Liguanea Plain with the sea to the south and the St. Andrew Mountains, which form part of the ranges of the parish of St. Andrew, to the north. It is the commercial, administrative, and cultural centre of the island and the focus of its transportation services. Important centres in the interior are Spanish Town, the old capital 13 miles west of Kingston, and Mandeville, high in the Manchester mountains. Other important towns include Montego Bay, Ocho Rios, and Port Antonio on the north coast. Their fine white-sand beaches and exquisite mountain scenery make them popular tourist resorts.

The people. *Ethnic and linguistic composition.* The aboriginal Arawak Indians were exterminated by the Spanish colonists by the time the English invaded the island in 1655. The Spaniards themselves disappeared as a population element shortly afterward. With the large-scale introduction of African slaves to work the sugar estates, the English settlers were soon greatly outnumbered. Today the population consists predominantly of the black and mulatto descendants of those slaves. Small minority elements originate from the United Kingdom, India, China, Syria, Portugal, and Germany.

English is the official language, but a local creole is also widely spoken and has achieved considerable status. It is basically English in vocabulary and grammar but contains features derived from a variety of African languages, as well as from Spanish and, to a lesser degree, French. This creole is a language of value and charm and is an important communication element on the island. There is a wide spectrum of dialects, however, some quite removed from standard English.

Religion. Freedom of worship is guaranteed by Jamaica's constitution. No single religion has a majority of adherents, but more than half are in Protestant denominations. Less than 10 percent of the population attend the Anglican church, which, as the Church of England, was the established church of the country until 1870. The largest denomination is that of the Church of God. Other sizable groups include the Baptists, Seventh-day Adventists, Pentecostals, and Roman Catholics. Since the late 1970s there has been a steady increase of Evangelicalism. Smaller denominations, such as the Moravians, Disciples of Christ, Society of Friends, and United Church are important because of their social welfare work.

Nearly every Christian denomination and sect is represented, and the Jewish community is one of the oldest in the Western Hemisphere. There is a Hindu community, a Muslim mosque, and a branch of the Ethiopian Orthodox church. Some of the revivalist sects base their beliefs on Christianity, but their forms of worship differ widely from those accepted by most orthodox denominations. The central feature of the Pocomania sect, for example, is spirit possession; the Cumina sect has rituals characterized by drumming, dancing, and spirit possession.

Demographic trends. Through the centuries the popu-

lation rose steadily, despite considerable emigration. Peak growth rates came in the 1950s and '60s, resulting in an unusually large number of persons reaching their 20s in the 1980s. The youthful population is expected to reach about three million by the year 2000. Birth and death rates have both declined since the 1970s.

Migratory patterns

The pattern of migration began to take shape with the first wave of emigrants from Jamaica to Panama in the 1850s to help build a railway there. The French attempt to build a sea-level canal across the Isthmus of Panama in 1879 again drew Jamaican workers to Panama. The project failed, but the successful U.S. venture in the early 1900s to build the lake-and-lock canal accounted for another large emigration of Jamaican workers. The development of the banana industry in Central America drew still further numbers of Jamaicans, as did the need for workers in the sugar and coffee plantations of Cuba. Greater than all of the other emigrations combined was that to the United States, which began at the close of the 19th century, diminishing only after enforcement of quota regulations. The tide of emigration then turned toward Canada and, later, the United Kingdom and resulted in some 200,000 Jamaicans migrating to Britain during the period 1950–60; again immigration laws reduced the flow. Since the mid-1960s the United States and Canada have become the primary destination of Jamaican migrants.

The highly mobile character of Jamaica's population is further apparent in the high level of internal migration. The development of the bauxite and tourism industries was a significant factor in this regard. Between 1969 and 1974, for instance, some 28 percent of the population changed their parish of residence.

The economy. Jamaica's economy is essentially an open one, with heavy dependence on primary exports and on imports of manufactures and capital goods. There is active foreign economic participation, especially in the export sector (bauxite and alumina) and in tourism.

Resources. Among the minerals found on the island, bauxite, gypsum, silica sand, ceramic clays, marble, and limestone are of commercial interest. The bauxite is found in an area of about 1,000 square miles in central Jamaica; the gypsum and marble are in eastern Jamaica; clays are in the west; and limestone is found throughout the island.

Agriculture, forestry, and fisheries. Agriculture continues to be one of the main bases of the island's economy. The two major crops are sugar—with its by-products of rum and molasses—and bananas. Other important crops are citrus fruit, coffee, pimento, cocoa, tobacco, and ginger.

Forestry production is insufficient to meet the country's needs; most of the wood, cork, and paper consumed is imported. The government encourages afforestation.

Fishing is a major enterprise, which is estimated to support some 150,000 persons. The island shelf is the traditional fishing area. Mechanized boats sail about 60 miles southwest of Jamaica to Pedro Bank, while some fishermen travel 300 miles to fishing grounds.

Industry. Since 1952 mining has played an increasingly significant role in the country's economy. Bauxite mining has become the island's main mineral-industry enterprise. There is decreasing involvement of foreign companies, who have traditionally run the mines, while government involvement has increased. The production of silica sand is directed at local glass-container manufactures, while most of the gypsum is mined for export. Cement is largely used in local construction. Other mineral resources include limestone, marble, clay, peat, sand, and gravel, and, to a lesser extent, lignite, black sands containing titanium, copper, lead, zinc, and phosphates.

Manufacturing is increasingly important, both in providing employment and in satisfying the growing demand for manufactured goods. Processed foods, textiles, and metal products are the most important manufactures. Other significant categories are sugar, rum, and molasses processing, printing, chemical production, and cement and clay products. Industrial growth has been stimulated by the activities of Jamaica Promotions Ltd. (JAMPRO), a statutory body that promotes and facilitates both foreign and local investment, as well as Jamaican exports abroad.

Increasing reliance is being placed on tourism, which has

become the country's largest source of foreign exchange. The traditional attractions of Jamaica for the tourist are the pleasant climate, fine beaches, and superb scenery.

Electricity is supplied from both public and private sources, about two-thirds coming from the public sector. Privately owned generating plants supply the power needs of major industries.

Finance. Commercial banks, some of which are subsidiaries of Canadian, British, and U.S. banks, dominate the financial sector. Savings and credit services are also offered by life insurance companies, building societies, and credit unions. The central bank, called the Bank of Jamaica, founded in 1960, controls money and credit and promotes economic development. A number of development banks and special development funding institutions provide loans for industry, housing, tourism, and agriculture.

Trade. The principal exports are alumina and bauxite; sugar, bananas, coffee, and other agricultural products; and clothing. Jamaica's principal trading partners include the United States, the United Kingdom and other members of the European Community (EC), Canada, member states of the Caribbean Community, certain Latin-American countries, Japan, and some countries in eastern Europe. Jamaica enjoys preferential trading relationships with the member states of the EC under the Lomé Convention, with the United States under the Caribbean Basin Initiative, with Canada under the Caribean arrangement, and with other Caribbean states as a member of the Caribbean Community (Caricom). The Jamaican currency is maintained at a relatively stable exchange rate relative to the U.S. dollar.

Transportation. Generally, the transport systems follow the coastline or cut across the central mountains from north to south. The main roads encircle the island, loop into the plains areas, and cross the mountains at three major north-to-south crossings. Public passenger services are available outside the capital, which itself has a regular bus service. There are also taxi and limousine services.

The road system

The main line of the railway system, parts of which have existed since 1845, runs northwest from Kingston to Montego Bay via Spanish Town, May Pen, and Montpelier. The system is operated by the Jamaica Railway Corporation. There are scheduled international air services at the two major airports—the Norman Manley, on the Palisadoes in Kingston, and the Donald Sangster at Montego Bay; both are named for former prime ministers. These airports, together with another at Tinson Pen, Kingston, also handle scheduled domestic flights and air-taxi services. Port Antonio, Ocho Rios, and Negril have major public airstrips, and there are privately owned airstrips throughout the island. Kingston, Montego Bay, Ocho Rios, and Port Antonio are the principal seaports. Regular shipping services link Jamaica with the Caribbean, South and Central America, Canada, the United States, Europe, and East Asia.

Administration and social conditions. *Government.* Under the Jamaica (Constitution) Order in Council of 1962, by which the island achieved independence, the monarch of the United Kingdom is titular head of state. A Jamaican governor-general is chosen by the monarch on the advice of the prime minister. The prime minister is appointed by the leading political party from its parliamentary members. The legislature is a bicameral parliament consisting of a House of Representatives and a Senate. The House has 60 members, who are elected by universal adult suffrage. The speaker and deputy speaker are elected by the House from its members. The Senate has 21 members, who are appointed by the governor-general—13 in accordance with the advice of the prime minister and eight on the advice of the leader of the opposition party. The president and deputy president of the Senate are elected by its members. The principal policy-making body is the Cabinet, which consists of the prime minister and at least 11 other ministers, of whom at least two but not more than four must be members of the Senate. The Privy Council is limited to advising the governor-general on the exercise of the royal prerogative of mercy and on the discipline of government officials and employees.

Legislature

The island is divided into 14 parishes, two of which are amalgamated as the Kingston and St. Andrew Corporation. Local affairs in the other parishes are administered by individual parish councils whose members are elected. The chairmen of the councils are the mayors of those parish capitals that enjoy mayoral status.

Political parties
The two main political parties are the Jamaica Labour Party (JLP) and the People's National Party (PNP). General elections must be held at least once every five years. The most important trade unions are the Bustamante Industrial Trade Union (affiliated with the JLP) and the National Workers' Union (affiliated with the PNP). There are also employers' associations.

Judiciary. The legal system is based on English common law. The highest court in the Jamaican legal system is the Court of Appeals. It hears appeals from the Resident Magistrates' Court, which includes the Family Courts, the Kingston Traffic Court, Juvenile Courts, and a division of the Gun Court, and from the Supreme Court, the highest trial court.

Education. Primary education is free and in certain districts compulsory. A substantial part of the annual budget goes to the Ministry of Education. Considerable sums are devoted to the College of Agriculture, the College of Arts, Science, and Technology, the University of the West Indies (the main campus of which is at Mona, a northeastern section of Kingston), and teacher-training colleges. Education is provided by government-aided and private schools, some of which are run by religious bodies. In recent years there has been an emphasis on vocational training for school dropouts.

Health and welfare. Medical care is provided by several public hospitals, including the university hospital, and various health centres and clinics. There are also a few private hospitals. Highly successful programs of insect control and malaria eradication have been undertaken, and Jamaica participates in the hemispheric drive to increase levels of participation in immunization programs.

In the field of social development, government programs are geared toward helping persons to function as productive individuals or groups in their communities. These programs, prepared by government and private organizations, are designed to assist children, youth, women, and the community in such areas as vocational training and job placement. The government operates a compulsory National Insurance Scheme that provides retirement and other benefits and a noncontributory Social Assistance Programme to help the needy.

Much attention has been paid to housing, and there are many large development schemes in both urban and rural areas, especially in the Kingston and St. Andrew suburbs. Although the government undertakes many types of housing schemes, its chief concern is with low-income projects.

Cultural life. There is a vigorous and productive art movement in Jamaica. The works of Jamaican writers may be read in several languages. Jamaican artists have exhibited successfully abroad, and local art shows are a regular part of life. The Institute of Jamaica, an early patron and **Art promotion** promoter of the arts, sponsors exhibitions and awards. It has responsibility for the Cultural Training Centre, which includes schools of art, dance, drama, and music, as well as for the National Library, the National Gallery, and a publishing company. The institute is also the country's museums authority. The Jamaica Library Service, the Jamaica Archives, the National Library, and the University of the West Indies contribute to the promotion of the arts and culture, as do numerous commercial art galleries.

Theatre and musical groups are highly active on the island. The National Dance Company, formed in 1962, has earned international recognition. Much of the country's artistic expression finds an outlet in Festival, sponsored annually by the government as part of the independence celebrations. While the festival has many features of the traditional Caribbean type of carnival, it is much wider in scope. In addition to street dancing and parades, there are also arts and crafts exhibitions and literary, theatrical, and musical competitions.

The concern with Jamaica's cultural tradition is evident in an artistic and cultural awakening accompanied by

A cricket match at a ground near Ocho Rios, Jam. The sport is highly popular in the British West Indies.
© Berlitz from TSW—CLICK/Chicago

a keen search for roots in folk forms, which are based chiefly on the colourful, rhythmic intensity of an African heritage, with overtones of unique multiracial influences, **Folk** such as in reggae music. Folk music, stories, and dances **traditions** are systematically sought out and recorded. The important aesthetic elements in some of the revivalist cults, notably Pocomania, are recognized, and modern dance and drama employ many folk expressions.

Jamaica's beaches are perhaps the country's most highly utilized recreation facility. Cricket, however, is the most popular sport, played throughout the island and drawing large crowds to international matches held at Sabina Park. Soccer ranks next to cricket in importance.

Freedom of the press is guaranteed by the Jamaican constitution. The island has three daily newspapers, *The Daily Gleaner,* the *Jamaica Record,* and *The Star,* all published in Kingston. Numerous U.S. and other foreign newspapers and magazines are also readily available. The publicly owned Jamaica Broadcasting Corporation is the chief radio and television broadcaster. Other radio programming is provided by KLAS and Radio Jamaica Ltd.

(C.V.B.)

For statistical data on the land and people of Jamaica, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

The peopling of Jamaica seems to have begun from the islands to the east, at least as early as 5,000 BC. In about AD 600 a fresh wave of settlers, the Arawak, arrived backed by the prevailing southeasterly winds. They eventually settled throughout the island, and their economy, based on fishing and the production of corn and cassava, sustained a population of about 60,000, grouped in villages under the guidance of chieftains called caciques.

Columbus reached the island in 1494 and spent a year shipwrecked there in 1503–04. Spanish settlement began in 1509, when Juan de Esquivel founded the town of Sevilla la Nueva on the north coast; the island had by then been granted to the Columbus family by the Spanish crown, but in the years that followed it became something of a backwater, valued chiefly as a base for supplies of food and hides. In 1534 the capital was moved to Villa de la Vega (later Santiago de la Vega), known today as Spanish Town, and a substantial town developed there. The Spanish impact on the Arawak was disastrous, partic-

ularly because the latter were highly vulnerable to European diseases. By the beginning of the 17th century there were virtually no Arawak left, and the population of the island numbered about 3,000, including a small number of black slaves.

In 1655 a British expedition under Admiral William Penn and his colleague General Robert Venables captured Jamaica, and the island was slowly settled by its new masters. By 1660 the last Spaniard had been expelled, but the Spaniards' former slaves held on in the mountains, eventually forming bands called Maroons, a name probably derived from the Spanish word *cimarrón,* meaning "wild" or "untamed." The Maroons were joined by runaway slaves during the British occupation and long remained a thorn in the side of the British.

The buccaneers. Jamaica was governed by military authority until 1661, when Edward D'Oyley was appointed captain general and governor in chief with an executive council. The island soon became a chief resort of buccaneers, who frequently united the profession of merchant or planter with that of pirate or privateer. The buccaneers—who preyed on Spanish ships—operated mainly from their base at Port Royal. By their relentless attacks on Spanish Caribbean cities, they kept the Spaniards occupied at a time when Britain was unable to spare a fleet for the protection of its West Indian colonies.

British rule. By the Treaty of Madrid (1670), British title to the island was recognized, and the buccaneers were suppressed. The Royal African Company was formed in 1672 with a monopoly of the English slave trade, and from that time Jamaica became one of the greatest slave marts in the world, with a thriving smuggling trade to Spanish America. By the 18th century, Jamaica had become one of the most valuable of colonial possessions. In 1672 there were in Jamaica about 70 sugar works, 60 indigo works, and 60 cocoa works. An attempt was made in 1678 to impose royal taxes and to supersede the powers of the legislature. The privileges were restored in 1682; but not until 46 years later was the question of the revenue settled, with a compromise by which Jamaica undertook to pay £8,000 (later reduced to £6,000) per annum to the crown, provided that the laws of England were made binding in Jamaica; all additional revenues had to be voted annually by the assembly. In 1692 an earthquake destroyed most of the town of Port Royal and led to the foundation of Kingston.

Economics and government under colonial rule. A threatened invasion by the French and Spanish in 1782 was averted by the victory of the admirals George Rodney and Samuel Hood off Dominica. The last attempt at invasion was made in 1806, when the French were defeated by Admiral Sir John Duckworth. During the French war, Jamaica was at the zenith of its prosperity, with coffee rivaling sugar as an export crop and with more than 300,000 slaves at work. The abolition of the slave trade in 1807, however, raised the planters' costs, and the end of the war brought a steady drop in sugar prices.

Emancipation struck a further blow at the planters' prosperity and security. All slaves were emancipated by an act of the imperial parliament in 1833. They became free in fact, after a period of so-called apprenticeship, in 1838. Many left the plantations and moved to the hills, where their descendants live as small farmers today. The planters received compensation at the rate of £19 per slave but generally were left financially exhausted and with a scarcity of labour. The abolition in 1846 of the tariff protection of colonial produce in the British market reduced the price of sugar still further and in many cases destroyed the profits of the impoverished planter.

Dissensions among the executive, the legislature representing propertied interests, and the home government, as to the means of retrenching public expenditure, created much bitterness. Although some improvement marked the administration of Sir Charles Metcalfe and the Earl of Elgin, when Indian immigration was introduced to redress the scarcity and irregularity of labour and the railway was opened, the improvement was not permanent. Along with the collapse of the plantation system, there was widespread poverty and unemployment. All this produced a crisis in

1865 that changed the old social and economic patterns. An outbreak occurred at Morant Bay in October 1865, in which the chief magistrate of the parish and 18 other white persons were killed. The rising was suppressed under martial law, and the principal instigator, G.W. Gordon, was hanged. These severities were widely applauded in the West Indies, but indignation in England led to the recall of the governor, Edward John Eyre, and to a drastic change in the government of the island.

Before his recall, Eyre had induced the Jamaican assembly, frightened by the riots, to vote its own extinction. In its place a crown colony form of government, in which the governor wielded the only real executive or legislative power, was established by an act of the British Parliament in 1866. The new governor, Sir John Peter Grant, achieved a remarkable reorganization of the affairs of the colony. He established a constabulary on the lines of that of Ireland; reconstructed the judicial establishment, substituting stipendiary magistrates for the planters-justices; established a public medical service, a public works department, and government savings bank; improved education; and irrigated the fertile but drought-stricken plain between Spanish Town and Kingston. During his government the lucrative trade in bananas was started by Captain A.W. Baker, founder of the organization that later became the United Fruit Company. Bananas soon became a principal crop, grown for export by small farmers as well as by large estates. Many Jamaicans also found employment in the early years of the 20th century on the construction of the Panama Canal and on sugar plantations in Cuba.

On Jan. 14, 1907, a violent earthquake struck Kingston. Almost every building in the capital and in Port Royal was destroyed or seriously damaged. About 800 persons were killed and a large part of the city was burned. These disasters offered an opportunity of improving Kingston, and under Sir Sydney (Lord) Olivier the public offices were rebuilt on the finest street of the city.

Representative government was restored by stages from 1884, when nine elected members were added to the legislature. Their number was increased to 14 in 1895. Further changes were discussed from 1922 to 1926, and more vigorously after 1938, partly as a result of riots in that year. By 1938 dissatisfaction with the crown colony system, sharpened by the hardships and suffering brought on by a worldwide economic depression, erupted in serious and widespread rioting. These events resulted in the formation of the first lasting labour unions as well as of political parties linked to them. A growing demand for self-determination also became apparent. In 1944 a new constitution established a house of representatives elected by universal suffrage, in which a two-party pattern soon emerged. A modification of this constitution in 1953 gave departmental responsibilities to elected ministers but retained a nominated legislative council as an upper house with limited powers and an executive council including both officials and ministers. In 1957 the official members left the executive council, which then became a Cabinet under the chairmanship of the premier. Full internal self-government was obtained in 1959.

Jamaica was relatively little affected by World Wars I and II, though many Jamaicans served in the British armed forces overseas. After World War II the island profited greatly from help under the Colonial Development and Welfare Act and from outside sources of private capital. Colonial Development grants financed the building of the University of the West Indies, an important factor in the preparation for independence, which was established in Jamaica in 1947. Many new industrial undertakings were started, including a sugar refinery, citrus factories, and a cement factory. Development was temporarily checked in August 1951 by a severe hurricane, which devastated crops and killed about 150 people. The expansion of the tourist trade and the development of bauxite mining helped increase employment opportunities on the island.

Independence. On Jan. 3, 1958, Jamaica became a founding member of the West Indies Federation, a group of Caribbean islands that formed a unit within the Commonwealth of Nations. Norman Manley, leader of the People's National Party (PNP), became prime minister af-

ter the elections held in July 1959, but in 1960 the Labour Party under Sir Alexander Bustamante pressed for secession from the federation. A referendum in 1961 supported their views. At the general election in April 1962 the Labour Party was returned to power and Bustamante became prime minister. In May the federation was dissolved.

(J.H.Py./D.J.Bu.)

On August 6, 1962, Jamaica became independent with full dominion status within the Commonwealth. The following year it joined the International Monetary Fund (IMF), and in 1966 Elizabeth II, as queen of Jamaica, paid a state visit to the nation. In 1969 Jamaica became the 24th member of the Organization of American States.

The first general election since independence was held in 1967, but it was marred by violence between members of the opposing political parties. The Jamaica Labour Party (JLP) won 33 seats, and the PNP 20. Donald Sangster was made prime minister, but he died shortly after taking office. The labour leader Hugh Lawson Shearer subsequently became prime minister. In the 1972 election the PNP obtained its first major victory, and it chose Michael Manley, the charismatic son of Norman Manley, to head the government. Manley embarked on a number of social reforms, combating illiteracy and eliminating censorship and restrictions on civil liberties. However, economic problems undermined most of his social programs, and Jamaica's impoverished masses overwhelmed the government with strikes and protests.

During the crucial elections of 1976, the PNP and the opposition JLP engaged in virtual warfare. After the PNP won heavily, Manley attempted to strengthen ties with Cuba, perhaps because he lacked confidence in economic partnerships with the United States. In 1977 the government assumed majority ownership of the bauxite mines, which had been foreign-owned.

The continuing economic misery of much of the population and increasing political violence led to Manley's defeat in the 1980 election. The new prime minister, Edward Seaga of the JLP, contended with widespread destruction caused by a hurricane that year. In 1981 Seaga severed diplomatic ties with Cuba. Concurrently, relations with the United States improved, and Jamaica became a major recipient of U.S. aid. The economy performed well at first but quickly turned downward, despite the boost it received from low prices on oil imports. In 1986 the PNP won most local elections, perhaps signaling that the electorate disapproved of Seaga's policies, and in 1988 another devastating hurricane struck, wiping out any progress toward economic recovery. The PNP won decisive victories in the elections of February 1989, unseating Seaga and restoring Manley as prime minister.

Manley endorsed more conservative policies during his second term, working closely with the IMF and deregulating the financial sector. He retired in March 1992 and was replaced by Percival J. Patterson, who stabilized the economy through austerity measures. During the 1990s the PNP retained power, even during an economic recession, partly because the JLP split in 1995 (creating a third party, the National Democratic Movement). The PNP's electoral victory in 1997 marked the first time a Jamaican party had won three consecutive terms. In the early 21st century Jamaica remained economically and socially troubled, with slowed industrial output and a massive public debt. However, the tourist sector continued to grow, particularly in northern towns such as Ocho Rios and Montego Bay, and Jamaica seemed to be moving away from its history of interparty violence during electoral campaigns. (J.H.Py./D.J.Bu./Ed.)

For later developments in the history of Jamaica, see the BRITANNICA BOOK OF THE YEAR.

Puerto Rico

The Commonwealth of Puerto Rico is a self-governing island commonwealth of the West Indies associated with the United States. It lies approximately 50 miles (80 kilometres) east of the Dominican Republic, 40 miles west of the Virgin Islands, and 1,000 miles southeast of the U.S. state of Florida. It is situated in the Greater Antilles chain of the Caribbean Sea, with its northern shore facing the Atlantic Ocean. Puerto Rico and its adjacent islands cover an area of 3,515 square miles (9,104 square km)—slightly smaller than Jamaica.

Under Spanish authority from 1493 until 1898, Puerto Rico's lack of resources resulted in neglect and minimal investment by the Spanish. The capital city of San Juan, however, has one of the best harbours in the Caribbean,

and the Spanish built fortifications to protect this asset for their vital oceanic trade routes. When the United States acquired Puerto Rico in 1898 as a result of the Spanish-American War, it found itself in control of a poor island whose inhabitants were mostly involved in small-scale agriculture. The social system at that time was Spanish and conservative; the people were mostly rural, poor, uneducated, Roman Catholic, and resistant to change. The sudden intrusion of capitalistic ideas and values assured a high degree of social and cultural conflict.

Modern Puerto Rico is generally well-off by Latin-American standards. Beginning in the 1940s, a political coalition between the Puerto Rican leader Luis Muñoz Marín and the U.S.-appointed governor, Rexford Guy Tugwell, was "Operation forged to promote a self-help program, called "Operation Bootstrap" Bootstrap," of economic development and social welfare. In a little more than four decades, much of the territory's crushing poverty was eliminated. This was done partly through emphasis on the development of manufacturing and service industries, the latter related to an enormous growth in tourism. Improvements have been made largely with the cooperation of the United States, but relationships with that country have also become a focal point of political turmoil. Various factions have bitterly disputed the political status of the island, and, although a majority voted to retain its commonwealth relationships, strong minorities have continued to push for statehood or—at times with violence—independence.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Puerto Rico's mountainous backbone is the easternmost extension of a tightly folded and faulted ridge that extends from the Central American mainland across the northern Caribbean to the Lesser Antilles. While the highest point on the island reaches only about 4,389 feet (1,338 metres) at Mount Punta, there is a marine trough north of San Juan that plunges to more than 30,-000 feet (9,144 metres) below sea level, one of the lowest ocean depths. The great difference in crustal elevations illustrates the strong tectonic forces that have operated in geologic history to create these features. Puerto Rico still occasionally suffers from earthquakes, reflecting the ongoing geologic processes. Rectangularly shaped, the island measures, at most, only about 111 miles from east to west and a mere 40 miles from north to south. Two important islands off the east coast, Vieques and Culebra, are also parts of Puerto Rico, as is the island of Mona to the west.

Terrain Most of Puerto Rico is either mountainous or hilly terrain, with nearly a fourth of the island composed of steep slopes that inhibit agriculture and increase building costs. The highest mountain range, the Central Cordillera, with altitudes exceeding 3,000 feet, trends east–west and is located off-centre, closer to the south coast. Slopes rise abruptly from the south coast to the highest peaks and descend more gently toward the north. The Caguas Basin is the largest of several basins in the mountains that provide level land for settlements and agriculture. There is a continuous but narrow lowland along the north coast. Most people live along the coastal lowlands, and migration from the mountainous rural areas to the coastal cities continues to empty out the island's interior.

Drainage and soils. Because most of Puerto Rico's precipitation falls on the north-facing mountain slopes, the majority of the permanent rivers flow from the interior to the north coast. The river courses on the south coast are dry most of the year, carrying water only after rainfall. No river is large enough for navigation, but several north-flowing rivers have been dammed for hydroelectric power and to provide drinking and irrigation waters. Irrigation along the south coast is essential for agriculture. Some pockets of alluvial soils on the south coast have better than average fertility, but all agricultural areas need fertilizer for commercial production and most need irrigation or conservation techniques to preclude destructive erosion. Many worn-out areas in the mountains have been set aside for forest preserves.

Climate. Puerto Rico's tropical climate varies according to elevation and exposure to rain-bearing winds. Northeast trade winds bring heavy rainfall to the north coast, while the south coast is in the rain shadow of the mountains. San Juan receives 60 inches (1,524 millimetres) of rain; El Yunque Peak farther east receives 180 inches (4,572 millimetres); while Ponce on the south coast receives only 36 inches (914 millimetres). Rain falls each month of the year, but the heaviest rainfall occurs between May and December. The average daily humidity is 66 percent, which makes the 78° F (26° C) average lowland temperatures feel warmer. Highland temperatures average about 5° F less, and the annual range between the hottest and coolest months in highlands or lowlands is less than 6° F (3° C). Hurricanes occur between June and November, sometimes exacting high tolls in property damage and loss of life. The delightful climate and beautiful beaches are an important resource for tourism.

Plant and animal life. Plant life is abundant and varied. Tropical rain forest is one of the main types of natural vegetation on the north side of the island, while light precipitation on the south side restricts growth to mostly thorn and scrub vegetation. Most of the island's original vegetation has been removed through centuries Vegetation of agricultural exploitation, and planted varieties of trees, shrubs, and grasses now predominate. The scarlet- and orange-flowered royal poinciana, or flamboyant (*Delonix regia*), and the African tulip (*Spathodea campanulata*) are among the trees that dot the mountains with patches of vivid colour against the lush green background. Within the Caribbean National Forest southeast of San Juan are preserved rare species of orchids and an unusual species of small green parrot. Birds are abundant in numbers and types, but land animals are mostly confined to nonpoisonous snakes, lizards, mongooses, and the *coqui,* a frog that has become a symbol of Puerto Rico. Numerous varieties of fish abound in the surrounding waters, but edible and nonedible species mingle together, making commercial fishing more difficult.

James P. Rowan

The dense Caribbean National Forest, southeast of San Juan, P.R.

Settlement patterns. Since the 19th century the dispersed farmsteads in the hills of Puerto Rico have given way to an urban society with scattered villages in the mountains. Puerto Rico is now about 70 percent urban. Because there is an efficient network of good roads, many urban areas have merged. A virtually continuous urban area has developed from Caguas to San Juan, and along the north coast from Fajardo through San Juan to Arecibo. Ponce on the south coast and Mayagüez on the west are

other urban cores. There is hardly a place on the island that is as much as an hour's drive from a major urban area. The largest metropolitan area is that of San Juan, which includes several municipalities in addition to the city proper. Each urban centre includes modern shopping centres and other services found in comparably sized cities on the U.S. mainland. Rural villages receive piped water, electricity, and other modern amenities. The government has had a long-standing policy to upgrade rural areas with programs that provide low-cost housing and incentives to disperse factories throughout the island.

The people. *Ethnic composition.* In 1493 Columbus found the island of Borinquen (the Amerindian name for Puerto Rico) to be inhabited by Taino Indians, a subgroup of the Arawak. About 200 years later the Taino population of some 30,000 had been reduced to only 2,000. Only a few African household slaves were brought to Puerto Rico in the early years of settlement, because the plantation system was not introduced until the early 19th century. For some 300 years Spanish males constituted the largest group of immigrants. The Spanish interbred with Amerindians and Africans with little social stigma. When slavery was abolished in 1873, only about 5 percent of the population was pure African. Some Chinese, Italians, Corsicans, Lebanese, Germans, Scottish, and Irish also found their way to the island in the mid-19th century. During this time the population grew steadily, becoming racially and culturally homogenous. People from the United States arrived after 1898, and the most recent large-scale immigration was the arrival of 23,000 Cubans after Fidel Castro came to power and an almost equal number of largely job-seeking people from the Dominican Republic. Although Puerto Rico's population today is racially mixed and there is no overt racism, pure Spanish bloodlines are still socially important for the elite group.

Linguistic composition. Many English words have found their way into the Spanish of Puerto Rico, and numerous attempts at bilingual education have been made throughout the 20th century, but Puerto Rico remains predominantly Spanish-speaking.

Religion. Puerto Rico is primarily Roman Catholic in religious affiliation, a legacy of its centuries as a Spanish colony. In the 19th century the church's loyalty to Spain eroded much of its popular support. After 1898 Protestantism began to grow, and the single largest Protestant church is the Pentecostal Church of God. Puerto Rico's constitution guarantees freedom of religion.

Demographic trends. Overpopulation in Puerto Rico had become a critical problem by 1940. Health improvements as a result of the U.S. occupation had drastically reduced death rates, contributing to a population explosion that resulted in a 21-percent increase between 1930 and 1940. Because the island is relatively small and has limited physical resources, its already fragile economy and the quality of life were threatened. Birth control and mass migrations to the U.S. mainland slowed population growth beginning in the 1950s, but crowded conditions have continued to put pressure on the economy. Infant death rates have been reduced and life expectancy increased so that both figures approach U.S. standards. Birth rates, death rates, and educational achievement also compare favourably with the United States. Improved conditions have prompted a small movement from the mainland back to Puerto Rico, the rate of which has at times exceeded that of emigration.

The economy. Manufacturing and services produce about three-fourths of Puerto Rico's wealth. Before 1955, agriculture was the leading sector of the economy. Operation Bootstrap produced spectacular although not totally successful results. After the plan's initial effort to increase employment in cooperative agricultural enterprises and labour-intensive industries had failed, the government sought to bolster the infrastructure and to promote private enterprise. Low wage rates on the island, advantageous tax breaks, and government-supported start-up costs induced hundreds of manufacturing firms from the U.S. mainland to establish operations in Puerto Rico. These firms included those producing textiles, processed food, shoes, clothing, ceramics, tobacco, and wood products. Puerto

Rico's Economic Development Corporation (Fomento in Spanish) guided economic development. To extend the early success of the Bootstrap program, Fomento in the 1960s made the decision to promote petrochemicals and other high-technology industries. Income from U.S. federal agencies operating in Puerto Rico and various social welfare programs also became vitally important in maintaining an adequate standard of living. Nevertheless, the unemployment rate has been high.

Resources. Other than picturesque beaches and a tropical climate, Puerto Rico is resource-poor. Limited flat land and good soils considerably handicap agriculture. Only clay, silica sand, stone, and limestone exist in sufficient quantities to allow industries to produce goods for domestic use and export. No commercial deposits of coal, oil, or natural gas are present, and the forests have limited value. Local waters produce good game fish, but commercial tuna fleets must fish off the coast of Africa or even the Pacific coast of the Americas to bring in their haul.

Agriculture, forestry, and fishing. Once the mainstay of the economy, primary activities now employ less than 4 percent of the labour force and contribute less than 3 percent of the gross national product (GNP). Plantation sugar production was firmly entrenched by U.S. corporations, and the industry dominated employment and income until the 1940s. Sugar production has become less significant but is still important for the molasses and rum industries. Coffee, tobacco, and milk are traditional farm products, but more land is being put into new, specialized products. Pineapples and other tropical and citrus fruits, beef, pork, poultry, and eggs are produced for local and export markets. Bamboo and tropical hardwoods support a small furniture industry. Local waters supply a variety of seafood for local markets. The tuna industry is a large-scale international operation that brings its catch from faraway grounds to plants around Ponce for processing and export.

Industry. Manufacturing, largely through investment by U.S. firms, is dominated by high-technology industries such as those producing petrochemicals, electronics, machinery, chemicals, pharmaceuticals, and medical equipment. More than 2,000 manufacturing establishments operate on the island. Most industrial components must be imported and final products are exported. Puerto Rican wage rates now equal those of the United States, and the island is no longer competitive in labour-intensive industries with many other Latin-American or Asian countries. Tourism has developed into a major industry.

Finance and trade. Finance and trade are dominated by U.S. firms. More than one-third of all U.S. investment in Latin America is located in Puerto Rico. Banks, retailers and wholesalers, restaurants, insurance companies, hotels, airlines, and many other firms in trade or commerce have profitable operations on the island. Guarantees of the U.S. Constitution, ready access to New York City's credit markets, exemption from U.S. taxes on profits, and being part of the U.S. monetary system all make investment easy and profitable. Puerto Rico's most important trading partner by far is the United States. The chief exports include petroleum products, food products, and chemicals; the main imports are machinery and transport equipment, manufactured goods, and food products.

Transportation. Puerto Rico has no public railway system for passengers or freight, but modern paved roads crisscross the island and rim the coasts. Most international commerce is carried on by ocean transport. San Juan's international airport, 5 miles outside the city, handles passenger and freight traffic, and it is conveniently located to serve the industries and hotels clustered there.   (R.J.Ta.)

Administration and social conditions. *Government.* Puerto Rico's political status is officially described in its constitution as a "freely associated state" within the federal system of the United States. Puerto Ricans are U.S. citizens, and they elect a resident commissioner to the U.S. House of Representatives, who is allowed to speak but may not vote except in committees. (Thus, because they are without representation, Puerto Ricans do not pay federal taxes.) The 1952 commonwealth constitution was patterned after its U.S. counterpart, and it sets up executive, legislative, and judicial branches in a democratic

Major immigrations

Cash crops

U.S. manufacturing investment

framework. The constitution may be altered by the commonwealth so long as the articles are not in conflict with the U.S. Constitution or the legal stipulations of Puerto Rican-U.S. relations.

The governor, who is elected by direct popular vote to a four-year term, heads the executive branch. The legislature comprises the Senate and the House of Representatives, whose members are elected for four years. There are eight senatorial districts (with two senators each) and 40 representative districts, and in addition 11 senators and 11 representatives are elected at large. A formula assures proportional representation of minority parties.

Customs taxes on foreign goods imported into Puerto Rico and excise taxes on goods sold in the United States are collected by the federal treasury. Relations between Puerto Rico and the United States are defined in the Puerto Rico-Federal Relations Act, which retains many provisions of the Foraker (1900) and the Jones (1917) acts. Local government—excluding San Juan, which has a city-management rule—is run by a popularly elected mayor and council.

Elections are held every four years, supervised by an electoral board comprising representatives from majority and minority parties. There are four principal registered parties: the New Progressive Party, the Popular Democratic Party, the Puerto Rican Independence Party, and the Puerto Rican Socialist Party. The two leading parties are the pro-statehood New Progressive Party, and the Popular Democratic Party, which supports the continuation of commonwealth status. The Puerto Rican Independence Party and the Puerto Rican Socialist Party advocate independence.

Justice. Puerto Rico has a unified court system, which is administered by the island's Supreme Court, whose justices are appointed by the governor with the advice and consent of the commonwealth Senate. A federal district court has jurisdiction over the application of federal laws in Puerto Rico, and appeals may be carried to the U.S. Supreme Court in Washington, D.C.

Education. Puerto Rico is deeply committed to the expansion of public education. The island invests about 7 percent of its GNP in education. Literacy has increased to about 90 percent with most children completing at least eight years of education; schooling is compulsory for children between six and 16 years of age. A serious problem is the high dropout rate. Vocational technical education has been stressed to combat the high rate of unemployment. The main institution of higher learning—the University of Puerto Rico, whose Rio Piedras campus was founded in 1903—has three campuses and provides programs ranging from agricultural science to medicine. There are also several private universities.

Health and welfare. Urban clinics and rural health centres have been created to provide basic medical and health care. Health conditions are almost up to the standards of the U.S. states. The U.S. Medicare and Medicaid programs have contributed to improving health quality, as have various other social programs.

Puerto Rico has made impressive strides in meeting its housing shortage, although the pressures continue due to population growth. The Urban Renewal and Housing Corporation is in charge of broad and diversified housing programs, with concentration on low-income projects.

Cultural life. Puerto Rican cultural life is a blend of modern North American and traditional Latin and African forms. Dance, music, art, literature, and sports all display influences from the United States and Caribbean neighbours. The heritage from Amerindians is minimal because their numbers were small and they were quickly wiped out by the colonizers. African influences are evident in food, dress, music, and art. Music festivals, good museums in Ponce and San Juan, and theatre performances encourage "Hispanidad," or Spanish customs. The preservation of its Latin heritage, while at the same time embracing U.S. economic and social modernness, has become a Puerto Rican dilemma that often surfaces in political debate. The idealized folk hero of Puerto Rico is the *jíbaro*, the rugged, independent hill farmer of yore, who has a status similar to the gaucho of Argentina in local song and story.

Literature and theatre. Contemporary poets, novelists, short-story writers, and essayists keep alive the traditions of such 19th-century forerunners as the novelist Alejandro Tapia, the essayist Eugenio María de Hostos, and the poet José Gautier Benítez. New playwrights and artists have also received considerable encouragement from the Institute of Culture.

Music. Nineteenth-century composers included Manuel Tavárez and Juan Morel Campos, both known for their dance melodies. The popular 20th-century songwriter Rafael Hernández is still revered, and singers such as Antonio Paoli, in the early part of the 20th century, and José Feliciano achieved international reputations. The noted Spanish cellist Pablo Casals, whose mother was Puerto Rican, moved to the island in 1957 and founded the world-famous music festival that bears his name and that attracts international performers to San Juan every June. Latin and African folk music is preserved by many groups.

Recreation. Typical of Latin-American nations, Puerto Rico celebrates numerous religious holidays with colourful festivals, but as a U.S. territory it also observes many of the secular holidays of the mainland. Baseball is Puerto Rico's national sport, and the island's professional league is a testing ground for U.S. major league prospects. Basketball is also popular among the people, and the usual Caribbean activities are broadly available to tourists. Cockfighting is a popular gambling activity.

Press and broadcasting. The commonwealth has a free press that may be independent or politically partial. Both local and major U.S. newspapers are widely available. The major dailies published on the island include *El vocero de Puerto Rico* ("The voice of Puerto Rico") and *El Nuevo Día* ("The new day"). Radio and television are well established, the first local radio broadcast dating from 1923 and television from 1954. Both commercial and public channels offer programming comparable to that of the U.S. mainland.   (A.M.-C./R.J.Ta.)

For statistical data on the land and people of Puerto Rico, see the *Britannica World Data* section of the BRITANNICA BOOK OF THE YEAR.

HISTORY

The first inhabitants of Puerto Rico, probably from the Florida Peninsula, reached the island more than 1,000 years before the arrival of the Spanish. These primitive inhabitants collected food from the seashore and wild fruit from the land. By the year AD 1000 Arawak Indians, who developed the Taino culture, had arrived by way of the Lesser Antilles from the tropical forests of South America. The Arawak, living in small villages, were organized in clans and led by a cacique, or chief. They were a peaceful people who, with a limited knowledge of agriculture, lived on such domesticated tropical crops as pineapples, cassava, and sweet potatoes supplemented by seafood. Anthropologists estimate their numbers to have been between 20,000 and 50,000. On a fertile island the Arawak lived an easy life disturbed only by occasional visits from their Carib neighbours on the islands to the south and east. At the time of discovery, Carib Indians occupied most of the Lesser Antilles, the Virgin Islands, and Vieques Island.

In 1493 Christopher Columbus left Spain on his second voyage to the Indies with an elaborate expedition of 17 ships and about 1,500 men. At the island of Guadeloupe the Spaniards rescued several Arawak Indians who had been taken from Boriquén, the Indian name for Puerto Rico, by the Caribs. Columbus agreed to return them to their island, and on Nov. 19, 1493, the expedition anchored in a bay on the west coast of Puerto Rico. Columbus formally took possession of the island in the name of Ferdinand and Isabella, the rulers of Spain, and named it San Juan Bautista. Two days were spent on the island before the ships moved westward to Hispaniola, where the first settlement in the New World was established.

Spanish rule. *Early settlement.* For 15 years the island was neglected except for an occasional visit by a ship putting in for supplies. In 1508 Juan Ponce de León, who previously had accompanied Columbus, was granted permission to explore San Juan Bautista in recognition of his valuable colonizing efforts in eastern Hispaniola. On the

Columbus' visit to Puerto Rico

north coast, Ponce de León found a well-protected bay that could offer safe harbour for a large number of sailing vessels, and he founded the first town, Caparra, the site of the first mining and agricultural efforts. The harbour was named Puerto Rico because of its obvious excellent potentialities. In this area was located the most important settlement on the island; through time and common use the port became known as San Juan, while the name Puerto Rico came to be applied to the whole island.

The peaceful and friendly relations with the Arawak did not last long. The Spaniards expected the Indians to acknowledge the sovereignty of the king of Spain by payment of gold tribute. The Indians were to be instructed in Christian ways. In return for this education, which was rarely given, the Arawak were expected to work and supply either more gold or provisions of food. In 1511 the Indians rebelled against the Spanish, who with their superior arms rapidly subjugated them.

Placer mining of gold was continued by Indians brought from other islands and by blacks brought from Africa by some of the early traders. After the 1530s, however, gold production markedly declined with dwindling Indian labour, and the Spanish colonists, with slaves from Africa, turned to agriculture.

Puerto Rico, however, did not prosper economically. Carib Indians from neighbouring islands made frequent raids, carrying off food and slaves and destroying property. The colony continued to lead a precarious existence, ravaged by plagues and plundered by French, British, and Dutch pirates. Repeatedly during the mid-16th century the French burned and sacked San Germán, the second community to be established on the island. People began to leave the island at every opportunity.

In the second half of the 16th century Spain, recognizing the strategic importance of Puerto Rico, undertook to convert San Juan into a military outpost. The fortress El Morro, built with the financial subsidy from the Mexican mines, was well constructed and perfectly located to dominate the narrow entrance to the harbour. Later, a stronger and larger fortress was built to the east and on the Atlantic side of the city. In the early 17th century the city was surrounded by a stone wall, 25 feet high and 18 feet thick, two parts of which still stand. These defenses made San Juan almost impregnable.

Sir Francis Drake attacked the town in 1595 but failed to gain the harbour. Three years later George Clifford, 3rd Earl of Cumberland, had complete military success but was forced to abandon his conquest owing to an outbreak of plague among his troops. In 1625 a Dutchman, Bowdoin Hendrik, sailed into the harbour, captured and burned the town, but failed to subdue El Morro.

San Juan, as the most exposed military outpost guarding the heart of Spain's New World empire, received political and economic attention from the mother country. The rural inhabitants of the interior of the island, however, were ignored by Spain and scorned by the presidial residents of San Juan. As the French, English, Danish, and Dutch fought over and settled the Lesser Antilles during the 17th and 18th centuries, rural Puerto Ricans, ignoring the edicts of Spain, found profit in clandestine trade. Ginger, hides, sugar, tobacco, and cattle from the island were in great demand, and while the colonial authorities of San Juan rarely ventured out of their walled defenses for fear of the reprisals of the buccaneers, the rural settlers prospered in a modest way through contacts with the non-Spanish European traders. No large plantations were established, and the farmer, with little help, cultivated his own land. Contrary to the fears of Spain, this contact with foreigners did not corrupt the islanders, who remained loyal and were willing to participate in aggressive expeditions.

Liberal reforms. In 1797 the British general Sir Ralph Abercromby, who had captured Trinidad, unsuccessfully attacked Puerto Rico. The British considered the island— a centre of clandestine trade and of operations for quasi-piratical expeditions and a refuge for runaway slaves—a weak link in the chain of defense of the Spanish empire. The failure of Abercromby was due in part to the important economic and administrative changes in the Spanish colonial empire that were carried out in the latter half of

the 18th century by representatives of the Bourbon rulers of Spain. In the case of Puerto Rico it was hoped that the island might become an economic asset rather than a financial drain on the Spanish crown. Trade relations between the island and Spain were liberalized, agricultural production was stimulated, and the island as a whole was integrated into the system of military defense.

The liberal reforms of the enlightened despotism of the Spanish Bourbons coincided with and encouraged rapid population growth, introduction of new products, and the beginning of commercial agriculture. Population was estimated in 1765 at 45,000, in 1775 at 70,250, in 1787 at 103,051, and in 1800 at 155,426. By the end of the 18th century there were 34 towns on the island. Immigrants from the Canary Islands, French settlers from Louisiana or Haiti, and Spaniards from Santo Domingo, which had been turned over to Napoleon, accounted in part for the increase in population. These newcomers brought with them new ideas and methods of producing marketable crops. Coffee, introduced into the island in 1736, became an important export item by 1776. Sugar production, which had always been small, was undertaken on a large scale by augmented slave labour. From 1765 to 1800 the slave population increased from 5,037 to 13,333.

When Napoleon invaded Spain and placed his brother Joseph Bonaparte on the Spanish throne (1808), the colonies of South and Central America asserted their right to govern themselves in the name of the imprisoned Bourbon king, Ferdinand VII. This claim to temporary self-rule eventually evolved into a revolutionary movement for independence. In Puerto Rico, however, for various reasons, the sequence of events and their results were different. The communities of the interior of Puerto Rico, with one exception, offered little objection to the strict rules of Spain's mercantilist policy, which for many decades had ceased to have effect on them. Most of the residents of San Juan, on the other hand, dependent upon administrative and military positions, were most willing to follow the orders of the central government of Spain.

As the revolutions progressed on the southern and central mainlands, loyal Spaniards reluctant to leave the colonies found refuge in Puerto Rico. In recognition of its loyalty and in a belated move to liberalize an outmoded colonial system, the Spanish government granted Puerto Rico in 1815 ample economic liberties. The island was opened to all non-Spanish Catholics, the ports were permitted to trade with non-Spanish countries, and free land was granted to the new settlers. After 1830 Puerto Rico gradually developed into a plantation economy based on three main crops: sugar, coffee, and tobacco. Sugar and molasses, sold for the most part in the U.S. market, provided an important source of income for the Spanish government. Foreign settlers contributed to economic development, though the Spanish element attempted to maintain a tight monopoly.

Economic and political development. By the end of the 19th century the population had increased to nearly one million, and the value of foreign trade had increased considerably. By 1899 the United States was buying almost two-thirds of Puerto Rican sugar production. The area devoted to sugar had been slowly expanding. Coffee, in the late 19th century, provided the principal source of income for the island.

Political development in Puerto Rico during the 19th century was characterized by periods of liberal advance counteracted by long periods of conservative reaction. In part this was due to the changes occurring in the Spanish government, and in part due to the antiquated Spanish colonial administrative policy. During the first half of the 19th century, two short periods of relative political freedom were enjoyed. From 1809 to 1814 and from 1820 to 1823 Puerto Rico was declared an integral part of Spain with the right to elect representatives to the Spanish Cortes, or parliament. Ramón Power y Giralt, an able liberal, was selected during the first period and succeeded in revoking the absolute powers of the island's colonial governor. In the latter period Demetrio O'Daly secured the separation of the military authority from the colonial administrator. Freedom of the press was also permitted.

The fortification of San Juan

The British attack on Puerto Rico

U.S. sugar market

On each occasion moderate colonial rule was thwarted by the return of royal absolutism in Spain.

In 1837, when a fairly permanent constitutional monarchy was established in Spain, Puerto Rico failed to benefit because it was argued that the colonies were not true Spanish provinces and therefore should be governed by special laws. For more than 30 years Puerto Rico waited for special legislation to ease the despotic rule of military colonial governors. During this waiting period political thought in the island began to crystallize. A liberal current of opinion requested assimilation into the Spanish government and permission to be represented in and governed by the Cortes. A bloc of conservative opinion strongly approved of the status quo. A small third group advocated complete independence.

Movements toward self-government and independence. A local commission was elected in 1865 to draw up a report on the basis of which a governmental reform might be carried out. The majority report, which declared that the abolition of slavery was the sine qua non of any political reform, provoked a shocked reaction among the island and peninsular conservatives. The alarmed colonial government took steps to curtail what was feared to be a growing movement of rebellion. Some of the more outspoken and respected islanders were ordered to be arrested and sent to Spain for trial. Thus provoked, a small group of radicals committed to independence attempted an uprising, for which, however, inadequate preparation was made. El Grito de Lares, the abortive revolt of Sept. 23, 1868, brought forth severe reprisals on all island liberals. Though separatist elements joined the Cubans who were struggling for independence, they were unable to challenge Spanish power effectively. However, the abdication of Queen Isabella II of Spain was forced by a republican government that pardoned all political prisoners. The first Spanish republic extended to Puerto Rico its third period of constitutional government, 1868–74, during which slavery was abolished.

During the 1880s a movement for political self-government under Spain led by Román Baldorioty de Castro replaced the sentiment in favour of integrating Puerto Rico into the Spanish government. Again liberal political movement, this time autonomy, was denounced as disloyal and was violently suppressed in 1887. Such treatment only served to solidify the movement for local self-government, and in 1897 the Autonomy Party, through cooperation with the Liberal Party in Spain, achieved its objective. The autonomous government granted was parliamentary in form but retained the governor-general as a representative of the Spanish king. He was empowered to disband the insular parliament and suspend civil rights. The two-chamber parliament was empowered to legislate for the island, create and control an insular tariff, and levy local taxes.

The Spanish-American War. The Spanish-American War (1898) prevented the islanders from putting into effect the new government. In May 1898 Admiral W.T. Sampson bombarded San Juan for a short time without serious results. Facing token military resistance and with general popular acceptance, General Nelson A. Miles landed a U.S. force of about 3,500 men in July, and, after a short campaign, hostilities were ended on August 12.

Under the United States. *Early years.* On Oct. 18, 1898, the island was turned over to the U.S forces, and General John R. Brooke became military governor. Puerto Rico was ceded to the United States by the Treaty of Paris, signed Dec. 10, 1898 (ratified by the U.S. Senate Feb. 6, 1899). In the work of policing the country, in the accompanying tasks of sanitation, construction of highways and other public works, accounting for the expenditure of public funds, and establishing a system of public education, the military control that lasted until May 1, 1900, proved effective in bridging the period of transfer from the control of Spain to the system under U.S. civil government. The U.S. military, however, ruled with little regard for political sensitivities. The U.S. Congress passed the Foraker Act, under which civil government was instituted in May 1900. Under this act the United States exercised the controlling power, a condition that proved distasteful to many Puerto

Ricans; the organic law was subsequently amended to give a wider native participation in the government. The Olmsted Act, approved by Congress on July 15, 1909, placed the supervision of Puerto Rican affairs in the jurisdiction of an executive department to be designated by the president. The people, however, demanded a larger measure of local control. The majority also asked for U.S. citizenship and many other changes. As a result, Congress passed a new organic act (the Jones Act), which came into effect on March 2, 1917. Under its terms Puerto Rico became a territory of the United States "organized but unincorporated," and citizenship of the United States was conferred collectively on Puerto Ricans, allowing the right to retain the old status if preferred. Only 288 persons declared in favour of the latter. The local civil government, however, even with modifications, fell far short of the measure of self-government that Puerto Ricans expected in light of the democratic tradition of the United States. Key officials, including the governor, were presidential appointees and thus beyond local control.

In spite of the legal limitations on political autonomy, a climate of freedom was slowly developed as a result of the change of sovereignty. At first this new order was sometimes mistrusted, resented, and misunderstood, but in the long run it was recognized as beneficial and assimilated by the islanders. For example, the separation of church from state, resulting in open competition for religious adherence, demonstrated the new climate in a practical way; government programs that dealt directly with the vital needs of the people for education, health and sanitation, and regulation of working conditions all reflected a change designed to remedy centuries of neglect.

Economic and social changes. Early U.S. governors were mainly preoccupied with Americanizing Puerto Rican institutions, language, and political habits but had no clear policy on the island's eventual political status. This approach created strong resistance from many native leaders led by Luis Muñoz Rivera, who had fought for autonomy under Spain. The economic reorientation of the island as a result of the change in sovereignty had almost an immediate and profound effect on all aspects of life. Included within the U.S. tariff walls, Puerto Rican agricultural products, particularly sugar, had a ready market. Aided by the adoption of U.S. currency and by unobstructed financial movement, Puerto Rico experienced within a short period a large capital investment that revolutionized the production of sugar. A sevenfold expansion in acreage between 1899 and 1939, new disease-resistant plants, rapid-transportation facilities, large and efficient cane-grinding mills, and complete corporate management within a generation converted the economy of the island into one in which 75 percent of the population directly or indirectly was dependent upon sugar. The population increased from about 950,000 in 1899 to more than 1,540,-000 in 1930. Glaring inequalities of wealth contributed to sharpened social and political tensions.

The island was forced to import much of its food. Coffee was neglected at a time when weather conditions and transportation problems dictated financial and government aid. Only tobacco production experienced growth, which failed to be sustained after the 1920s when U.S. smokers shifted from cigars to cigarettes.

The shock of these economic changes might have been absorbed in spite of the island's limited resources if at the same time Puerto Rico had not been undergoing a severe social change as a result of the application of modern sanitation means and medical knowledge to a people with a very high death rate. The population was threatening to double its number in two generations. The two counterpressures—expansion of corporate control over the limited productive land and increasing population pressure—reached an explosive stage when the economic depression occupied the attention of government officials in the United States. Recurring hurricanes joined with declining exports to aggravate the economic distress of the island.

Political development. With one exception political parties that had developed since the change in sovereignty had centred their attention on modifications in the political relations between the island and the U.S. federal gov-

Margin notes:

Reprisals against island liberals

The Olmsted Act

Increased sugar production

ernment. The Republican Party limited its program to a plea for statehood for the island. The Union Party worked for greater autonomy. In the 1920s the Nationalist Party rose to affirm the ideal of immediate independence. The one exception was the pro-U.S. Socialist Party, led by the highly respected labour leader Santiago Iglesias. This party had expressed since its foundation a concern for the plight of the labouring classes of the island. Nevertheless, its effectiveness had been hampered by insufficient popular support, due primarily to the concentration of attention upon the issue of the political status of the island.

Effects of the New Deal policies on Puerto Rico

In the mid-1930s, with President Franklin D. Roosevelt's New Deal policies radically enlarging the previously accepted concept of the function of government, Puerto Rico was not neglected. More important than the much-needed temporary relief were the steps taken by the Puerto Rican Reconstruction Administration (PRRA), designed to readjust the distribution of economic power on the island. A restrictive quota was placed over sugar production. Legal procedures were initiated to enforce a long-neglected law limiting corporate holdings to 500 acres. Thus the process of increasing the sugar acreage was to be reversed, and Puerto Ricans were to be returned to their small farms.

This radical program provoked the open opposition of the sugar interests, locally vocal through the Republican Party. The Socialists accepted the program in a tacit fashion. Their reluctance was due to the fact that the young radical wing of the heirs of the Autonomy Party, led by Luis Muñoz Marín, the son of Luis Muñoz Rivera, was recognized in Washington and on the island as the local political proponent of the economic reform.

The success of the New Deal measures was jeopardized by two unconnected factors. Unforeseen administrative and financial problems forced a curtailment of the objectives of the PRRA. No longer was a complete readjustment of the island's economic structure possible; the PRRA took on a more temporary or experimental nature. The second factor was the interjection of the status issue on the political scene by the U.S. government in answer to Nationalist violence. Taking the form of a vindictive offer of independence under adverse economic conditions, the proposal served to realign again the political parties into pro- and anti-independence groups.

Ascendency of Muñoz Marín

The incipient political movement for economic reform originally fostered by the New Deal and temporarily sidetracked was surprisingly successful in the election of 1940. This new political movement took the form of a political party, led by Muñoz Marín, called the Popular Democratic Party (PPD). Organized to improve the conditions of the lower classes, particularly the hardworking *jíbaro* of the mountainous interior, the new party's platform was summarized by the slogan "Bread, land, and liberty." The island electorate had agreed that the political status was not in issue and that economic and social problems took precedence. Tenuous control over the island legislature and a new-style colonial governor, Rexford Guy Tugwell, allowed the PPD to initiate such economic reforms as redistribution of land, enforcement of minimum wage and hour laws, an enforced progressive income tax law, and the establishment of an economic development program. In recognition of partial fulfillment of its announced aims the PPD was overwhelmingly backed by the island electorate in 1944. In 1946 President Harry S. Truman named Jesús T. Piñero, a Puerto Rican, as governor, the first Puerto Rican to occupy that post. In 1947 the U.S. Congress amended the organic act of Puerto Rico to permit election of governors by popular vote. Muñoz Marín was elected Nov. 2, 1948, and took office in January 1949.

For more than a generation the PPD, led by Muñoz Marín, governed Puerto Rico. Muñoz served for four terms as governor and was followed by his able administrative assistant Roberto Sánchez Vilella. In 1968, because of a split in its ranks, the PPD lost control of the lower house of the legislature and also relinquished the office of the governor to the pro-statehood New Progressive Party (PNP), led by the industrialist Luis A. Ferre, who became the governor of Puerto Rico.

From 1948 to 1968, under the PPD, Puerto Rico experienced a major economic change. An economy based on agriculture was transformed into one based on industrial production. Favourable tax laws encouraged the establishment of new industries such as those for electronic and pharmaceutical products. Workers left the sugarcane fields and the coffee haciendas and moved into the coastal cities where wages, working conditions, and social services were better. Many also migrated to the large metropolitan centres in the mainland United States.

Establishment of the commonwealth. The PPD also modified the political relationship with the United States. Responding to an offer made in 1950 by the U.S. Congress, the Puerto Rican people participated in a Constitutional Assembly that drew up a document establishing the Commonwealth of Puerto Rico. Overwhelmingly approved in a referendum by the voting population and by the U.S. Congress, the commonwealth constitution was proclaimed on July 25, 1952. This process reaffirmed the post of an elected governor, created a legislative branch in which minority representation was guaranteed, and set up a modern judicial system based on civil liberties.

The commonwealth constitution

In spite of broad popular support for the autonomy of the commonwealth government and a rapidly modernizing industrial society, there were expressions of dissatisfaction. Puerto Rican extremists dramatized their desire for independence with an attempt to assassinate President Truman on Nov. 1, 1950, and on March 1, 1954, four of them fired weapons from the viewing galleries of the House of Representatives, wounding five congressmen.

Efforts to improve the commonwealth by expanding its local autonomy to include, for example, a greater presence in foreign, particularly regional or Caribbean, affairs failed. Nevertheless, legal reviews in the courts, both insular and federal, continued to enforce the commonwealth concept. The granting of statehood to Alaska and Hawaii, the growing dependence on federal programs for the unemployed, the aged, and the veterans of the Korean and, later, Vietnam wars, and the sizable influx of Cuban exiles all contributed to a growing sentiment in favour of statehood; a commission was appointed to explore the various political options. In a 1967 plebiscite, however, the commonwealth status was overwhelmingly approved. (T.G.Ms.)

Although commonwealth status won impressive support, both the leaders of the PPD and influential members of the U.S. federal government, following the recommendations of the Status Commission, recognized that the commonwealth relationship needed to be improved and the degree of self-government broadened even further. In the 1970s there were an increasing number of expressions of dissatisfaction with the commonwealth status, and terrorist bombings in San Juan and on the mainland were reported to be linked to the independence movement.

Through the 1970s and '80s political sentiment on the island came to be evenly divided between autonomy and statehood, with the small pro-independence group sometimes serving to swing the balance of the political process in one direction or the other. The PPD returned to power briefly from 1972 to 1976, but the pro-statehood party regained power in 1976 under younger, more vigorous leadership. However, in 1984 a second generation of PPD members won election by a narrow margin under the leadership of Rafael Hernández Colón. This narrow victory was repeated by the PPD in 1988. The PNP won the gubernatorial elections of 1992 and '96 under Pedro Rosselló. The mayor of San Juan, Sila Calderón of the PPD, was elected as Puerto Rico's first woman governor in November 2000.

In a 1992 plebiscite, voters narrowly reaffirmed commonwealth status. Statehood was again rebuffed in a 1998 plebiscite, but, because the PPD had argued that the definition of commonwealth on the ballot was inadequate, a majority voted for the "none of the above" option. At the outset of the 21st century, large numbers of Puerto Ricans challenged the U.S. Navy's longtime use of Vieques Island for bombing exercises. Most voters continued to support some form of permanent association with the United States, but activists increasingly called for greater local autonomy, whether under statehood or a commonwealth system of government. (T.G.Ms./Ed.)

For later developments in the history of Puerto Rico, see the BRITANNICA BOOK OF THE YEAR.

THE LESSER ANTILLES

Anguilla

Anguilla, an island in the eastern Caribbean Sea, is a dependent territory of the United Kingdom. It lies about 60 miles (100 kilometres) northwest of Saint Kitts (Saint Christopher) and is the most northerly of the Leeward Islands in the Lesser Antilles. Anguilla has an area of 35 square miles (91 square kilometres). The Valley is the principal town and the administrative centre of the island.

PHYSICAL AND HUMAN GEOGRAPHY

The land.   Anguilla is bare and flat and is fringed by white sand beaches. Its long thin shape (16 by 3.5 miles) gave it its name (French: *anguille,* "eel"). Anguilla has several small uninhabited offshore islands. The largest are Dog, Scrub, and Sombrero islands and Prickly Pear Cays.

Anguilla is of coral and limestone formation. The highest point is 213 feet (65 metres). Soil is thin, but there are small pockets of red loam, mainly in the shallow valleys. As with most coral islands, water is scarce. The climate is tropical; the average temperature is about 80° F (27° C), and rainfall averages 35 inches (900 millimetres) per year. Hurricanes can occur from July to October and occasionally are highly destructive. The vegetation is primarily low scrub, although there are some plantations of fruit trees.

The people.   The majority of the population of Anguilla is of African descent. The official language is English, and the main religious denominations are Anglican and Methodist.

The economy.   Agriculture is of minor importance. The main economic activities revolve around financial services and tourism. The steady increase in tourism has bolstered the construction industries and stimulated the improvement of transport facilities. Fishing was the traditional livelihood, and both deepwater fishing and fish farming have expanded. The export of fish and lobster is an important source of foreign exchange, as are remittances from émigrés working abroad.

Administration and social conditions.   Executive power is in the hands of a governor (commissioner) appointed by the British monarch. The governor is in charge of external affairs, defense, internal security (including police), and public services. The Executive Council is composed of a chief minister, other ministers, and ex officio members. The House of Assembly consists of members elected by universal adult suffrage, members appointed by the governor after consultation with the chief minister, and ex officio members.

Education is free and compulsory between the ages of 5 and 14. Health conditions are generally good, but health services on the island are limited.

HISTORY

Anguilla may have been reached by Christopher Columbus in 1493. It became a British colony after being settled in 1650 and was administered as part of the Leeward Islands. From 1825 administration was largely through Saint Christopher (Saint Kitts), and Anguilla was incorporated with Saint Christopher and Nevis into a single colony in 1882, a situation to which it thereafter strenuously objected. In 1967, after the three were formed into an associated state, Anguilla complained of the domination by the Saint Christopher administration. Anguilla ejected the Saint Christopher police and set up its own council, subsequently proclaiming its independence. After negotiations failed, the British intervened in March 1969 to restore legal government with troops and a temporary commissioner. The troops were withdrawn in September 1969, and the Anguilla Act of July 1971 placed Anguilla directly under British control. Anguilla formally became a dependent territory of the United Kingdom in 1980, and a new constitution became effective in 1982.

(J.D.Mo./Ed.)

For later developments in the history of Anguilla, see the BRITANNICA BOOK OF THE YEAR.

Antigua and Barbuda

Antigua and Barbuda are islands that form an independent state in the Lesser Antilles in the eastern Caribbean Sea. They lie at the southern end of the Leeward Islands chain and have an area of 171 square miles (442 square kilometres). There is one dependency, the small island of Redonda. The capital is St. John's, on Antigua.

PHYSICAL AND HUMAN GEOGRAPHY

The land.   Antigua's coastline is intricate, with bays and headlands fringed with reefs and shoals; several inlets, including Parham and English Harbour, afford anchorage for shipping, and St. John's has a deepwater harbour. The island has an area of 108 square miles. It is mostly low and undulating, but in the west there are volcanic rocks that rise to 1,330 feet (405 metres) at Boggy Peak. An absence of mountains and forests distinguishes Antigua from the other Leeward Islands. Because there are no rivers and few springs, droughts occur despite a mean annual rainfall of some 40 inches (1,000 millimetres). The average January temperature is around 77° F (25° C); that of August, 82° F (28° C). Summer highs can reach 90° F (32° C).

Barbuda, formerly Dulcina, lies 25 miles (40 kilometres) north of Antigua. A coral island, flat and well-wooded, with highlands rising to 143 feet at Lindsay Hill in the northeast, it is 62 square miles in area. Barbuda is without streams or lakes and receives less rainfall than Antigua. Codrington, the only settlement, lies on a lagoon to the west. The climate is similar to that of Antigua.

Redonda, an uninhabited rock, lies 25 miles southwest of Antigua. It rises sheer to a height of 1,000 feet and is 0.5 square mile in area. Phosphate deposits are located there.

The people.   The majority of the population is of African descent. The great majority of the island's inhabitants live in St. John's. The language is English, and most people are Anglican, with minorities of other Protestant sects and of Roman Catholics.

The economy.   Agriculture, once the mainstay of the economy, has been largely supplanted by tourism. Sugar was long the dominant crop on Antigua, but its production is now insignificant. Barbuda was never involved in the sugar plantation system, its inhabitants always having been fishermen and subsistence farmers. Their traditional system of land tenure is threatened by tourism development. Fruits and vegetables, including citrus fruits, mangoes, and eggplants, are now cultivated on the islands. Manufacturing plays a small role in the economy; most activity involves processing agricultural products and making clothing and textiles and concrete blocks. An international airport is near St. John's.

Administration and social conditions.   Antigua and Barbuda is a constitutional monarchy. The British monarch is nominal head of state, represented by a governor-general. The constitution allows for a Senate and a House of Representatives. Executive power is vested in a Council of Ministers headed by the prime minister. Primary and postprimary education is compulsory.

For statistical data on the land and people of Antigua and Barbuda, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

Antigua was visited in 1493 by Christopher Columbus, who named it for the Church of Santa Maria de la Antigua in Seville, Spain. It was colonized by English settlers in 1632 and remained a British possession although it was raided by the French in 1666. The early colonizers were also attacked by Carib Indians, who were once one of the dominant peoples of the West Indies. At first tobacco was grown, but in the later 17th century sugar was found to be more profitable.

The nearby island of Barbuda was colonized in 1678. The crown granted the island to the Codrington family in 1685. It was planned as a slave-breeding colony but never

Marginal notes: Climate — Coastline — Head of state

became one; the slaves who were imported came to live self-reliantly in their own community.

Emancipation of the slaves

The emancipation in 1834 of slaves, who had been employed on the profitable sugar estates, gave rise to difficulties in obtaining labour. An earthquake in 1843 and a hurricane in 1847 caused further economic problems. Barbuda reverted back to the crown in the late 19th century, and its administration came to be so closely related to that of Antigua that it eventually became a dependency of that island.

The Leeward Islands colony, of which the islands were a part, was defederated in 1956, and in 1958 Antigua joined the West Indies Federation. When the federation was dissolved in 1962, Antigua persevered with discussions of alternative forms of federation. Provision was made in the West Indies Act of 1967 for Antigua to assume a status of association with the United Kingdom on Feb. 27, 1967. As an associated state, Antigua was fully self-governing in all internal affairs, while the United Kingdom retained responsibility for external affairs and defense.

Independence movement

By the 1970s Antigua had developed an independence movement, particularly under its prime minister George Walter, who wanted complete independence for the islands and opposed the British plan of independence within a federation of islands. Walter lost the 1976 elections to Vere Bird, who favoured regional integration. In 1978 Antigua reversed its position and announced it wanted independence. The autonomy talks were complicated by the fact that Barbuda, long a dependency of Antigua, felt that it had been economically stifled by the larger island and wanted to secede. Finally, on Nov. 1, 1981, Antigua and Barbuda achieved independence, with Vere Bird as the first prime minister. The state obtained United Nations and Commonwealth membership and joined the Organization of East Caribbean States. Bird's party won again in 1984 and 1989 by overwhelming margins, giving the prime minister firm control of the island's government.

(R.To./D.L.N./J.D.Mo.)

For later developments in the history of Antigua and Barbuda, see the BRITANNICA BOOK OF THE YEAR.

Barbados

Barbados is an independent island nation in the Caribbean, situated about 100 miles (160 kilometres) east of the Windward Islands. Roughly triangular in shape, it measures 21 miles from northwest to southeast and about 14 miles from east to west, with a total area of 166 square miles (430 square kilometres). Its capital is Bridgetown, the only seaport.

Barbados is not part of the Lesser Antilles, although it is sometimes grouped with this archipelago. The island is of different geologic formation; it is less mountainous and has less variety in plant and animal life. The geographic position of Barbados has profoundly influenced the island's history, culture, and aspects of its economic life. In the era of sailing ships, access to the island was difficult because of the prevailing winds from the northeast. Outward-bound ships from Europe had to gain the island while heading west, for it was difficult for them to turn and reach its shores by sailing eastward against the wind. It remained a British possession without interruption from its settlement in the 17th century to 1966, when it attained independence. As the first Caribbean landfall from Europe, Barbados has functioned since the late 17th century as a major link between western Europe (mainly Britain), eastern Caribbean territories, and parts of the South American mainland. Because of its long association with Britain, the culture of Barbados is probably more British than that of any other Caribbean island. Since independence, however, cultural nationalism and regional awareness have tended to increase.

PHYSICAL AND HUMAN GEOGRAPHY

The land. The rocks underlying Barbados consist of sedimentary deposits, including thick shales, clays, sands, and conglomerates, laid down approximately 70 million years ago. Above these rocks are chalky deposits, which were capped with coral before the island rose to the sur-

The coral surface

face. A layer of coral up to 300 feet (90 metres) thick covers the island, except in the northeast physiographic region known as the Scotland District, covering 15 percent of the area, where erosion has removed the coral cover. The government has adopted a conservation plan to prevent further erosion.

Relief, drainage, and soils. Mount Hillaby, the highest point in Barbados, rises to 1,115 feet (340 metres) in the north central part of the island. To the west the land drops down to the sea in a series of terraces. East from Mount Hillaby, the land declines sharply to the rugged upland of the Scotland District. Southward, the highlands descend steeply to the broad St. George Valley; between the valley and the sea the land rises to 400 feet to form Christ Church Ridge. Coral reefs surround most of the island.

There are no rivers or lakes and only a few streams, springs, and ponds. Rainwater percolates quickly through the underlying coralline limestone cap, draining into underground streams that discharge off the leeward coast. These streams are the main source of the domestic water supply.

Barbados has mainly residual soils. They are clayey and rich in lime and phosphates. Soil type varies with altitude; thin black soils occur on the coastal plains, and more-fertile yellow-brown or red soils are usually found in the highest parts of the coral limestone.

Climate. The climate is generally pleasant. The temperature does not usually rise above 86° F (30° C) or fall below 72° F (22° C). There are two seasons: the dry season, from early December to May, and the wet season, which lasts for the rest of the year. Average rainfall is about 60 inches (1,525 millimetres) a year, but, despite the small size of the island, rainfall varies, rising from the low-lying coastal areas to the high central district. Barbados lies in the southern border of the Carribean hurricane zone, and hurricanes have caused great devastation.

Rainfall

Plant and animal life. Very little of the original vegetation remains on Barbados; the pale green of sugarcane has become the characteristic colour of the landscape. Tropical trees, including poinciana (flamboyant), mahogany, frangipani, and cabbage palm, are widespread, and flowering shrubs adorn parks and gardens.

The few wild animals, such as monkeys, hares, and mongooses, are considered pests by farmers. Birds include the dove, hummingbird, sparrow, egret, and yellow breast. The marine life includes flying fish, sprat, green dolphin, kingfish, barracuda, mackerel, and parrot fish.

Hubertus Kanus—Photo Researchers

The cramped docking facilities of the Careenage, the old harbour, at Bridgetown, Barbados.

Settlement patterns. Barbados is densely populated. More than one-third of the population is concentrated in Bridgetown and the surrounding area. Most of the farmland is owned by large landowners or corporations. As a result, "tenantries" are as common as villages. Tenantries are clusters of wooden houses—locally known as chattel houses—located on the borders of the large estates; they are usually owned by the occupants but stand on rented ground from which they may easily be removed. Most of them have electricity and running water. The largest town is Bridgetown. In its commercial and administrative centre, multistory buildings are altering the features of the 19th-century town. Apart from Bridgetown, Oistins, Holetown, and Speightstown are the largest towns.

The people. Blacks make up more than 90 percent of the population; the remainder consists of whites, persons of mixed African and European descent, and East Indians. English is the official language, and a nonstandard English called Bajan is spoken. The Anglican church has the largest congregation. About a quarter of the population belongs to other Protestant churches, and there is a small number of Roman Catholics.

Demographic trends

Since the 1950s the rate of population growth has been slowed by a successful family-planning program and by emigration, now mostly to other parts of the Caribbean and to North America. In the same period the death and infant mortality rates declined sharply, and life expectancy rose above 70 years.

The economy. Barbados has a small, market-oriented, developing economy. Services, manufacturing, and agriculture are the main productive sectors. Although Barbados had a relatively high per capita growth rate in the 1980s, unemployment, especially among the youth and women, has been a serious problem. Most of the employment is in services and distributive trades, the greater part of which has been unionized.

Resources. Apart from some small deposits of oil and natural gas, Barbados has few natural resources. Sustained exploitation of the climate and beaches for their tourist potential has been the most impressive feature of ongoing economic activity. An overly abundant population may also be considered one of the island's resources. This has always provided a cheap labour source, and the population working abroad has made significant contributions to the economy through remittances.

Agriculture and fishing. About three-quarters of the land is arable, and most of it is planted with sugarcane. Sugar production dominated the economy until the 1950s, but that industry has since declined in importance. Agricultural production remains dominated by large farm units, but the pattern of production has changed, mainly as a result of falling sugar prices and of government-sponsored programs of agricultural diversification and limited land settlement. As a result, there has been significant growth in food production (vegetables, fruits, and livestock), mainly for local consumption. Cotton is also grown.

Fishing has always been part of the island's basic economy, and the government has supported the industry with modernization programs.

Industry. Apart from some quarrying of clay, limestone, and sand, the mining industry is limited to oil and natural gas production and to the refining of imported crude oil for local needs. Crude oil production accounts for about one-third of local needs. Manufacturing industry, stimulated by government incentives, is one of the main growth areas of the economy. Tourism is a fast-growing segment of the economy and the chief foreign-exchange earner.

Finance and trade. Barbados' banking system consists of commercial banks (mostly branches of international banks), a central bank, and various development-oriented financial institutions. A small securities exchange, trading in the stock of locally owned companies, has operated since 1987. During the 1980s there was considerable growth in the offshore financial sector.

Exports

The chief exports include electrical components, processed foods, clothing, furniture, and chemicals. Principal imports include food products, machinery, and fuels. Barbados' main trading partners are the United States, the United Kingdom, and Trinidad and Tobago and other members of Caricom (Caribbean Community and Common Market).

Transportation. The island has a network of good roads. Bridgetown has a deepwater harbour, and several international airlines and British West Indian Airways offer regular services to Grantley Adams International Airport near the southern coast.

Administration and social conditions. *Government.* The constitution of 1966 established a governmental structure based on the British parliamentary system. The British monarch is the head of state and is locally represented by a governor-general. A prime minister, a cabinet, an elected House of Assembly, and a nominated Senate are the main governmental institutions. The Democratic Labour Party (founded in 1955) and the Barbados Labour Party (founded in 1938) are the main political parties. The legal voting age is 18. The Supreme Court of Judicature consists of the High Court and Court of Appeal. Magistrates' courts have civil and criminal jurisdiction.

Education. Barbados has a literacy rate of 98 percent, which is attributable to its comprehensive, mainly government-funded primary-school system. The government places high priority on education; it allocates more than 20 percent of its budget to education, and all education in public institutions is free. Facilities for secondary, technical, and vocational education have expanded rapidly since the 1960s; a polytechnic, a community college, and several new secondary schools have been established. Most training at the university level is done at the University of the West Indies, which maintains a campus at Cave Hill in Barbados.

Health and welfare. Social conditions have been upgraded by political changes since World War II and by improvement in the economy. Sustained efforts by government agencies in sanitation, public health, and housing have significantly improved health conditions. The diseases associated with poverty and underdevelopment have been eliminated or controlled. Health care is provided by both public and private agencies. Other areas of social welfare, notably child care, family life, pension plans for the elderly and disabled, public aid, and the status of women, have benefited from government attention. Community centres and playing fields have been established in most parts of the island.

Cultural life. Barbados has a museum and a public library system. There are daily newspapers and local radio and television stations. The country also has dramatic groups, schools of dancing, and art exhibitions. Barbados is internationally known for cricket.

For statistical data on the land and people of Barbados, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

Little of the island's prehistory is known, but archaeological investigation indicates that Amerindians probably lived on the island from about AD 500 to 1500. The first contact with Europeans may have occurred in the early 16th century when Spaniards visited Barbados on one of their raids for slave labourers. By the mid-16th century—largely because of the island's small size, remoteness, and depopulation—the Spanish had effectively abandoned their claims to its possession.

Original inhabitants

British rule. English colonists established a settlement in 1627 without challenge from either Amerindians or Spaniards. The early period of English settlement was marked by the insecurity resulting from infrequent provision of supplies from Europe and the difficulty in establishing a profitable export crop. This was complicated by bitter squabbles over the claims of rival lords proprietors and over the question of allegiance to either king or Parliament, resulting in the entrenchment of representative governmental institutions by the 1660s.

The search for a profitable export crop ended in the 1640s when Dutch assistance enabled the colonists to convert from tobacco and cotton cultivation to sugar production. This decision had momentous social, economic, and political consequences. Sugar needed a larger labour force than was available and larger farm units than had

previously existed. The importation of African slaves was intensified, and the small farms were amalgamated into plantations. The character of the population changed: in the early 1640s there were probably 37,000 whites and 6,000 blacks; by 1684 there were about 20,000 whites and 46,000 blacks; and, when slavery was abolished in 1834, there were 15,000 whites and 88,000 nonwhites. Sugar was a scarce and therefore valuable commodity in European markets, and Barbadian sugar planters, particularly in the 17th century, reaped huge profits out of the early lead that the island established in sugar production. Increasing wealth brought consolidation of political power for a planter elite. Though slaves continually resisted their bondage, the effective authoritarian power of planter-slave-owners ensured that, apart from the 1816 slave rebellion, there was no effective threat to their control.

Sugar dominance

Sugar remained "king" in Barbados even through the 19th-century crises caused by slave emancipation, free trade, and beet sugar competition. This was mainly because a dense population provided cheap labour, and because the white planter–merchant elite's political power ensured that government resources would be used to rescue the industry in any emergency. The workers therefore carried the burden in low wages and minimal social services. This situation encouraged emigration (often frustrated by the elite) and occasional, futile political protests such as the Confederation Riots of 1876.

By the 1930s the social and political pressures from below could no longer be contained. Population increase, the closing of emigration outlets, the economic effects of the worldwide depression, and the spread of socialist ideology and the black nationalist movement of the Jamaican leader Marcus Garvey had created conditions for a labour revolt. By then, middle-class reformers had begun to agitate against the restricted political franchise (the right to vote was limited to males and restricted by income and property qualifications) and the inadequate social services.

Out of the labour disturbances of 1937 emerged a clear challenge to the existing order. The British government's response assisted this successful challenge. The West Indies Royal Commission (Moyne Commission), dispatched in 1938 to report on social and economic conditions in the British West Indies, endorsed some of the political and social reforms that were advocated by the leaders of the new mass organizations, particularly the full legalization of trade unions and the extension of the political franchise. The implementation of these reforms during the 1940s provided the essential base for the institutionalization of mass political organizations, which became the principal means through which the elite's political power was curtailed. In Barbados black political leaders gained ascendancy by 1944, the same year in which women were granted the right to vote; universal adult suffrage was adopted in 1951, and full internal self-government was achieved in 1961.

Independence

Independence.   Barbados became independent on Nov. 30, 1966, after joining the ill-fated West Indies Federation (1958–62). By then the economy was expanding and diversifying, mainly as a result of the policies pursued by the governments formed after the planter–merchant elite lost power.

Barbados is a member of the Commonwealth and continues to play a leading role in the establishment of regional cooperation. In 1968 Errol Barrow, the prime minister in 1966–76 and 1986–87, helped form the Caribbean Free Trade Area, which became Caricom in 1973. The island has also established close ties with Third World countries. Throughout the 1980s Barbados had one of the most stable political systems in the English-speaking Caribbean.

(C.S.J./W.K.M.)

For later developments in the history of Barbados, see the BRITANNICA BOOK OF THE YEAR.

Dominica

Dominica, a Caribbean island, lies between the French islands of Guadeloupe and Marie-Galante to the north and Martinique to the south. It has been a member of the Commonwealth since independence in 1978. It is 29

miles (47 kilometres) long, has a maximum breadth of 16 miles, and is 290 square miles (750 square kilometres) in area. The capital and chief port is Roseau.

PHYSICAL AND HUMAN GEOGRAPHY

The land.   *Relief, drainage, and soils.*   The island is of volcanic formation, signs of activity including solfataras (volcanic vents) and hot springs. A range of high, forest-clad mountains runs north to south, broken in the centre by a plain drained by the Layou River, which flows to the west; the highest points are Mount Diablotin (4,747 feet [1,447 metres]) and Mount Trois Pitons (4,670 feet [1,424 metres]). In the south, Boiling Lake lies 2,300 feet above sea level; its waters are often forced three feet above normal by the pressure of escaping gases. The soil is rich, and the numerous rivers are all unnavigable.

Climate.   Dominica has a pleasant climate, particularly during the cool months from December to March. Summer temperatures reach an average high of 90° F (32° C); winter temperatures are not much lower, the average high being anywhere from 84° to 86° F (29° to 30° C). The dry season is from February to May, and the rainy season is from June to October, the most likely period for hurricanes. Rainfall varies, being especially heavy in the mountainous interior. Average annual coastal rainfall varies from about 60 inches (1,500 millimetres) to 145 inches (3,700 millimetres), but in the mountains average rainfall can reach 250 inches (6,350 millimetres).

Plant and animal life.   Dominica is the most heavily forested island of the Lesser Antilles. The forest is the habitat of a considerable variety of birds and animals. Two parrots—the imperial parrot, or sisserou (*Amazona imperialis*) and the smaller red-necked parrot (*Amazona arausiaca*)—are found only in Dominica. There are many hummingbirds, of which the blue-headed (*Cyanophaia bicolor*) is native only to Dominica and the neighbouring island of Martinique. Large frogs, known as crapaud or mountain chicken, are a culinary delicacy.

The people.   The population is mainly of African descent, with some Europeans, Syrians, and Caribs. Dominica is the only island with a relatively large and distinctive group of Carib Indians, descendants of the people who inhabited the island before European colonization. Most of the remaining Caribs, a small number of whom are pure-blooded, live in the 3,000-acre (1,214-hectare) Carib Reserve. English is the official language, but a French patois is commonly spoken, and the original Carib language is evidenced in a number of place names. The majority of the population is Roman Catholic, but there also are Methodists, Pentecostals, and Seventh-day Adventists. Dominica experienced out-migration throughout the 1970s, a trend that culminated in a massive exodus after Hurricane David in 1979. This trend, however, reversed in the 1980s.

Predominance of people of African descent

The economy.   Dominica is one of the poorest of the Caribbean nations, its economy dependent upon agriculture, which is intermittently destroyed by hurricanes. Attempts to diversify have had minimal success.

Resources.   Pumice, a volcanic rock used chiefly for building purposes, is the most important commercial mineral. There are also deposits of clay and limestone.

Agriculture, forestry, and fisheries.   Agriculture remains the most important sector of the economy, in terms of both employment and contribution to the gross national product. The main crops are bananas, citrus fruits, and coconuts. Bananas account for nearly half of Dominica's export earnings. Cocoa, coffee, and vegetables are also produced. The forests have potential for marketable timber. The fishing industry was devastated by Hurricane David, when nearly all of the island's fishing boats were destroyed. Recovery has been slow.

Industry.   Most of the main products and exports are derived from the agricultural industry; they include copra, coconut oil, soap, bay oil, and fruit juices. Wood products, including furniture, are produced from local timber. Portsmouth is the main boatbuilding centre. Imports include food, mineral fuels, and manufactured goods. Tourism has been slow to develop because of poor transport and the lack of hotel facilities and good beaches. The

island has sought to develop preserves of its unique flora and fauna to attract tourists.

Transportation. High rainfall and rugged terrain have impeded road building in Dominica. The first road across the island was not completed until 1956, and it was not until 1984 that a major road rehabilitation project was launched to greatly improve accessibility. The main airport is at Melville Hall, 36 miles from Roseau. A second airport at Canefield, closer to the capital, was opened in 1982. Larger vessels use the deepwater port at Woodbridge Bay near Roseau, but Portsmouth remains the major banana-shipping port.

Administration and social conditions. *Government.* Dominica's government is a parliamentary system, with the parliament consisting of the chief executive and the House of Assembly. Most of the House members are elected, but some, usually called senators, may be either elected or appointed. The chief executive is the president, who has the responsibility of appointing the prime minister, an elected member of the parliament with the support of the majority of its members. Terms of office are for five years, and there is universal adult suffrage.

Education. Primary education is compulsory and free in government-run schools. There are many secondary schools, and a university centre is operated by the University of the West Indies.

Health and welfare. There are several major hospitals. Local medical needs are handled by health centres throughout the island. Intestinal diseases, diabetes, anemia, tuberculosis, and sexually transmitted diseases constitute the major health problems of Dominica.

Cultural life. Carib material culture remains evident in the production and use of dugout canoes and intricate woven baskets. The Department of Culture has encouraged revival of slavery-era traditions, which had almost died out, including Afro-French dances, drama, music, and costumes. The Botanical Garden, although it has lost its collection of exotic plants, provides an idyllic setting for the island's main sport of cricket.

For statistical data on the land and people of Dominica, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

Before colonization the island was a stronghold of the Carib Indians who had migrated from South America, driving out the earlier Arawak Indians. It was named by Christopher Columbus, who sighted it on Nov. 3, 1493, a Sunday (Latin: *dies dominica,* "the Lord's day").

The first colonists · **The French and British colonial period.** The first colonists (1632) were French, but, with the Treaty of Aix-la-Chapelle (1748), Great Britain and France agreed to treat the island as neutral ground and leave it to the Caribs. From this time until 1805, Dominica went back and forth between France and Britain. French planters continued to settle in Dominica until 1759, when the British captured the island. It was formally ceded to Britain in 1763. In 1778, French forces from Martinique captured Dominica. The British recaptured the island in 1783. The French, coming this time from Guadeloupe, again failed to capture the island in 1795. The final French assault on the island was in 1805, and although they burned the capital, Roseau, they were forced to withdraw.

At first administered as part of the Leeward Islands, in 1771 Dominica was made a separate colony. It was rejoined administratively to the Leewards in 1883 and remained thus until 1940, when it was transferred to the Windwards as a separate colony. In 1958 Dominica joined the West Indies Federation. After the federation was dissolved in 1962, discussions for alternative forms of federation took place. These issues were settled by the West Indies Act of 1967, which gave Dominica the status of association with the United Kingdom. Under the 1967 constitution the island became fully self-governing in internal affairs.

Independence. On Nov. 3, 1978, Dominica achieved full independence, with Patrick Roland John as its first prime minister. John's government was implicated in a rumoured invasion of Barbados that was to have been launched from Dominica. In the ensuing Cabinet crisis Oliver Seraphine emerged as the new prime minister (May 1979).

Hurricane David severely damaged the island in August 1979, virtually wiping out the nation's agricultural economy. The hurricane carried away most of the island's topsoil, and it was estimated that it would take 20 years to rebuild what had been destroyed. The economy was set back by Hurricane Allen a year later and in 1989 by Hurricane Hugo. · Hurricane devastation

The winner of the 1980 elections, Eugenia Charles, became the Caribbean's first female prime minister. She had initially formed her party, the Dominica Freedom Party, to oppose legislation limiting freedom of the press. More conservative in her approach than either of her predecessors, she moved Dominica toward closer ties with Barbados. Her government faced several coup attempts in 1981, but these were perhaps of less significance than the plight the country faced in attempting to recuperate from the two hurricanes. Under Charles's administration, however, Dominica made marked advances toward recovery, with considerable decreases in unemployment and inflation. Her party was returned to power in 1985 and became more firmly entrenched in the 1986 elections. Dominica joined with other eastern Caribbean states and the United States in the 1983 invasion of Grenada.

(D.L.N./J.D.Mo.)

For later developments in the history of Dominica, see the BRITANNICA BOOK OF THE YEAR.

Grenada

The island of Grenada, also known as the Isle of Spice, is the southernmost of the Lesser Antilles in the eastern Caribbean Sea about 100 miles (160 kilometres) north of the coast of Venezuela. In 1974 it attained independence within the Commonwealth and membership in the United Nations, the first of the six West Indies Associated States to do so.

Oval in shape, the island is approximately 21 miles (34 kilometres) long and 12 miles wide, with an area of 120 square miles (311 square kilometres). The southern Grenadines—the largest of which is Carriacou, about 20 miles north-northeast, with an area of 13 square miles—are a dependency.

The capital, St. George's, on the southwest coast, is also the main port, having a fine natural harbour as well as picturesque pastel-coloured houses that rise up the hillsides from the waterfront. The waterfront itself is known as the Carenage because island schooners were once careened (beached for cleaning or repair) there. St. George's is the yachting and charter-boat centre of the eastern Caribbean. · The capital

The land. *Relief.* Grenada is volcanic in origin, with a ridge of mountains running north and south—the steeper slopes to the west and a more gradual incline to the east and southeast. The highest point is Mount St. Catherine (2,757 feet [840 metres]) in the northern part of the interior. The landscape is scenic, with fairly deep, steep-sided valleys and about 10,000 acres (4,000 hectares) of forest.

Drainage and soils. Several short, swiftly flowing streams supply all towns and most villages with piped clean water. A further source of water is Grand Etang, a lake covering 36 acres in the crater of an extinct volcano at an elevation of 1,740 feet. The fertile soils are chiefly volcanic, with some limestone in the north.

Climate. The island has equable temperatures varying with altitude and averaging 82° F (28° C). Rainfall is adequate, except in the Point Salines area in the southwest; it varies from an average of 60 inches (1,500 millimetres) in coastal districts to more than 150 inches in the mountainous regions. The rainy season lasts from June to December. November is the wettest month, but showers occur frequently during the other months. Grenada lies south of the usual track of hurricanes, but when they do occur, as in 1955, 1979, and 1980, they often cause extensive damage.

Plant and animal life. The island is verdant, with a

Forests   year-round growing season and a wide variety of tropical fruits, flowering shrubs, and ferns. There are also forests of teak, mahogany, saman (known as the rain tree), and blue mahoe (a strong-fibred tree) in the interior.

The animal life is varied and includes such wild animals as the mona monkey (a small, long-tailed, West African species that was introduced by slaves), the manicou (a species of opossum), the agouti (a rabbit-sized rodent, which is brown or grizzled in colour), the iguana, the mongoose, and a variety of turtles and land crabs.

The people. Most of the population is black, having descended from African slaves, and there is a large minority of mulattoes and other mixtures. There are also small minorities of East Indians, descendants of indentured labourers brought to replace the freed slaves; descendants of the old French and British settlers; and more recent immigrants from North America and Europe. Although English is the accepted language, a form of patois is still spoken by older people in the villages. A majority of the population is Roman Catholic; other Christian denominations include Anglicans (more than a fifth of the population), Methodists, and Seventh-day Adventists. Although Grenada is densely populated, its population grew slowly during the 20th century.

The economy. Agriculture and tourism are the most important sectors of the economy, although fishing and agriculturally based industries are becoming more significant. Grenada relies on financial support from the United Kingdom and other sources to bolster the economy.

Agriculture, forestry, and fisheries. To a greater extent than in most West Indian islands, Grenada's arable land is divided into small holdings on which peasant proprietors cultivate diversified crops. Because of these small holdings and the generally hilly terrain, mechanical tilling is rare. The major agricultural export crops—cocoa, bananas, nutmeg, and mace—in the past were controlled by cooperative associations, but these associations have begun to come under greater government control. Banana exports depend upon preferential terms given by the United Kingdom and are affected by the policies of the European Community. Exports of mace and lime juice provide substantial earnings. Copra and, increasingly, other products processed from the coconut are also exported, and a wide variety of tropical fruits—mangoes, passion fruit, guavas, tamarind, and citrus fruits—are grown. The government has encouraged increased production of staple vegetables, such as peas, tomatoes, sweet potatoes, pumpkins, and corn (maize).

The island's forests yield mostly teak and mahogany, and the government has worked to upgrade fishing.

Tourism   *Industry and trade.* Tourism, a major factor in the island's economy, has been encouraged by the government. Air transport facilities have been improved, and the harbour is visited by numerous cruise ships. Other sources of employment are such secondary industries as clothing manufacture, sugar milling, brewing, rum distilling (a strong white rum being made for local consumption), food canning, copra processing, cigarette manufacturing, and soapmaking. There is a cotton ginnery on Carriacou.

The United Kingdom is Grenada's principal trading partner. Exports go largely to Trinidad and Tobago, the United Kingdom, Germany, and The Netherlands; most imports come from the United Kingdom, the United States, and Trinidad and Tobago.

Transportation. Bus service is available between the larger towns and villages. An international airport at Point Salines was inaugurated in 1984. Pearls Airport—providing service to nearby islands with connecting flights to Venezuela—is located on the northeastern coast. An airport on Carriacou also provides flights to nearby islands.

The harbour at St. George's has berths for oceangoing vessels, as well as a yacht basin and service facilities. Several shipping lines maintain regular passenger and cargo services to North America, the United Kingdom, Europe, and neighbouring West Indian islands.

Administration and social conditions. *Government.* Grenada is governed as a constitutional monarchy, with the British monarch represented by a governor-general as the nominal head of state. Executive authority is vested in

a prime minister, who is the head of the majority party in the elected House of Representatives, the lower house of the two-chamber legislature. The Senate is appointed by the governor-general on the advice of the prime minister and the opposition leader.   The legislature

Education. School attendance is not compulsory, although primary and secondary education is free. Grenada has vocational and technical schools as well as the St. George's University School of Medicine and a branch of the University of the West Indies.

Health and welfare. Grenada has several main health centres, as well as district medical stations. Medical and dental treatment in government hospitals and clinics is free. The government has launched a program to eradicate malaria and mongoose-spread rabies.

Culture. The Grenada National Museum in St. George's is dedicated to archaeology and history and houses the Grenada Historical Society. Two Grenadian artists, Elinus Cato and Canute Caliste, have achieved international recognition for their primitive-style paintings. Several weekly newspapers are published, and islandwide radio and television broadcasting is available.

For statistical data on the land and people of Grenada, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

Grenada was sighted by Christopher Columbus on Aug. 15, 1498, when he sailed past the island without landing and gave it the name of Concepción. The origin of the name Grenada remains obscure. After its discovery, Grenada was dominated for 150 years by the warlike Carib Indians, who had earlier killed off the more peaceful Arawak. In 1609 British merchants attempted to form a settlement, but the Caribs forced them to leave.

French settlement. The French governor of Martinique, Jacques-Dyel du Parquet, purchased Grenada from a French company in 1650 and established a settlement at St. George's. Grenada remained French until 1762, when it capitulated to the British. It was formally ceded to Britain in 1763 by the Treaty of Paris. In 1779 it was recaptured by the French, but it was restored to Britain in 1783.

British rule. In the late 18th century the British imported large numbers of slaves from Africa to work the sugar plantations. During 1795 and 1796, when French policy favoured the abolition of slavery, a rebellion against British rule occurred, led by a French planter and supported by the French in Martinique. The rebels massacred a number of the British, including the lieutenant governor, but the uprising was quelled. The emancipation of the slaves finally took effect in 1833.

Grenada was headquarters of the British Windward Islands government from 1885 until 1958, when Grenada joined the West Indies Federation. The federation ended in 1962, after which Grenada attempted to federate with the remaining territories in the Windward Islands, as well as with Barbados and the Leeward Islands. On March 3, 1967, however, the island became a self-governing state in association with the United Kingdom.

Independence. In the general election of August 1967, the Grenada United Labour Party (GULP) defeated the Grenada National Party (GNP) and took office under the premiership of Eric M. Gairy, a trade unionist. Grenada became an independent nation on Feb. 7, 1974. The transition was marked by violence, strikes, and controversy centring upon Gairy, who was named prime minister. Opposition to Gairy's rule continued to mount, and a coalition called the New Jewel Movement (NJM), along with other opposition parties, succeeded in reducing GULP's majority in Parliament in the 1976 election. On March 13, 1979, while Gairy was out of the country, the NJM staged a bloodless coup, proclaimed a People's Revolutionary Government (PRG), and named their leader, Maurice Bishop, as prime minister. The new government faced opposition from Western nations because of its socialist principles, but it embarked on a program to rebuild the economy, which had been left in disarray by Gairy. The PRG administration was ended in October 1983 by a military coup, during which Bishop was killed.   Accession of GULP

Less than a week later, on October 25, a U.S.-led invasion of the island overthrew the coup leaders and returned power to the governor-general, Sir Paul Scoon. In December Scoon appointed Nicholas Braithwaite, a former Commonwealth official, to head a governing council until an election could be held, and constitutional government was restored. A peacekeeping force remained until 1985. The election, held in December 1984, was won by the New National Party headed by Herbert A. Blaize, who had led the government in the 1960s. The new government sought to revive tourism, but Grenada's continuing economic problems throughout the late 1980s contributed to the government's dwindling popularity. Following an election in March 1990, Braithwaite, whose National Democratic Congress fell one seat shy of a parliamentary majority, was appointed prime minister by Scoon. (E.V.B.B./Ed.)

For later developments in the history of Grenada, see the BRITANNICA BOOK OF THE YEAR.

Guadeloupe

Guadeloupe, a French overseas *département,* is a group of islands in the Lesser Antilles chain in the eastern Caribbean Sea. The nearest neighbours of the principal islands are the British dependency of Montserrat to the northwest and the republic of Dominica to the south. The island of Martinique, also a French overseas *département,* lies about 74 miles to the south. The main territory of Guadeloupe consists of the twin islands of Basse-Terre to the west and Grande-Terre to the east, the two being separated by a narrow channel, the Salée River; other islands in the group are Marie-Galante to the southeast, La Désirade to the east, and Saintes Islands (Terre d'en Haut and Terre d'en Bas) to the south. Two more island dependencies—Saint-Barthélemy and Saint-Martin (the southern third of which is administered by The Netherlands as Sint Maarten)—are situated about 150 miles to the northwest, lying to the northwest of the outer arc of the Lesser Antilles.

The total area of Guadeloupe is 687 square miles (1,780 square kilometres). Basse-Terre, on the island of the same name, is the seat of government. The largest urban area, however, centres around Pointe-à-Pitre on Grande-Terre, the chief port and economic hub of Guadeloupe.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief and drainage.* Basse-Terre, which has an area of 364 square miles, has a chain of mountains running north to south and culminating in Soufrière, a volcano 4,813 feet (1,467 metres) high; it erupted in 1797, 1837, and 1976 and is now a source of hot springs and sulfur springs. Other summits of note are the 4,442-foot Mount Sans Toucher and the 4,143-foot Mount de la Grande Découverte. The mountain chain forms a watershed from which rivers run down to the sea. The principal river on the island is the Goyaves; other rivers are the Grande Plaine, the Petite Plaine, the Moustique, the Lézarde, and the Rose. Basse-Terre has a beautiful coastline, indented with bays and fringed with picturesque beaches.

Grande-Terre has an area of 220 square miles and is generally low-lying; it has only a few bluffs higher than 490 feet. Saint-Martin and Saint-Barthélemy are rugged and rise to an altitude of 1,391 feet and 921 feet, respectively.

Climate. The tropical climate is tempered by the northeast trade winds. The temperature on the coast varies between 77° and 82° F (25° and 28° C), with extremes of 68° and 93° F (20° and 34° C). In the mountains above 1,900 feet the temperature may drop to 61° F (16° C), and at the summit of Soufrière to 39° F (4° C). There are two distinct seasons—the "Creole Lent," or dry season, from December to April, and winter, or rainy season, from July to September–October. Precipitation varies with altitude and orientation. Grande-Terre receives approximately 39 inches (990 millimetres) of rain a year, while the mountainous parts of Basse-Terre receive more than 100 inches. Hurricanes occur occasionally, in most cases coming from the south.

Plant and animal life. The heat, rainfall, and fertility of the volcanic soils produce a luxuriant vegetation diversified according to altitude. About two-fifths of the islands' area is covered by forests, most of this on Basse-Terre. Extensive mangrove swamps cover the banks of the Salée River. Dense forest grows in the mountainous regions of Basse-Terre, beginning almost at sea level on the windward slopes and at altitudes of about 750 to 3,000 feet or more on the leeward side. There chestnut trees and bracken are found, as well as such hardwoods as mahogany and ironwood. On the highest peaks some flooded basins produce a vegetation of grasses and sedges. Grande-Terre, cleared of most of its original forests, has only a few patches of woodland. The smaller islands, such as La Désirade and Saint-Martin, have a different type of vegetation, consisting primarily of dry forest with groves of latania (a kind of fan palm) and cactus.

Animal life has been modified since colonization. Raccoons are sought for their fur. The agouti (a short-haired, short-eared, rabbitlike rodent) still inhabits the heights of Capesterre, southeast of Basse-Terre. In some regions, wild ducks, waterfowl, and teal are found.

The warmth of the water around the islands is responsible for a rich variety of marine life, including lobster, crab, octopus, tarpon, snook (a basslike kind of fish), hogfish, snapper, parrot fish, and many species of ray fish.

The people. The population is composed principally of Creoles (*i.e.,* persons born in the islands), most of whom are mulatto, but on Saintes Islands the inhabitants are mainly white. The largest minorities are the black and French-Amerindian groups. The white population greatly declined during the period of the French Revolution. On the smaller islands, whites are mostly descended from 17th-century Norman and Breton settlers. While French is the official language, a local creole dialect is also widely spoken. The majority of people are Roman Catholic.

Guadeloupe's population has a low rate of natural increase compared to other West Indian islands. Its birth and death rates are lower than the Caribbean average but about the same as those of its French counterpart, Martinique. The vast majority of the population resides on the two largest islands; Marie-Galante is the next most populous island, followed by Saint-Martin, Saint-Barthélemy, Saintes Islands, and La Désirade. The islanders' standard of living is among the highest in the eastern Caribbean.

The economy. The economy is marked by a slow-growing agricultural sector, an embryonic industrial sector, a growing tourism sector, and a highly developed public service sector. In effect, the economy is sustained primarily by the salaries of officials and by French credits, which consist of aid in the form of allocations and grants. Tourism is the main source of foreign exchange.

Agriculture and industry. Bananas and sugarcane form the principal cash crops; coffee, vanilla, and cacao are also grown. The banana plantations suffered from a series of hurricanes in the 1960s, but the plantations were replanted with more productive types of trees. The cultivation of fresh vegetables, coconuts, pineapples, limes, mangoes, flowers, and coffee is increasingly important. Eggplants and flowers are chiefly grown for export. Most of the small fish catch is exported. An industrial zone and a free port have been developed at Jarry, near Pointe-à-Pitre. Industry is involved mostly in the processing of agricultural products, especially sugar refining and rum making.

Trade. There is a severe deficit in the balance of external trade, most of which is with France and the Franc Zone. Most imports are consumer goods. Most of the banana crop and raw sugar are exported to France. Rum, coffee, cocoa, and vanilla also are exported.

Transportation. Guadeloupe maintains regular air and sea links with France and with the North American continent. The port of Pointe-à-Pitre is equipped to handle cargoes of minerals, sugar, and cereals. The port of Basse-Terre specializes in the banana export trade. Le Raizet, north of Pointe-à-Pitre, is an international airport used by French, U.S., British, and Dutch airlines. There is a secondary airport on Marie-Galante. On the island of Saint-Martin, the town of Marigot, the capital of the French portion of the island, is an important port; the Juliana International Airport, west of Philipsburg in the Dutch sector, serves both parts of the island. Local steamers connect Basse-Terre and Grande-Terre with the other island

Margin notes:

Principal rivers

Population distribution

dependencies. The road system on the main islands is kept in excellent condition. Except for some privately owned plantation lines, there are no railways in Guadeloupe.

Administration and social conditions. *Government.*
The *département* is under the executive authority of a commissioner appointed by the French government; there is an elected legislative council. Guadeloupe sends representatives to both the French National Assembly and the French Senate. Since 1974 Guadeloupe has had the status of a full *région* of France. The territory of Guadeloupe is divided into three *arrondissements,* which are in turn divided into 34 *communes,* each administered by an elected municipal council.

Justice. The judicial system is French. There are a court of appeal at Basse-Terre, two higher courts (*grande instance*), and four lower courts (*tribunaux d'instance*). Justices of the peace are established in each of the cantons.

Education. French is the medium of instruction. In addition to primary schools, there are lycées (secondary schools) as well as a teacher-training college. A school of humanities, a law and economics school, a school of medicine, and a school of science at Pointe-à-Pitre are part of the University of the Antilles and Guyana.

Health and welfare. The same social legislation is in effect as in metropolitan France. There is a general hospital at Pointe-à-Pitre, as well as a Pasteur Institute and a number of other hospitals and clinics.

Cultural life. Cultural affairs are developed through the Ministry of Culture. Folk culture is of considerable significance, and colourful native costumes, including the unique *madras et foulard,* may still be seen on holidays. Celebrations, particularly the annual carnival, feature Creole music and folk dances, such as the beguine. A number of museums are located in the major cities. Several newspapers are printed on the islands, and radio and television are broadcast daily.

For statistical data on the land and people of Guadeloupe, see the *Britannica World Data* section of the BRITANNICA BOOK OF THE YEAR.

HISTORY

Visited on Nov. 4, 1493, by Christopher Columbus, the two main islands, then together known as Karukera (Island of Beautiful Waters), were peopled by Caribs, who had displaced the original Arawak inhabitants. The territory was consecrated to Our Lady of Guadalupe of Extremadura in Spain, from whom it takes its name.

French rule. Preliminary attempts by the Spanish to establish themselves were repulsed by the Caribs in 1515, 1520, and 1523. In 1626 the Spanish, who had established themselves on the coast, were driven away by Pierre Belain d'Esnambuc, a Frenchman who established a trading company. In 1635 two Frenchmen, Léonard de L'Olive and Jean Duplessis d'Ossonville, landed and established a colony. Until 1640 the colonists fought against the Carib Indians, but thereafter the colony prospered. Four chartered companies were ruined in successive attempts to colonize Guadeloupe, and in 1674 it passed to the French crown, becoming a dependency of Martinique, which it remained until 1775. Guadeloupe benefited from the in-
fluence of Jean-Baptiste Labat (1663 to 1738), a strong personality who was the effective founder of the Basse-Terre colony and who in 1703 armed the African slaves (who had already been brought to the island) in order that they might fight against the English; he also established the first sugar refineries, thereby laying the foundations for the era of prosperity that followed.

In 1759 Guadeloupe was occupied by the British for four years but was restored to France in 1763. In 1794 it was again occupied by British troops, allied with French royalists, but was recaptured by Victor Hugues, an official of the French revolutionary government, who proclaimed the abolition of slavery and had several hundred white planters massacred. When slavery was reestablished by Napoleon's government in 1802, a revolt of the slaves occurred and culminated in the heroic act of the antislavery forces, who blew themselves up at Matouba when threatened by French forces under the command of General Antoine Richepanse; Richepanse himself had been sent

by Napoleon to pacify Guadeloupe, but he died of yellow fever in the same year. The British occupied Guadeloupe in 1810; however, after some changes in status, it was restored to France in 1816.

The abolition of slavery in 1848 was the most significant development of the territory's 19th-century history. Universal suffrage was abolished during the reign of Napoleon III of France, but in 1870 colonial representation in the French Parliament was restored. In 1940 Guadeloupe gave its allegiance to the Vichy government of Nazi-occupied France, but in 1943 it adhered to General Charles de Gaulle's Free French forces. In 1946 it was given the status of a French *département,* and in 1974 it became a *région* of France.

Political and economic changes since World War II. Guadeloupe has had several independence movements since the end of World War II, but the charismatic appeals of de Gaulle, who visited the island in 1956, 1960, and 1964, managed to sidestep the separatists and convince the majority to stay within the French union. More local control has been granted the island since the 1960s, but, as progress on the autonomy talks slowed to a standstill in the 1970s, the separatist groups became increasingly violent. Several bombings were committed in Paris by Guadeloupe independence groups. Despite further acts of violence in the 1980s by these groups and their gains in local government, the French government reiterated its determination to maintain *département* status for Guadeloupe. The lack of economic improvement, however, provided some stimulus to independence groups.   (R.Co./Ed.)

For later developments in the history of Guadeloupe, see the BRITANNICA BOOK OF THE YEAR.

Martinique

The island of Martinique is an overseas *département* of France situated in the eastern Caribbean. It is included in the Lesser Antilles island chain. Its nearest neighbours are the island republics of Dominica, 22 miles to the northwest, and Saint Lucia, 16 miles to the south. The main islands of Guadeloupe, also a French overseas *département,* lie about 74 miles to the north.

Martinique has an area of 436 square miles (1,128 square kilometres) and measures about 50 miles in length and about 22 miles at its widest extent. The second smallest (after Saint-Pierre and Miquelon) of all the French overseas *départements,* Martinique's population density is one of the highest in the Antilles. The administrative capital and chief town is Fort-de-France.

The name Martinique is probably a corruption of the Indian name Madiana ("Island of Flowers") or Madinina ("Fertile Island with Luxuriant Vegetation"), as reputedly told to Christopher Columbus by the Caribs in 1502. Empress Joséphine, consort of Napoleon I, was born on the island in 1763; she was the daughter of a Martinique planter named Joseph Tascher de La Pagerie.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief and drainage.* The mountainous relief of Martinique represents the outermost edge of what remained of the original geologic formation after the subsidence of the trench that became the Caribbean Sea. The relief of the island takes the form of three principal massifs (mountainous masses). These are a still active volcano, Mount Pelée, 4,583 feet (1,397 metres) high, to the north; the Carbet Mountains, of which Lacroix Peak reaches 3,923 feet, in the centre; and Mount Vauclin, 1,654 feet high, in the south.

The tortuous relief of the island has led to a complex drainage pattern, characterized by short watercourses. In the south, the Salée and the Pilote rivers flow down from the scarps of Mount Vauclin. In the centre the rivers flow outward from the Carbet Mountains in a starlike pattern; they include the Lorrain, Galion, Capot, and Lézarde rivers. In the north the Grande River, the Céron River, the Roxelane River, the Pères River, and the Sèche River are little more than irregular torrents.

The northern coastline of Martinique is characterized by steep cliffs; farther south, however, the cliffs become

lower, with two large bays—Fort-de-France and Marin—being located on the western coast. Coral reefs, headlands, and coves line the east coast.

Climate. The climate is remarkably constant, the average temperature being about 79° F (26° C), with average minimums of 68° to 72° F (20° to 22° C), average maximums of 86° to 90° F (30° to 32° C), and temperature extremes of 59° F (15° C) and 93° F (34° C). The northeast trade winds, which blow almost 300 days a year, temper the heat, but winds from the south are hot and humid and sometimes bring hurricanes.

The year consists of two distinct seasons—a relatively dry season, which lasts from December to June, and the rainy winter season from July to December. Rainfall is abundant, especially in July and September, but is very irregularly distributed; it varies from about 40 inches (1,000 millimetres) to almost 400 inches a year, depending upon elevation and the orientation of the relief.

The four vegetation zones

Plant and animal life. The climate, together with the fertile volcanic soil, produces a luxuriant vegetation, which is divided, according to altitude, into four zones: the maritime zone, the lowlands, the former forest zone, and the upper mountain slopes. The maritime zone includes an enormous mangrove swamp, half of which is located in the bay of Fort-de-France. The beaches are invaded by morning glory, tropical twining herb, and sea grape. The lowland vegetation zone, extending from the coast to a height of about 1,500 feet, has ferns and orchids, as well as various trees, including mahogany, white gum, and other species. Above 1,500 feet is the former virgin forest zone, where large trees and bracken are still to be found. As the altitude increases the trees grow smaller. A transitional zone is characterized by peat moss. Above 3,000 feet the upper slopes are almost bare, except for some stunted forest. Forests cover about one-fourth of the total land area.

There are relatively few kinds of animals on the island. The mongoose was introduced in the 19th century in the hope of eliminating the deadly rat-tailed viper, but without doing so. Also found are the manicou (a kind of opossum), wild rabbit, wild pigeon, turtledove, and ortolan (a small bird about six inches long, often netted and fattened as a table delicacy).

The people. In 1658 French settlers on the island numbered about 5,000. The Carib element gradually disappeared, partly as a result of conflicts and partly as a result of assimilation. The importation of slaves from Africa added a further ethnic component. Today the racial composition of the island is extremely mixed, but the mulatto element is the largest. The white Creole (locally born) element, however, controls an important part of the island's economy. A creole dialect, similar to that spoken in Haiti, is commonly heard, but French is the official language. The majority of the population is Roman Catholic.

The population of Martinique increased rapidly until the late 1970s, when, plagued by unemployment and other economic maladies, the residents of the island began to emigrate in large numbers to France and in smaller numbers to French Guiana. As a result of the high growth rate in the 1950s and '60s, almost two-fifths of the population is under age 20. About a third of the total population lives in the capital city of Fort-de-France.

The economy. Martinique has a typically Caribbean economy, depending heavily on a few agricultural products and tourism and relying on outside sources, principally France, for aid. A huge trade deficit and a high rate of unemployment are major impediments to economic progress. Nevertheless, the island enjoys one of the higher standards of living in the Caribbean.

Cash crops

Agriculture. The principal agricultural products are sugarcane and bananas, grown chiefly for export. Fresh and canned pineapples, cut flowers, avocados, eggplants, and citrus fruits are other exports. Grown for the domestic market are yams, cassava, sweet potatoes, and breadfruits. Fishing of crab, lobster, clams, cod, and crayfish is mainly for domestic use. The destruction of most banana plantations by Hurricane Allen in 1980 was a major setback.

Industry. Economic planning has laid emphasis on land reform (providing certain planters with lands that have been insufficiently reclaimed from swamp), the di-

versification of agricultural crops, and industrialization. Local industry includes cement, fertilizer, and polyethylene plants and an oil refinery at Fort-de-France. Other industries include rum distilling, fish and fruit canning, sugar refining, the processing of cattle feed, soft drinks, and food, and the manufacture of pottery, wooden furniture, and chemicals. The growth of light manufacturing is being encouraged. One of the most popular tourist areas in the Caribbean, Martinique has a flourishing cruise ship business that brings tourists mainly from France, Canada, and the United States.

Trade. Martinique's economy is heavily dependent on trade with France, which provides about two-thirds of the island's imports and receives more than three-fifths of its exports. The value of imports far surpasses the value of exports, resulting in large trade deficits. Exports include refined petroleum products in addition to agricultural products; chief imports are foodstuffs, consumer goods, petroleum products, and electrical machinery.

Transportation. Martinique maintains regular air and sea links with France and North America. The main port is Fort-de-France. There is an international airport at Lamentin, to the east of Fort-de-France. The road network links Fort-de-France by an expressway with coastal towns. There are local bus services, and small coastal steamers connect various points around the island.

Administration and social conditions. *Government.* As an overseas *département,* Martinique is divided into three *arrondissements,* comprising 34 *communes,* each of which is administered by an elected municipal council. Executive authority is represented by a commissioner and other officials, and there is an elected legislative council. Martinique is represented in the French National Assembly, in the French Senate, and on the French Economic and Social Council. Since 1974 Martinique has also had the status of a full *région* of France.

Justice. The French system of justice is in force. The Court of Appeal at Fort-de-France also has jurisdiction over Guadeloupe and French Guiana. There are two higher courts (*grande instance*), two lower courts (*tribunaux d'instance*), one administrative court, and a commercial court.

Education. Free and compulsory education is provided for children between six and 16 years of age. There are primary, secondary, and vocational schools. The enrollment of children of school age is exceptionally high. Higher education is usually pursued in metropolitan France, for which a number of scholarships are available. Institutes of law and economics, letters and human studies, and Creole studies constitute part of the University of the Antilles and Guiana.

Higher education

Health and welfare. There are several general and maternity hospitals, as well as some dispensaries. Martinique receives the same social benefits as mainland France.

Cultural life. The Fort-de-France carnival, featuring a parade with masks, is an annual event. Voodoo ceremonies are far less important on the island than they are in Haiti. Cockfighting is a popular sport.

For statistical data on the land and people of Martinique, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

The Caribs inhabited the island at the time Christopher Columbus sighted it in 1493. It was not until 1502, on his fourth voyage, that he visited the island, leaving there some pigs and goats. Neglected by the Spaniards, who sought more material rewards than those the island offered, Martinique was occupied in 1635 by a Frenchman, Pierre Belain d'Esnambuc, who established 80 settlers at Fort-Saint-Pierre at the mouth of the Roxelane River. A year later d'Esnambuc, who had fallen sick, entrusted Martinique to his nephew, Jacques-Dyel du Parquet, who bought the island from the Compagnie des Isles d'Amérique and developed it into a remarkably prosperous colony. In 1654 a group of 250 Dutch Jews, chased from Brazil by the Portuguese, introduced sugarcane. In 1660 cacao trees were planted in place of cotton.

French rule. After the death of du Parquet, his widow governed the island in the name of her children but

disagreed with the settlers; and in 1658 the French king, Louis XIV, resumed sovereignty over the island, paying an indemnity to du Parquet's children. In 1664 the island was placed under the authority of the Compagnie des Indes Occidentales; in 1674 it was made part of the French crown domain, being administered according to the Pacte Colonial, a body of principles summarized in the statement, "The mother country founds and maintains the colonies; the colonies enrich the mother country." Supplies and slaves were brought out to the French Antilles by the Compagnie du Sénégal, founded in 1664; slave ships called at Martinique before proceeding to Guadeloupe. In 1723 Arabian coffee was introduced, thus further contributing to the island's prosperity. In 1787 Louis XVI granted Martinique the right to establish a colonial assembly.

An attack by the Dutch was repulsed in 1674, and further attacks by the English were repelled in 1693 and in 1759. In 1762, however, the English captured the island, only to return it to France under the terms of the Treaty of Paris in 1763. The English recaptured it in 1794 and occupied it until 1802; captured once more by the English in 1809, it was definitively restored to France in 1814. Slave uprisings occurred in 1789, 1815, and 1822. Following the abolition of slavery in 1848, labourers from India and China were introduced. Universal suffrage was proclaimed in 1848 but was abolished once more under Napoleon III; after 1870 the Third Republic of France restored representation for the island in the French Parliament.

In 1902 the volcanic eruption of Mount Pelée destroyed the town of Saint-Pierre, killing about 30,000 people. During World War II Martinique adhered to the Vichy government of Nazi-occupied France for three years before rallying to the Free French cause in 1943. In 1946, Martinique was granted the status of a French *département*, and in 1974 it was made a *région*.

Developments since World War II. Martinique, more vociferous in its demands for independence than Guadeloupe, was heavily influenced by Aimé Césaire, the Martinique writer who was one of the founders of the Negritude movement. Césaire, first elected as a deputy in 1945, was a member of the Communist Party; in 1956 he resigned and formed the Progressive Party of Martinique. In 1957 Césaire's party won the Martinique elections by an enormous margin.

Martinique's economy was depressed, and emigration to France and French foreign aid had always been palliative for Martinique's economic problems. Thus, demands for independence resulted only in Martinique's being given greater autonomy. Political unrest grew, and by the late 1970s the French government, in an apparent about-face, decided to help Martinique become economically self-sufficient in preparation for independence. Hurricanes caused widespread destruction in 1979 and 1980. Liberation groups were responsible in the 1980s for several bombings in Paris and the French Caribbean islands; however, electoral support for independence has been limited. By the 1990s AIDS and drug trafficking had become major concerns. Unemployment and poverty rates have remained far higher than in France.   (R.Co./Ed.)

For later developments in the history of Martinique, see the BRITANNICA BOOK OF THE YEAR.

Montserrat

Montserrat, an island of the Lesser Antilles chain in the Caribbean Sea, is an overseas territory of the United Kingdom. It has an area of about 40 square miles (103 square kilometres). The de facto capital is St. John's, in the northern part of the island. Plymouth, on the southwestern coast, was the capital until 1997, when it was largely destroyed by volcanic eruptions.

PHYSICAL AND HUMAN GEOGRAPHY

The land. Montserrat lies 27 miles (43 kilometres) southwest of Antigua. The island is 11 miles long and 7 miles wide. The Silver Hills, in the north, and the Centre Hills are forested at higher elevations but have secondary scrub on their gentler lower contours. Chances Peak, at 3,000

feet (915 metres) in the Soufrière Hills, was once the highest point on the island. From July 1995 volcanic domes in the Soufrière Hills alternately grew and collapsed in a series of eruptions, killing 19 people in June 1997 and destroying forests and villages. Many of the domes rose higher than 3,300 feet before partly collapsing.

The climate is mild, and there is little seasonal variation. Average temperatures range from 70° F (21° C) to 86° F (30° C). The warmest period is from June to November. Annual precipitation averages about 57 inches (1,448 millimetres). The island is often in the path of hurricanes, the storm in 1989 being particularly devastating.

The people. The population is largely of black African ancestry. The official language is English, but most Montserratians also speak a Creole similar to that of Jamaica. The main religious denominations are Anglican, Methodist, and Roman Catholic; Seventh-day Adventists and Pentecostalists are of increasing importance. Until the mid-1990s Montserrat's population was relatively stable because of emigration and a low birth rate. Plymouth and its environs were the main centres of settlement. During Partial evacuation the volcano crisis more than two-thirds of Montserratians departed for Britain or neighbouring Antigua and other parts of the Caribbean region. Renewed eruptions have discouraged resettlement, and access to the southern two-thirds of the island has been restricted.

Montserratian society has a mixture of African, Irish, and British traditions, with the impact of North American culture becoming more dominant. Carnival, known locally as Festival, is celebrated from December 26 to January 1. St. Patrick's Day (March 17) is a national holiday.

The economy. Volcanic activity caused a virtual economic collapse when Plymouth, the main commercial centre, was abandoned. Montserrat has since relied on British aid to rebuild infrastructure and provide services. The largest sources of employment are now public services and construction. The eruptions damaged most of the island's farms, but some potatoes, onions, carrots, tomatoes, hot peppers, and other vegetables are still produced for the domestic market.

Montserrat's airport was closed because of eruptions in 1997. Since then the island has been linked with Antigua via a ferry terminal at Little Bay, in the northwestern part of the island, as well as by helicopter service.

Administration and social conditions. Montserrat is a self-governing overseas territory within the Commonwealth. The British monarch is the head of state. The constitution, promulgated on January 1, 1960, provides for a governor appointed by the British monarch, an Executive Council, and a Legislative Council. The governor heads the Executive Council and appoints as chief minister the leading member of the Legislative Council.

Education is free and compulsory for children aged 5–14. Nearly all Montserratians are literate. The leading causes of death are diabetes, heart diseases, and cancers. A hospital and branch of the University of the West Indies have been relocated from the capital to the north.

HISTORY

The original inhabitants of Montserrat began arriving in the Lesser Antilles about 3000 BC. The island was sighted in November 1493 by Christopher Columbus, who named it for the abbey of Montserrat in Spain. It was colonized in 1632 by Irish Catholics from St. Kitts. More Irish immigrants subsequently arrived from Virginia. Plantations The plantation system were set up to grow tobacco and indigo, followed eventually by cotton and sugar. The French captured the island in 1664 and again in 1667, but it was restored to England in 1668 by the Treaty of Breda. French forces sacked the island in 1712 and captured it for the last time in 1782, but the Treaty of Versailles (1783) returned it to Britain.

African slaves were probably first brought to Montserrat in large numbers in the 1660s. Their population grew to nearly 1,000 in 1678 and some 7,000 in 1810. The plantation system declined after slavery was abolished in 1834 and the world market for sugar declined. The Montserrat Company, formed in 1857 under Joseph Sturge, bought abandoned estates, encouraged lime cultivation, and sold plots to settlers. As a result, much of Montserrat is still

owned by small holders. A series of devastating earthquakes and hurricanes occurred between 1890 and 1936.

Between 1871 and 1956 Montserrat was part of the (British) Federal Colony of the Leeward Islands. In 1951 universal suffrage was introduced, and the first election under the new system took place the following year. The federation was abolished on July 1, 1956, when Montserrat became a colony in its own right.

In the general election of 1978 the People's Liberation Movement (PLM) won all seven seats to the Legislative Council. The party retained its control in 1983, but the opposition gained strength in the 1987 election. The PLM favoured independence after first achieving greater economic self-sufficiency. However, many others opposed independence. In the election of 1991 the newly formed National Progressive Party (NPP) took over the government, but in 1996, in the midst of the volcano crisis, it won only one legislative seat. A weak coalition was then formed, headed by Bertrand Osborne, who resigned in 1997 amid criticism of his handling of the volcano crisis. He was replaced by David Brandt. The British government was also criticized for the way it managed the crisis, although it helped evacuate and relocate the population. Volcanic activity continued into the first years of the 21st century.   (P.Pa.)

For later developments in the history of Montserrat, see the BRITANNICA BOOK OF THE YEAR.

Saint Kitts and Nevis

The Federation of Saint Kitts and Nevis (also called Saint Christopher and Nevis) is a sovereign state composed of two islands of the Lesser Antilles in the eastern Caribbean Sea. Their area is 104 square miles (269 square kilometres). The capital is Basseterre on the island of Saint Kitts.

PHYSICAL AND HUMAN GEOGRAPHY

The land. Saint Kitts is 23 miles (37 kilometres) long and five miles wide, is oval in shape, and has an area of 68 square miles (176 square kilometres). A volcanic mountainous ridge down the centre forms a semicircle around a plain in the southeast. Mount Liamuiga (formerly Mount Misery), with a lake in its forested crater, is the highest point (3,792 feet [1,156 metres]). The soil (except in the mountains) is light and porous. Most of the beaches are of black volcanic sands. The island is well watered and fertile, with a cool, healthy climate. The average temperature is 80° F (27° C), and the annual rainfall averages 55 inches (1,397 millimetres).

Climate

Nevis, surrounded by coral reefs, lies two miles southeast of Saint Kitts across a channel known as The Narrows. The island is circular, and it consists almost entirely of a mountain, Nevis Peak (3,232 feet), which is flanked by the lower Round Hill (1,014 feet) on the north and by Saddle Hill (1,850 feet) on the south. Its area is 36 square miles (93 square kilometres). The climate is similar to that of Saint Kitts. Hurricane Georges wreaked unprecedented destruction on the nation in 1998.

The people. The population is largely black, with a small mulatto minority and other mixtures. There are also very small East Indian and white groups. The official language is English. The main religious denominations are Anglican and Methodist, with small groups of Moravians and Roman Catholics. Both Saint Kitts and Nevis have traditionally had high levels of emigration, which offset natural increases and enable the islands to maintain a fairly stable population. Remittances from emigrants form an important source of foreign exchange.

The economy. The narrow coastal plain of St. Kitts, the skirts of the mountains, and the Basseterre Valley have long been devoted to the cultivation of sugarcane (mainly on large estates), which is the chief export. However, after a drop in world sugar prices hurt exports during the mid-1980s, the government sought to diversify the economy. Nevis grows chiefly cotton, vegetables, and coconuts. Light industries in Saint Kitts and Nevis produce electronic equipment, batik-dyed fabrics, and other clothing and furniture. Tourism is also an important sector of the economy. The United States, the United Kingdom, and Trinidad

and Tobago are the principal trading partners. There is a deepwater port at Basseterre, and Golden Rock International Airport on Saint Kitts provides service to other islands and to the United States and Canada. Newcastle Airfield on Nevis provides interisland air service.

Administration and social conditions. Saint Kitts and Nevis is an independent member of the Commonwealth, with the British monarch as its head of state. An appointed governor-general represents the crown. The prime minister, who together with other ministers is a member of the Cabinet, is the head of government. The monarch and the National Assembly constitute the parliament, some of whose members are appointed. The island of Nevis enjoys a certain amount of autonomy within the federal structure; it has its own legislature, and the constitution provides for it to secede from the federation if certain procedures are followed. St. Kitts and Nevis have had universal adult suffrage since 1951.

Administration of Nevis

Education is compulsory for all children from the age of five to 16. There are several hospitals and many health centres throughout the islands.

For statistical data on the land and people of Saint Kitts and Nevis, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

Early settlement. Christopher Columbus visited Saint Kitts on his second voyage in 1493 and found it inhabited by Carib Indians. He named it Saint Christopher for his patron saint. The name was shortened to Saint Kitts by settlers under Sir Thomas Warner, who, arriving from England in 1623, established the first successful English colony in the West Indies at Old Road on the west coast. The French also settled on the island in 1627 under Pierre Belain d'Esnambuc. Divided during the 17th century between warring French and English colonists, Saint Kitts was given to Britain by the Treaty of Utrecht in 1713 and remained in British possession despite the capture in 1782 of Brimstone Hill by the French. The island was restored to Great Britain by the Treaty of Versailles in 1783.

Nevis was also sighted by Columbus in 1493. The island's name derives from Columbus' description of the clouds atop Nevis peak as *las nieves*, or "the snows," when he sighted the island. It was settled by the English in 1628 and soon became one of the most prosperous of the Lesser Antilles. Although it suffered from French and Spanish attacks in the 17th and 18th centuries, it remained sound economically until the mid-19th century.

Federation and independence movements. The islands of St. Kitts, Nevis, and Anguilla were united by federal act in 1882 and became an independent state in association with the United Kingdom on Feb. 27, 1967. The islands were granted full internal self-government, with the United Kingdom retaining responsibility for defense and foreign affairs.

After the islands had assumed the status of associated states, Anguilla complained of domination by the Saint Kitts administration. In May 1967 the Anguillans ejected the Saint Kitts police and established their own council. In July of the same year, they proclaimed their independence. After unsuccessful negotiations, the Anguilla Act of July 1971 placed Anguilla directly under British control. On Feb. 10, 1976, Anguilla was granted a constitution and its union with Saint Kitts and Nevis was formally severed in 1980.

Political status of Anguilla

A constitutional conference was held in London in 1982, and Saint Kitts and Nevis became independent on Sept. 19, 1983. In 1998 Nevis narrowly rejected a referendum to secede. The St. Kitts-Nevis Labour Party, which had gained control of the government of the federaton in 1995, retained power after the 2000 elections.   (G.E.M.M./J.D.Mo./Ed.)

For later developments in the history of Saint Kitts and Nevis, see the BRITANNICA BOOK OF THE YEAR.

Saint Lucia

Saint Lucia, an independent parliamentary state within the Commonwealth, is an island of the Lesser Antilles in the Caribbean Sea situated about 24 miles (39 kilometres)

south of Martinique and some 21 miles northeast of Saint Vincent. The capital and major port is Castries. Saint Lucia is 27 miles long and has a maximum width of 14 miles and an area of 238 square miles (616 square kilometres).

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief and drainage.* The island is of volcanic origin and is bisected from north to south by a central ridge of wooded mountains, the highest point being Mount Gimie (3,145 feet [958.6 metres]). Many streams flow from the mountains through fertile valleys. In the southwest are the Gros and Petit peaks (2,619 feet and 2,461 feet), two immense pyramids of rock rising sharply from the sea and enclosing a small bay. Near Petit Peak, in the crater of an ancient volcano, are the boiling sulphur springs from which the nearby town of Soufrière takes its name. A choice tourist site, the springs also contain substantial energy potential.

Plant and animal life. The forest, which has been reduced through lumbering, contains colourful orchids and anthurium. The rich birdlife includes the Saint Lucian parrot (the endangered national bird), the Saint Lucia black finch, and the Saint Lucia oriole. There is also a lizard unique to Saint Lucia, and the agouti is common.

Climate. Saint Lucia lies in the path of the northeastern trade winds and has a tropical maritime climate. Rainfall and temperature vary with elevation. Average annual rainfall ranges from 51 inches (1,295 millimetres) on the coast to as much as 150 inches (3,810 millimetres) in the interior. There is a dry season roughly from January to April and a rainy season from May to November. The mean temperature is about 80° F (27° C), with highs sometimes ranging into the upper 80s and lows into the upper 60s.

The people. No Caribs remain on the island; the vast majority of the inhabitants of the island are black and there is a small minority of mulattoes and other mixtures. The remainder are whites or of East Indian extraction. A French patois is spoken by most of the inhabitants but is being gradually supplanted by English, the official language. The main religion is Roman Catholicism, and Seventh-day Adventists and Anglicans are important minorities. The rate of population growth for Saint Lucia is slightly higher than the Caribbean average. The main population centres are Castries and Vieux Fort.

The economy. *Agriculture, forestry, and fisheries.* Sugarcane was formerly the chief crop, but production ceased entirely in 1964, when most of the cane fields were converted to banana cultivation. Bananas are now the principal crop. Other crops are coconuts, cacao, citrus and other fruit, spices, cassava, and yams. There is a steady local fishing industry.

Industry. Saint Lucia's manufacturing sector has been a major beneficiary of the U.S. Caribbean Basin Initiative, a program designed to promote manufacturing in the region. An industrial free zone has been established in the south of the island near Vieux Fort; there factories produce and export electronic goods and toys. Other industries produce cardboard cartons, clothing, rum, tobacco products, coconut products, concrete blocks, and beer. Tourism has developed rapidly since 1970; in 1987 a complex for cruise ships was opened near Castries.

Trade. The chief exports are bananas, cardboard cartons, clothing, coconut products, and electronic goods. Almost three-fourths of Saint Lucia's exports are to the United Kingdom and most of the rest to other Caribbean islands and to the United States. Imports include food, fuels, and manufactured goods.

Transportation. There is an international airport at Vieux Fort, at the southern tip of the island, and a smaller airport at Vigie for domestic and regional flights. International shipping lines operate from the ports at Castries and Vieux Fort. In addition, there is an oil transshipment terminal near Castries.

Administration and social conditions. *Government.* Saint Lucia is a constitutional monarchy with the British monarch as head of state, represented by a governor-general. The bicameral parliament consists of the House of Assembly elected by universal adult suffrage and the Senate, with members appointed on the advice of the

prime minister, on the advice of the opposition leader in the House, and by the governor-general. The prime minister, leader of the majority party, heads the government. — Head of government

Justice. Saint Lucia has retained its association with the Eastern Caribbean Supreme Court, consisting of a court of appeal and a high court.

Education. Primary education is free and compulsory, and there is a branch of the University of the West Indies at Castries. There is also a technical college and a teacher-training college. Many of the primary schools are parochial, principally Roman Catholic.

Health and welfare. Several general hospitals and many health centres are distributed throughout the island. There is also a private hospital operated by a religious order at Vieux Fort.

Communications. Several newspapers are published on the island, and radio and television broadcasts are widely received.

For statistical data on the land and people of Saint Lucia, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

French and British territorial rivalry. The exact date of the European discovery of Saint Lucia is not known, but it is thought to have been about 1500. The first attempts at colonization were made by the English in 1605 and 1638, but they were frustrated by sickness and the hostility of the native Caribs. A successful settlement was achieved in 1650 by French from Martinique, who made a treaty with the Caribs in 1660. In 1664 Thomas Warner, son of the governor of Saint Kitts, regained the island, but it was restored to France by the Peace of Breda in 1667. In 1674 it was claimed by the crown of France and made a dependency of Martinique.

Another British settlement under a grant made in 1722 by George I to the Duke of Montague was frustrated by France, which had granted the island to Marshal d'Estrées in 1718, and the island was declared neutral. In 1743 the French resumed possession, retaining the island until the Treaty of Aix-la-Chapelle in 1748, in which the two countries again agreed to regard Saint Lucia as neutral. In 1762 it was captured by Admiral George Rodney and General Robert Monckton, only to be given up once more by the Treaty of Paris (1763). In 1778 it again surrendered to the British, who used its harbours as a naval base, but, by the Peace of Versailles, Saint Lucia was once more restored to France. Between 1782 and 1803 the possession of Saint Lucia passed several times between Britain and France, the British having to suppress a vigorous revolutionary party, which was aided by insurgent slaves, before gaining possession in 1803. Saint Lucia was finally ceded to Britain in 1814 by the Treaty of Paris, after which it became a crown colony. During 1838–85, together with the other islands of the Windward group, it was administered by the governor of Barbados. — Cessation to Britain

French influence on the development of Saint Lucia is illustrated by the dominance of the Roman Catholic church and the survival of a French patois. In the years following 1763, French planters came from Saint Vincent and Grenada and established cotton and sugar plantations. In 1834, when the slaves were emancipated, there were in Saint Lucia more than 13,000 black slaves, 2,600 free blacks, and 2,300 whites. Prosperity was impeded by the decline of the sugarcane industry. Improvement came with the increase of banana and cacao cultivation and the revival of sugarcane.

Independence. Representative government was obtained by the constitution of 1924, which introduced an elective element into the legislative council; the constitution of 1936 provided for an unofficial majority in the council.

In 1958 Saint Lucia joined the West Indies Federation, although its colonial status remained unchanged. Under the 1960 constitution the post of governor of the Windward Islands was abolished, and Saint Lucia became an autonomous unit within the federation, also achieving a greater degree of internal self-government. After the federation was dissolved on May 31, 1962, the status question was eventually settled by the West Indies Act of 1967, in

which Saint Lucia assumed a status of association with the United Kingdom on March 1, 1967.

Independence was finally achieved Feb. 22, 1979, with Saint Lucia remaining a parliamentary democracy within the Commonwealth. In the first elections following independence, the left-leaning Saint Lucia Labour Party (SLP) defeated the more conservative United Workers' Party (UWP). The SLP governments favoured the socialist regimes of the Caribbean, establishing relations with Cuba and joining the nonaligned movement. They also helped form the Organization of East Caribbean States in 1981.

The SLP's attempts at a mixed economy proved unable to deal with the staggering problems of the new country, especially after Hurricane Allen wiped out the banana crop in 1980. Rivalry within the party led to the resignation of two prime ministers in two years, and political instability caused the tourist trade to drop to one-half of its pre-independence level. In May 1982 the UWP was voted into power on a platform of inviting foreign investment and decentralizing government administration. The agricultural sector was gradually rebuilt after the hurricane, and the end of a recession in the United States increased tourism. The UWP retained power in elections held in 1987 and 1992.   (R.To./D.L.N./J.D.Mo.)

For later developments in the history of Saint Lucia, see the BRITANNICA BOOK OF THE YEAR.

Marginal note: Hurricane Allen

Saint Vincent and the Grenadines

Saint Vincent and its associated islands of the northern Grenadines form a constitutional monarchy within the Commonwealth. It is part of the Lesser Antilles in the Caribbean Sea, about 21 miles (34 kilometres) southwest of Saint Lucia and 100 miles west of Barbados. Saint Vincent is 18 miles long and has a maximum width of 11 miles, and its area is 134 square miles (347 square kilometres). Some of the larger islands of the Grenadines are Bequia, Canouan, Mayreau, Mustique, and Union Island. Including the Grenadines, the territory comprises a total area of about 150 square miles. The capital and major port is Kingstown, on Saint Vincent.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief, soils, and drainage.* The island of Saint Vincent has thickly wooded volcanic mountains running north to south and producing many short, swift streams. The streams are numerous but, except after heavy rains, small. There are no navigable rivers. The highest peak is the volcano Soufrière (4,048 feet [1,234 metres]) in the north, which erupted disastrously in 1812 and 1902, when the entire northern half of the island was devastated. The 1902 eruption coincided with that of Mount Pelée in Martinique. Soufrière became active again in 1979, causing massive evacuation and a great deal of damage to agriculture. The volcanic ash has produced a fertile soil that has given rise to a lush green vegetation. Birdlife on the island is especially rich. Some of the larger Grenadines have hills, and many are noted for their coral reefs and fine beaches.

Marginal note: The Soufrière volcano

Climate. Saint Vincent lies in the path of the northeast trade winds and has a tropical maritime climate. Rainfall and temperature vary with altitude. Average annual rainfall ranges from about 60 inches (1,524 millimetres) on the coast to 150 inches in the central mountains. The temperature at Kingstown averages between 64° and 90° F (18° and 32° C). Hurricanes occasionally pass across the island, and it suffered severely in 1780, 1898, and 1980. The dry season on St. Vincent lasts from January to May; the rains start in June and continue from that time to the end of the year.

The people. Nearly three-fourths of the inhabitants are black, and another fifth is mulatto. A small minority is of European descent, and there is a small group of East Indian extraction; only a few are of Carib Amerindian stock, but there is a small group of black-Amerindian mixture. English is the official language, and some French patois is spoken. The main religious denominations are Anglican, Methodist, and Roman Catholic. Saint Vincent and the Grenadines has one of the highest birth rates among the West Indies, giving the islands an extremely high rate of population increase that is moderated by emigration.

The economy. *Agriculture, forestry, and fisheries.* The economy of Saint Vincent is chiefly agricultural. Traditional crops are arrowroot (of which the country is a major producer) and sugarcane, but since the 1950s bananas have become the leading export and the production of sugarcane has become negligible. Other crops include sweet potatoes, plantains, yams, ginger, and nutmeg. Nearly half of the island is forested, the woodland being used for charcoal burning. Both inshore and offshore fishing are carried on.

Industry and trade. Industry is based primarily on the processing of agricultural products. Soap and edible oils are produced, and there are also plants for processing copra, distilling rum, milling flour, building yachts, and making boxes for packing bananas. Tourism has assumed a larger role in the economy, but the small number of beaches and the inaccessibility of the Grenadines restrict development.

Marginal note: Development of tourism

The main exports are bananas, root crops, sweet potatoes, flour, and plantains. Carrots are exported to Trinidad and Tobago and Barbados, and plantains are also exported to Barbados. The country's main trading partners include the United Kingdom, Trinidad and Tobago, the United States, and Canada.

Transportation. The major airport is at Arnos Vale, southeast of Kingstown. Three of the Grenadines have airstrips for light aircraft. Kingstown has a deepwater port.

Administration and social conditions. *Government.* The British monarch is the head of state and is represented on the island by an appointed governor-general. The unicameral legislature is composed of the House of Assembly, containing elected representatives and senators appointed by the governor-general. The prime minister, leader of the majority party, is appointed by the governor-general to lead the government.

Justice. Saint Vincent retains its connection with the Eastern Caribbean Supreme Court. This consists of an appeals court and a high court, while the final court of appeal remains the judicial committee of the privy council.

Education, health, and welfare. Primary education is free but not compulsory. Secondary education is conducted mostly in schools administered by religious organizations. Health measures are directed primarily against infant malnutrition and gastroenteritis. The islands have a general hospital and several health centres.

Culture and recreation. The government runs a free public library system, and there is a weekly newspaper. Kingstown has a botanical garden. The Grenadines are particularly known for sailing.

For statistical data on the land and people of Saint Vincent and the Grenadines, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

Colonization. Saint Vincent may have been given its name by Christopher Columbus, who is thought to have visited the island on Jan. 22, 1498 (St. Vincent's Day). Its Carib inhabitants were left almost undisturbed until the 18th century. In 1673 the first Africans arrived, a party of slaves who were shipwrecked in the Grenadines and eventually reached Saint Vincent, intermarrying with the native Caribs. French, Dutch, and British settlements were attempted, with the French dominant until the Seven Years' War, when the British general Robert Monckton occupied it (1762). The Treaty of Paris (1763) confirmed British possession, and settlement proceeded in spite of Carib refusal to accept British sovereignty. In 1779 the island was seized by the French, but it was restored to Britain in 1783. In 1795 the Caribs rose in revolt, assisted by the French, but they were finally subdued the following year. Most of them were then deported to the Bay Islands off Honduras and Belize. The emancipation of black slaves in 1834 decreased the island's labour supply, and Portuguese and East Indian labourers were introduced late in the century.

Marginal note: The arrival of Africans

In the latter half of the 19th century, sugar prices fell, plunging the island into a depression that lasted through

the end of the century. The hurricane of 1898 and the volcanic eruption of 1902 hindered recovery.

In 1958 Saint Vincent joined the West Indies Federation. In 1960 it received a new constitution. It became a state in association with the United Kingdom on Oct. 27, 1969. The island had become a member of the Caribbean Free Trade Area on July 1, 1968.

Independence. Plans put forward in 1972 for the unifications of Saint Vincent with Grenada and Saint Lucia were later dissolved. Independence for Saint Vincent and the Grenadines, as the nation was called, was achieved on Oct. 27, 1979. The new government was formed as a constitutional monarchy and became a member of the Commonwealth. The Saint Vincent Labour Party won the elections of December 1979, and Milton Cato became the first prime minister. Cato was critical of the revolution in Grenada and of developments in Jamaica and Guyana. He preferred closer links with the relatively centrist governments of Trinidad and Tobago and of Barbados.

In 1979 the Soufrière volcano erupted once again, damaging agriculture and the tourist trade. Hurricane Allen virtually wiped out the all-important banana crop in 1980. Recession in the United States and the falling value of the pound sterling against the dollar further lowered tourist visits and exports of bananas.

In July 1984 the New Democratic Party, under James Mitchell, won the general elections. Mitchell began a program of reorganizing agriculture and of lowering unemployment (which stood at more than 30 percent) by encouraging the construction industry. Under his leadership the economy steadily improved, though high unemployment remained a serious problem. Mitchell began a second five-year term in 1989 after elections gave his party all 15 elective seats in the legislature.   (R.To./D.L.N./Ed.)

For later developments in the history of Saint Vincent and the Grenadines, see the BRITANNICA BOOK OF THE YEAR.

Virgin Islands

The Virgin Islands are a group of about 90 small islands, islets, cays, and rocks in the West Indies, situated some 40 to 50 miles (64 to 80 kilometres) east of Puerto Rico. The islands extend from west to east for about 60 miles and are located west of the Anegada Passage, a major channel connecting the Atlantic Ocean and the Caribbean Sea. Their combined land area is about 195 square miles (505 square kilometres).

British and U.S. groups

The islands are administered in two groups—the British Virgin Islands and the Virgin Islands of the United States. The former is a British colony consisting of four larger and 32 smaller islands and islets. Their total area is 59 square miles, and they lie to the north and east of the U.S. islands. The latter group, administered by the U.S. Department of the Interior as an incorporated territory, consists of three larger islands and some 50 smaller islets and cays, with a total area of 133 square miles.

The Virgin Islands are noted for their inviting subtropical climate, which attracts a large number of tourists each year to swim in the warm aquamarine waters and frequent the sandy beaches and harbours. Apart from the tourist industry, the islands have few economic resources; financial aid is provided by the United Kingdom and the United States, respectively. Fresh water is scarce. In recent years some tension has arisen between the inhabitants of the islands and people from other parts of the Caribbean who have immigrated, particularly to the Virgin Islands of the United States, to seek jobs and secure better living conditions.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Although the Virgin Islands form the easternmost extension of the Greater Antilles, they are often included in discussions of the Lesser Antilles because of their size and proximity to that island chain. The Virgin Islands themselves are the peaks of submerged mountains that rise from a submarine plateau. While the Caribbean deepens to a 15,000-foot trench between the island of St. Croix, to the south, and the rest of the group

to the north, the greater part of the plateau is covered by at most 165 feet of water. Most of the islands rise only to a few hundred feet above sea level, although isolated peaks are well over 1,200 feet. The highest point is Mount Sage on Tortola, which is 1,710 feet (521 metres) high.

The principal islands

Of the 36 British islands, 16 are inhabited. Tortola (Turtle Dove), with an area of 21 square miles, is the largest and is the site of the group's capital and population centre, Road Town. Other larger islands in the British group are Anegada, with an area of 15 square miles; Virgin Gorda (the Fat Virgin), with an area of 8 square miles; and Jost Van Dyke, about 3 square miles. Lesser islands include Great Tobago, Salt, Peter, Cooper, Norman, Guana, Beef, Great Thatch, Little Thatch, and Marina Cay.

About 50 islands and cays constitute the U.S. group. Only three are of importance; several are uninhabited. The largest, St. Croix, is 28 miles long, 84 square miles in area, and lies about 40 miles south of the other islands. The island of St. Thomas, 32 square miles in area, is the site of the territory's capital, Charlotte Amalie. St. John has an area of 20 square miles. At the closest point, between Great Thatch Island and St. John, a distance of only half a mile separates the British and the U.S. groups.

The landscape of the islands offers scenes of dramatic contrast, varying from craggy cliffs and mountaintops to small lagoons with coral reefs and barrier beaches, from landlocked harbours to unprotected bays, and from small, level plains to elevated plateaus with rolling lands and junglelike regions. Individual islands have their own distinguishing characteristics.

In the British group, Tortola, of the same geologic formation as St. John, is hilly, with unbroken ranges running throughout its 15-mile length. Road Bay is Tortola's most important bay; it is exposed to the southeast but protected from all other sides by an amphitheatre of hills. Virgin Gorda, an island with several peninsulas, is rectangular in shape, about $2\frac{1}{2}$ miles long, and $1\frac{3}{4}$ miles wide in the central part of the island. Its highest peak rises 1,359 feet. Anegada is the only flat island of the group. Its elevation is never more than 10 to 15 feet above sea level, and its coast, because of its many reefs, is dangerous to boats. Jost Van Dyke is a hilly, almost rugged island with two fine beaches on the south side.

St. Thomas

In the U.S. group, St. Thomas, composed primarily of a ridge of hills running east and west with branching spurs, has little level, tillable land. Crown Mountain (1,556 feet), northwest of the capital of Charlotte Amalie, is the island's highest elevation. Charlotte Amalie, facing a fine landlocked harbour, is built on five foothills. There are a number of springs on the island's northern side but only one small stream. Magens Bay, with 3,500 feet of white sandy beach, is reputed to be the finest beach in the West Indies. St. Thomas is surrounded by 17 islands and by cays and innumerable rocks.

St. Croix rises abruptly on the north to Mount Eagle (1,088 feet) and Blue Mountain (1,096 feet), but southward the land slopes to flatlands that near the coast are laced with lagoons. The island's only urban centres, Christiansted and Frederiksted, lie on the flat land. Since the coastal indentations are slight, there are few harbours and sheltered bays; dangerous reefs lie along the north and south coasts. While there are several rivulets on the island, it is generally poorly watered.

St. John—three miles east across Pillsbury Sound from St. Thomas and lying closest to the British Virgin Islands—has steep, lofty hills and valleys but little level, tillable land. Its highest elevations are Camelberg Peak (1,193 feet) and Bordeaux Mountain (1,277 feet). Its coastline is indented with forests and many fine, sheltered bays. Coral Bay, on the eastern end, whose steep shores allow large vessels to come close in, has been described as the best natural harbour in the Virgin Islands. A number of small streams on the south side of St. John, together with a multitude of springs, make it the best-watered island of the U.S. group. More than three-quarters of its area, about 14,700 acres (5,949 hectares; including Hassel Island in St. Thomas harbour), is preserved as Virgin Islands National Park.

Climate. The splendid climate is perhaps the Virgin Islands' chief asset. Although they are located in the tropics,

the heat is tempered by gentle trade winds that blow from the northeast most of the year. Humidity is low, and there is little pollen. The temperature rarely exceeds 90° F (32° C) or falls below 70° F (21° C). The average temperature is about 78° F (26° C). The dry season lasts from February to July, and the wet season from September to December. Hurricanes—averaging perhaps four in a century—occur usually between August and October, and there are occasional light earthquakes.

Rainfall   The water scarcity is so serious that nearly all buildings, both private and public, have their own water catchments. Rainfall averages between 45 and 50 inches (1,143 and 1,270 millimetres) a year, but much of it runs off unused. In the driest sections of the large islands, rainfall usually averages a little less than 30 inches, with possibly as much as 80 inches on the upper slopes of Mount Sage on Tortola. But rainfall is erratic, varying widely from year to year.

Virgin Islanders have long depended almost entirely upon their own cisterns and wells and, in addition, have imported water in barges to meet their needs for fresh water—needs now rapidly increasing in proportion to population and industrial growth. Only Road Town in the British group has a piped supply. The first flash-type evaporator for the desalination of seawater in the Western Hemisphere was installed in St. Thomas, where the Virgin Islands Water and Power Authority, established in 1965, now operates several saltwater-distillation plants. A seawater desalination plant is located in Christiansted on St. Croix. Maximum use of salt water is made everywhere in the islands.

Plant and animal life. Vegetation is tropical. Supported in most places by thin soil, it includes royal poinciana (flamboyant) trees and other lush blooms, but the islands' generally sparse stands of shrubs and trees are not sufficient to be of commercial value. Among the tree species are mangoes, soursop (a small tropical tree with a large succulent fruit), coconut palms, and breadfruit. Cacao and wild orchids grow in the hills, while cactus, acacia, grass, and sugarcane flourish in the lowlands. Even though the woodlands are not dense, there are numerous species of birds and small game, such as deer. Sailfish, tarpon, marlin, kingfish, and wahoo abound in coastal and offshore waters.

The people. The population is overwhelmingly made up of blacks descended from African slaves. The number of Puerto Ricans and persons from the continental United States has increased in recent years. Less than half of the U.S. Virgin Islands population is native-born.

Despite a long tradition of racial equality and the absence of legal or de facto discrimination in housing, churches, theatres, and public facilities, there have been growing signs of discontent with a type of class discrimination that to a great extent corresponds with the difference between white and black. While there has been relatively little racial violence, there is an increasing demand by those of African descent for a greater role in determining economic and social decisions and in running the government.

The   The Chachas of St. Thomas form a distinct ethnic unit
Chachas   apart from the other islanders. They are descended from French Huguenots who a century ago came from Saint-Barthélémy—a West Indian island the French purchased from Sweden in 1877, after holding it themselves from 1648 to 1784. The Chachas maintain themselves as a clannish, aloof, industrious, fisher–farmer community.

The traditional language of the islands is English—much of it spoken in a dialect termed Calypso, which varies somewhat from island to island but is mutually intelligible among most West Indians. Some French is heard on St. Thomas, and there are numerous Spanish-speaking people on St. Croix, where many Puerto Ricans have settled.

Religious freedom has existed since the 1600s. The islands are predominantly Protestant, the largest denomination in the British Virgin Islands being Methodist and in the U.S. islands, Anglican. The second oldest Lutheran church in the Western Hemisphere held its first service in Charlotte Amalie in 1666, and the second oldest American synagogue is in St. Thomas. Roman Catholics form a large minority in the U.S. islands.

The British and U.S. components of the Virgin Islands differ demographically. The U.S. islands have about nine times the population of their British neighbours; the British islands have the lower birth rate, while the U.S. islands have a greater rate of natural population increase. The death rates for both entities are lower than the Caribbean mean. Both island groups have rates of total population growth that are affected substantially by immigration. The principle urban places are Road Town on Tortola and Charlotte Amalie on St. Thomas.

The economy (British Virgin Islands). Despite the colony's small size, British Virgin Islanders have a fairly high standard of living for the Caribbean region. The economy is based largely on tourism. The U.S. dollar is used as the official currency.

Agriculture. Despite the handicaps of difficult terrain and uncertain water supply, agriculture and stock raising (largely for export to the U.S. Virgin Islands) are undertaken. Farms are usually small holdings worked by owner-occupiers, many of whom are also part-time fishermen. The chief crops are fruits, vegetables, and coconuts for both domestic use and export; sugarcane is grown for the distillation of rum. Many of the younger people seek work in the U.S. islands, where wages are higher.

Industry. The tourist industry makes up almost half of the national economy. New roads have been built, harbours improved, and tourist hotels built. The number of tourists visiting the islands, attracted by opportunities for sport fishing and sailing, has continued to increase.

Burning wood for charcoal is a minor industry, and there are several boatyards for the construction and repair of vessels. Cement blocks and rum are manufactured.

Trade. Imports—mostly from the United States, Puerto Rico, and the United Kingdom—consist chiefly of foodstuffs, beverages, machinery, motor vehicles, building materials, and petroleum products. Exports, mainly to the U.S. Virgin Islands, include fresh fish, rum, sand and gravel, charcoal, fruit, and vegetables.

Transportation. Tortola has two main highways and numerous side routes; Virgin Gorda, Anegada, and Jost Van Dyke also have road networks. Small boats ply to and from the U.S. Virgin Islands. An airport, reconstructed in 1969, is located on Beef Island, which is connected by bridge to Tortola. Another airport, on Anegada, was opened in 1969, and there is plane service to the U.S. Virgin Islands, Puerto Rico, and Antigua. Road Harbour on Tortola is a deepwater port.

The economy (U.S. Virgin Islands). Until well into the   Sources of
20th century, sugarcane and, to a lesser extent, cotton   income
provided the main economic base. The harbour at St. Thomas also generated some income. When the United States acquired the islands, both social and economic conditions were poor. The first U.S. governor reported in 1917 that the islands were incapable of self-support. Since then, millions of dollars of U.S. aid have failed to make them self-supporting. U.S. aid and the development of tourism have nevertheless resulted in the territory's having one of the highest incomes per capita in the Caribbean.

Resources. Minerals of commercial value do not exist, although sand, rock, and gravel are present in quantities sufficient for construction purposes.

Fisheries. There is no large commercial fishing industry, but fish represent an important part of the islanders' diet, and there is a shellfish-farming operation on St. Croix. Tourism has encouraged sport fishing.

Industry. As in the British Virgin Islands, tourism is the most important economic sector. In the U.S. islands there are more than 200 miles of beaches, several historic 17th- and 18th-century buildings, pleasant vistas of mountain and sea, and numerous recreational facilities. The picturesque free port of Charlotte Amalie is also an attraction. Small manufacturing operations, including watch making, textile manufacturing, rum distilling, and pharmaceutical production, have been encouraged, as have some larger ones. One of the world's largest oil refineries is located on St. Croix, and petroleum products are the islands' leading export. Tax concessions were granted by the United States in 1987 to encourage manufacturing.

Trade. The U.S. islands depend heavily on imports for

their survival—most importantly crude oil for the large refinery. Food is the next most important import. Other than refined petroleum, exports include chemical products, watches and watch movements, and rum. The main trading partner is the United States.

Transportation. The U.S. islands have a fairly good road network. Taxis and rental vehicles are available on all three islands, and regular passenger-bus services operate on St. Croix and St. Thomas. Interisland transport by small boat is available. Seagoing passenger and cargo vessels connect the ports of Charlotte Amalie, on St. Thomas, Frederiksted and Limetree Bay, on St. Croix, to ports abroad. International jet air services operate on St. Thomas and St. Croix.

Administration and social conditions (British Virgin Islands). *Government.* The islands are a crown colony with a governor, appointed by the British crown, who is responsible for defense and internal security, external affairs, and the civil service. He exercises his powers in consultation with the Executive Council, over which he presides. The council consists of three ministers plus the chief minister and the attorney general. The Legislative Council consists of one ex officio member (the attorney general), nine members elected by universal adult suffrage, a speaker, who is elected from outside the council by its members, and one member appointed by the governor.

The Executive Council

Justice. The law of the colony is made up of both the common law of England and statutory law, or locally enacted legislation. It is administered by the Eastern Caribbean Supreme Court, courts of summary jurisdiction, and magistrates' courts. The principal law officer is the attorney general.

Education and health. Education is compulsory and free, but there is a shortage of schools. The islands have several private schools, but there are no institutions of higher learning. Health conditions are fairly good. The administration carries out a regular immunization program, and there is a modernized hospital on Tortola. A program of social welfare has also been implemented.

Administration and social conditions (U.S. Virgin Islands). *Government.* Jurisdiction is exercised by the U.S. Department of the Interior. Limited legislative powers are held by a unicameral legislature consisting of 15 senators, each elected by popular vote for two-year terms. The governor and lieutenant governor are also elected by universal adult suffrage. There are 12 executive departments, of which 11 are headed by commissioners; the 12th, the Department of Law, is headed by the attorney general. Attempts to redraft the constitution to provide greater autonomy have been rejected, most recently in 1981. Residents of the Virgin Islands do not vote in U.S. presidential elections. They are represented in the U.S. House of Representatives by a nonvoting delegate.

Justice. Judicial power in the islands resides in municipal courts and in the Federal District Court of the Virgin Islands. The district judge and the district attorney are appointed by the president of the United States, with the advice and consent of the U.S. Senate. Municipal court judges are appointed by the governor, subject to confirmation by the legislature.

Education and health. Education is compulsory and free, but many students attend private schools. The University of the Virgin Islands (established in 1962) has campuses on both St. Thomas and St. Croix. Health services are more extensive in the U.S. than in the British islands. There is a large general hospital on St. Thomas, and hospital services are available on the other two large islands. Mobile units reach the outlying islands.

Cultural life. The Virgin Islands have little in the way of a national culture. There is no typical music and little folklore. In 1965, however, the Virgin Islands Council of the Arts was created as an adjunct of the U.S. National Foundation on the Arts and Humanities. Community arts councils have been formed on all three American islands. They sponsor theatrical performances and provide training in the arts and crafts.

For statistical data on the land and people of the U.S. Virgin Islands, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

Pre-Columbian inhabitants of the islands probably included the Arawak, who were displaced by the Caribs; the latter had reached the stage of stone polishing and pottery making when Christopher Columbus arrived. On his second voyage, in 1493, Columbus dropped anchor at what is now known as Salt River Bay, St. Croix (which he called Santa Cruz), and sent a landing party ashore in search of fresh water and fruit. After a skirmish, the Caribs repulsed the Spanish. Columbus later encountered some of the other islands and named the group Santa Ursula y las Once Mil Virgenes (St. Ursula and the Eleven Thousand Virgins). In 1555 the Holy Roman emperor, Charles V (Charles I of Spain), sent forces that defeated the Caribs, claimed the territory, and ordered the annihilation of the natives. By 1596 most of the natives had been killed or had left.

Settlement and history of the British Virgin Islands. Tortola was first settled in 1648 by Dutch buccaneers who held the island until it was taken over in 1666 by a group of English planters. In 1672 Tortola was annexed to the British-administered Leeward Islands. In 1773 the planters were granted civil government, with an elected House of Assembly and a partly elected Legislative Council, and constitutional courts. The abolition of slavery in the first half of the 19th century dealt a heavy blow to the agricultural economy. In 1867 the constitution was surrendered and a legislative council was appointed that lasted until 1902, when sole legislative authority was vested in the governor-in-council. In 1950 a partly elected and partly nominated legislative council was reinstated. Following the defederation of the Leeward Islands colony in 1956 and the abolition of the office of governor in 1960, the islands became a crown colony. In 1958 the West Indies Federation was established, but the British Virgin Islands declined to join, in order to retain close economic ties with the U.S. islands. Under a constitutional order issued in 1967, the islands were given a ministerial form of government. The constitution was amended in 1977 to permit a greater degree of autonomy in internal affairs.

Settlement and history of the U.S. Virgin Islands. In 1666 St. Thomas was occupied by Denmark, which five years later founded a colony there to supply the mother country with sugar, cotton, indigo, and other products. Slaves from Africa were first introduced to St. Thomas in 1673 to work the cane fields, but the first regular consignment of slaves did not arrive until 1681. In 1684 the Danes claimed neighbouring St. John, which had been used primarily as a base by buccaneers. Denmark colonized the island with planters from St. Thomas in 1717. In 1733 they abandoned St. John after slaves rebelled, staged an uprising, and held the island for six months. They then purchased St. Croix, which had been in the possession of the French since 1651. Slaves continued to be imported from Africa; by 1742 there were 1,900 on St. Croix alone, and sugar production was bringing prosperity to the islands. The group came under the Danish crown in 1754, and the following year Charlotte Amalie was made a free port. The British occupied the islands from 1801 to 1802, and in the next year, 1803, the slave trade was abolished in the Danish West Indies. The British reoccupied the islands from 1807 to 1815, after which they reverted to Danish rule until 1917. Slavery itself was abolished in 1848 after a serious uprising in that year. Sugarcane production dropped, and there was a general decline in economic activity.

The Danish era

U.S. interest in the islands began in the Civil War period, but the U.S. Senate refused in 1870 to approve the purchase of St. Thomas and St. John for $7.5 million. The United States moved decisively only in World War I, when it was seen to be strategically important to control the main passage through the Caribbean to the Panama Canal, as well as routes along the eastern coasts of the American continent. Denmark at that time was willing to sell to avoid the jeopardy of seizure by the Allies or conquest by Germany, which then owned Hamburg–America Line docks, warehouses, steamers, and other property in St. Thomas. In 1917 the United States purchased the three islands for $25 million and the Virgin Islands became an

unincorporated territory of the United States. The treaty of cession promised U.S. citizenship to the inhabitants, except for those who chose to retain Danish citizenship.

An act in 1927 granted U.S. citizenship to most of the Virgin Islanders, and another in 1932 provided that all natives of the Virgin Islands who on the date of the act were residing in the continental United States or any of its insular possessions or territories were U.S. citizens. The transition was accomplished smoothly by retaining the organization of the Danish government and its legal code. All military, civil, and judicial power was invested in a governor appointed by the president of the United States. Administration was the responsibility of the U.S. Navy Department from 1917 until 1931, when jurisdiction was transferred to the Department of the Interior.

The Organic Act of 1936, enacted by the U.S. Congress for the establishment of congressional government, provided for two municipal councils, one for St. Thomas and St. John, the other for St. Croix, and a council for the whole territory. A Revised Organic Act adopted in 1954 created a central government and abolished the independent municipal councils, authorized distinct executive, legislative, and judicial branches, and provided for a substantial degree of self-government. In 1968 an act was approved, which took effect in 1970, legalizing the popular election of the islands' governor and lieutenant governor for four-year terms.

There has been little demand for autonomy by either the British or U.S. Virgin Islands, mostly because of fears of disrupting the lucrative tourist industry and of incurring an increased tax burden. Independence appears not to be the goal for either territory, and statehood continues to be only a remote possibility for the U.S. islands. The inability of either territory to develop a self-supporting economy continues to encourage their dependent status. In 1995 a major hurricane struck the islands, devastating the economy. (L.H.E./Ed.)

For later developments in the history of the U.S. and British Virgin Islands, see the BRITANNICA BOOK OF THE YEAR.

OTHER ISLANDS

Aruba

The island of Aruba lies southwest of the Lesser Antilles in the Caribbean Sea, some 50 miles (80 kilometres) northwest of Curaçao and 18 miles north of the Venezuelan peninsula of Paraguaná. Politically a part of the Netherlands Antilles until 1986, Aruba in that year became a separate self-governing part of the Kingdom of The Netherlands. Its capital and main port is Oranjestad.

PHYSICAL AND HUMAN GEOGRAPHY

The land. Aruba, with an area of 75 square miles (193 square kilometres), is 19.6 miles long and 6 miles across at its widest point. The island is generally low in altitude and consists of igneous rocks, fringed with coral reefs. The 620-foot (189-metre) Mount Jamanota is the highest point and the 560-foot monadnock Mount Hooiberg ("Haystack") the most characteristic hill. In some places immense monolithic boulders of diarite are peculiarly piled on top of one another. Aruba has barren soil with little or no natural irrigation. Most drinking water is obtained by desalinating seawater. The temperature varies little from an annual average of 81° F (27° C), and the heat is tempered by northeasterly trade winds. Rainfall is low and variable, usually amounting to about 17 inches (430 millimetres) a year. The island lies outside the usual path of hurricanes. The natural vegetation consists of a variety of drought-resistant cacti, shrubs, and trees.

The people. Most of Aruba's population is racially mixed, including a considerable percentage of American Indian stock, often in combination with Dutch, Spanish, and African strains. The black influence is minimal, however, few slaves having been imported to Aruba. The official language is Dutch, but the common language is Papiamento, a creole that evolved mainly from Portuguese, Spanish, and Dutch. English and Spanish are also widely used. The major religion is Roman Catholicism. The birth and death rates are both relatively low, and the rate of natural increase is less than average for the West Indies.

The economy. Until the end of the 18th century, Aruba was used by the colonial authorities for horse breeding, the local and mainland Indians serving as herdsmen. Only from the early 19th century on was land sold to individual settlers. Agriculture remained of little importance despite efforts to grow aloe for pharmaceutical products. Gold mining began in 1824 but was discontinued by the early 20th century. Aruba's economy improved when oil refining started in the 1920s at the port of Sint Nicolaas; crude oil was imported mainly from Venezuela. The closing of the refinery in 1985 provoked a serious economic crisis, which has been overcome by aggressive promotion and expansion of tourism, including the building of luxury hotels and casinos to exploit the idyllic island setting. Attempts to diversify the economy include the develop-ment of a free-trade zone and plans to develop Aruba into an international offshore financial centre. Aruba's foreign trade is mainly with the United States, Venezuela, and The Netherlands. The island has an international airport and is further linked to the outside world by steamship and cruise ship services.

Administration and social conditions. A governor, appointed by the Dutch crown, is the formal head of government and representative of the reigning monarch of The Netherlands. Executive authority is vested in a Council of Ministers, headed by a prime minister. The council is responsible to a unicameral legislature, the Staten (States), elected by universal adult suffrage. Most of the population is literate. All levels of education, including postsecondary, are available. Health standards on the island are high.

Cultural life. The Cultural Center at Oranjestad offers concerts, ballet, folkloric presentations, and art exhibits throughout the year. The city also includes historical, archaeological, and numismatic museums. Carnival time in February and the New Year's Day festivities are especially colourful celebrations. (H.Ho.)

HISTORY

Originally inhabited by Arawak Indians, Aruba was discovered and claimed by Spain in 1499. In 1636 it was taken by the Dutch and occupied by the Dutch West India Company. As part of the Netherlands Antilles, Aruba came briefly under British rule during the Napoleonic Wars but was returned to The Netherlands in 1816.

The economy remained weak until an oil refinery was constructed at Sint Nicolaas in the 1920s, which raised the standard of living dramatically. Immigration from the rest of the Caribbean, the United States, Venezuela, and Europe contributed to a substantial increase in population. Despite its new economic strength, Aruba remained politically subordinated to the main island of Curaçao.

In 1986 Aruba obtained autonomous status, the result of a popular movement led by the Movimento Electoral di Pueblo (People's Electoral Movement) to break away from Curaçaoan—rather than from Dutch—domination. In 1994 the Aruban government, in conjunction with the governments of The Netherlands and the Netherlands Antilles, decided to postpone indefinitely the transition to full independence. (H.Ho./Ed.)

For later developments in the history of Aruba, see the BRITANNICA BOOK OF THE YEAR.

The Bahamas

The Commonwealth of The Bahamas, a former British colony, became an independent nation within the Commonwealth in 1973. The island group comprising The Bahamas (from Spanish *bajamar,* "shallow water") occupies an irregular submarine tableland that rises out of the

[margin notes: Topography; Foreign trade]

Atlantic depths and is separated from nearby lands to the south and west by deepwater channels. Lying to the north of Cuba and Hispaniola, the archipelago comprises nearly 700 islands and cays, only about 30 of which are inhabited, and more than 2,000 low, barren rock formations. It stretches more than 500 miles (800 kilometres) southeasterly from Grand Bahama Island, which lies about 60 miles off the southeastern coast of Florida, to Great Inagua Island, some 50 miles from the eastern tip of Cuba. The total land area is 5,382 square miles (13,939 square kilometres).

Strategic location
The strategic position of the Bahama Islands, which lie at the geographic centre of the New World landmass, commanding the gateway to the Gulf of Mexico, the Caribbean Sea, and the entire Central American region, has given the history of the islands a unique and often striking character. It was there that Christopher Columbus made his original landfall in the Americas. The subsequent fate of the peaceful original inhabitants remains one of the more tragic episodes in the development of the entire region, while the early attempts at European-dominated settlement were marked by intense national rivalries, interspersed with long periods of lawlessness and piracy. As a result, the society and culture that has evolved in The Bahamas is a distinctive blend of European and African heritages, the latter a legacy of the slave trade. The islands, lacking natural resources other than their magnificent climate and dazzling beaches, have become heavily dependent on the income generated by the extensive tourist facilities that have been developed, often as a result of the injection of foreign capital. The continued popularity of the islands, largely with North American tourists, has maintained a relatively high standard of living among the population, most of whom are black.

The capital city, Nassau, is situated on the small (80 square miles) but important New Providence Island. Other islands, known collectively as the Family (or Out) Islands, include Grand Bahama (530 square miles), which contains the major settlements of Freeport and West End; Andros (2,300 square miles), the largest island; Great Abaco (372 square miles); and Eleuthera, site of one of the early attempts at colonization. In spite of the concentration of the population in urban centres (especially Nassau and Freeport) devoted to tourism, the traditional pattern of small farming and fishing prevails in many villages, notably in the southeastern islands.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief and soils.* Extensive areas of flatland, generally a few feet in elevation, are the dominant topographic features of the major islands; Bimini, for example, has an elevation of only 20 feet (six metres). A number of islands fronting the Atlantic have a range or series of ranges of hills on their northeastern side and parallel to the longer axis of the island. These are formed of sand washed ashore and blown inland by the trade winds. The newer hills adjacent to the seashore are normally sand dunes. Solidity increases toward the interior, where the particles become cemented to form Bahama limestone. Eleuthera and Long Island have the greatest number of hills exceeding 100 feet, and the highest point, 206 feet (63 metres), is on Cat Island. Beneath the soil, the islands are composed of the skeletal remains of coral and other marine organisms. There are no rivers, but several islands—particularly New Providence, San Salvador, and Great Inagua—have large lakes.

Temperature and rainfall
Climate. The Bahamian climate, mild throughout the year, is one of the great attractions of the area. The average temperature varies from 70° F (21° C) during the winter to 81° F (27° C) during the summer, and extremes seldom fall below 60° F (16° C) or rise above 90° F (32° C). The average annual rainfall is about 44 inches (1,120 millimetres), occurring mostly during the summer months. Prevailing winds, coming from the northeast in winter and from the southeast in summer, lend a cooling influence to a generally humid atmosphere. Hurricanes present something of a threat during the period from mid-July to mid-November and have occasionally caused great destruction.

Plant and animal life. Extensive and beautiful forests of Caribbean pine are found on Grand Bahama, Great Abaco, Andros, and New Providence. Hardwood forests, known locally as "coppices," also occur on some of the islands. Elsewhere, the woody vegetation consists mostly of shrubs and low trees. Animal life is dominated by frogs, lizards, and snakes, all of them nonpoisonous, and several species of bats are found in caves along the more rocky coasts. Larger animals include the agouti, a rodent; the raccoon; the iguana; and the elegant flamingo, the national bird. All of these have been much reduced in numbers and in distribution. In addition, several animals—notably sheep, horses, and other livestock—have been introduced from Europe. The surrounding waters abound with fish and other edible marine animals, such as conch and crayfish.

Settlement patterns. The centres of population are widely distributed on each island. Some are located to the leeward, where it is calm and sheltered—for example, Cat Island—and others face the north and northeastern sides, where they are exposed to the northeast trade winds—as in the case of the Abaco Cays. Main settlements usually occur where there is a natural harbour or at least accessibility for shipping. There has been a marked shift of population from fishing and farming villages to the centres of tourist and commercial activity. Most of the population movement has been to New Providence, Grand Bahama, and Great Abaco.

Rural to urban migration

The people. A minority of the population is descended from English pioneer settlers and loyalist refugees. Most of the population is of African descent, many with varying amounts of Caucasian blood. There are also minorities of Greeks, Syrians, Haitians, and other West Indians. English is the only language native to Bahamians, although since the influx of Haitian immigrants, French or its creole dialect is spoken.

A high percentage of Bahamians are members of Christian churches. Most are Protestants, the largest denominations being Baptist, Church of God, Anglicans, and Methodists. Roman Catholics form a large minority.

About two-thirds of the Bahamian population is concentrated on New Providence Island, which, with Grand Bahama and Great Abaco, has received the most internal migration. The Bahamas' rate of population increase is much higher than the Caribbean average, primarily because of immigration from the United States and other West Indian islands. The rate of natural population increase is about equal to the Caribbean mean, but both the birth and death rates are less than the average for the West Indies as a whole.

The economy. The major economic activities that sustained The Bahamas until the mid-20th century were farming and fishing. During the latter part of the 19th century, sponge fishing and the production of pineapple and sisal were important. Sponge fishing was the major industry between the 1860s and 1938, but it declined and has been replaced by tourism. Banking has become the second most important industry, and The Bahamas is growing as an international financial centre. Crayfishing contributes significantly to the economy.

Manufacturing industries include food-processing plants (mainly tomato and pineapple canning and crayfish freezing), a petrochemical refinery and a pharmaceutical factory (mainly producing hormones). Freeport has become the most important centre of industrial development and is second only to Nassau in tourist and commercial activity. Salt is produced by solar evaporation at Inagua. Aragonite, a hard, granular limestone used in the manufacture of cement, steel, petrochemicals, glass, and other products, is mined near Sandy Cay. The government has encouraged the development of small industries, and various forms of food production continue at numerous places for domestic consumption. The Bahamas has an open shipping registry, and the merchant fleet sailing under its flag is one of the world's largest. There is no direct taxation, and customs duties produce the major share of revenue.

Transportation. Nassau and Freeport and their environs have modern paved roads, as do most of the inhabited islands. A fleet of small motor vessels carries passengers, freight, and mail weekly between Nassau and the Family

Islands. The deepwater harbours of Nassau and Freeport are dredged to depths of more than 30 feet. Numerous foreign passenger and freight ships visit the two ports each year. The airplane has become of increasing importance to the Bahamian economy. Throughout the islands there are some 60 airports, with varying accommodations and facilities. Most of these serve only interinsular aircraft; but international airports are located at Nassau and Freeport, and international flights also connect with the islands of Great Exuma, Great Abaco, and Eleuthera.

Administration and social conditions. *Government.*
The government is patterned after that of the United Kingdom. Since 1973 the British monarch has appointed the governor-general, who in turn appoints a prime minister. The latter must be a member of the House of Assembly and must be able to command a majority of Assembly votes. The parliament consists of two houses. The House of Assembly is elected by the people; the Senate, which has severely restricted powers, is appointed by the governor, who selects the majority of the members on the advice of the prime minister. The life of the parliament is limited to a maximum of five years, but, if the prime minister is unable to control the Assembly effectively or if he considers it expedient, both bodies are dissolved and reconstituted. Judicial power on the islands resides in the Court of Appeal, the Supreme Court, and magistrates' courts.

Education and health and welfare. There is little illiteracy in The Bahamas. Schooling is compulsory from five to 14 years of age. Public secondary and technical schools have been expanding. The College of The Bahamas, established in 1974 in Nassau, is a community college that offers programs in conjunction with other universities, including the University of the West Indies, Florida International University, and the University of Miami. Bahamians are relatively free of malnutrition and debilitating diseases, and medical problems among children are largely those involving common infections. Increasing alcohol and drug abuse has become a concern, and care for the aged is a mounting problem. Extensive government-sponsored housing developments have alleviated some of the housing problems.

Cultural life. Bahamian culture reflects the origins of its people and has also been influenced by the peoples of nearby islands. Outstanding among traditional group activities is the Junkanoo parade on Boxing Day and New Year's Day in Nassau. The main thoroughfare is given over to hundreds of gaily bedecked celebrants who, with clanging cowbells and beating drums, march and dance to a goombay rhythm of African origin. Island folklore includes stories of a three-toed, human-faced creature called the Chickcharney and the workings of Obeah, a brand of witchcraft. In Nassau, Bahamian drama and art have come into their own. There is a repertory season at the Dundas Centre for the Performing Arts that includes serious drama, musicals, and dancing. Various drama groups also present musicals and drama in the off-season. Works of art can be seen at the various galleries. The National Trust is concerned with the preservation of wildlife and historic buildings, and the Department of Archives preserves public and private records, making them accessible to the public. The Historical Society promotes local history.

For statistical data on the land and people of The Bahamas, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

It is widely held that on Oct. 12, 1492, Christopher Columbus first landed on an island called by its native inhabitants Guanahani, which he renamed San Salvador. Its actual identity is still in dispute, but some scholars believe it is the place known today as Watling Island, while some others claim the first landfall to have been at Samana Cay, or Cat Island. Columbus explored the island and others nearby and then sailed to Cuba and Hispaniola. The natives of the Bahamas, whom Columbus called Lucayans, were Arawak Indians. They also inhabited the Greater Antilles and were peaceful. Between 1492 and 1508, Spanish raiders carried off about 40,000 natives to work in the mines of Hispaniola (Haiti and the Dominican Republic),

and the islands remained depopulated more than a century before the first English settlement took place.

Although Columbus took formal possession of the islands with pomp and ceremony in the name of Spain, and under the Treaty of Tordesillas between Spain and Portugal in 1494 the islands were held to come within the Spanish sphere, the Spanish made little attempt to settle them.

British colonization. British interest began in 1629 when Charles I granted Sir Robert Heath, attorney general of England, territories in America including "Bahama and all other Isles and Islands lying southerly there or neare upon the foresayd continent." Heath made no effort to settle the Bahamas. In the 1640s Bermuda was troubled by religious disputes. In 1647 Captain William Sayle, who had twice been governor of Bermuda, took the leadership of an enterprise to seek an island upon which dissidents could worship as they pleased. In July of that year the Company of Eleutherian Adventurers was formed in London "for the Plantation of the Islands of Eleutheria, formerly called Buhama in America, and the Adjacent Islands." Sayle and about 70 prospective settlers, consisting of Bermuda Independents and some persons who had come from England, sailed from Bermuda for the Bahamas some time before October 1648. The place of their landing is uncertain, but modern belief is that they settled on Eleuthera, then known as Cigatoo. They had envisioned establishing a flourishing plantation colony, but unproductive soil, internal discord, and Spanish interference dashed their hopes. Some of the settlers, including Sayle, returned to Bermuda.

New Providence was first settled in 1656 by a new group of Bermudans. In 1663 South Carolina was granted by Charles II to eight of his friends as lords proprietors, and they appointed Sayle as the first governor. Both Sayle and certain of those who had interested themselves in the settlement of New Providence independently drew the attention of the lords proprietors to the possibilities of the Bahama Islands, and in consequence the Duke of Albemarle and five others acquired a grant of the islands from Charles II in 1670, and they accepted nominal responsibility for the civil government. New Providence, with the largest population, became the seat of government.

The proprietors did not take a very active interest in the settlement or development of the islands, however, and they soon became a haven for pirates, whose depredations against Spanish ships provoked frequent and savage retaliatory raids. In 1671 they appointed John Wentworth as the first governor. Although elaborate instructions for the government of the colony were issued and a parliamentary system of government was instituted, the lot of both governors and settlers was far from easy. New Providence was often overrun by the Spaniards alone or in combination with the French, while any governor attempting to institute a semblance of law and order received short shrift from the settlers, who had found piracy the most lucrative profession. In 1684 the king himself intervened and required that a law be passed against the pirates, but apparently it had little effect.

Early in the 18th century, official representations were being made for direct crown control. The lords proprietors surrendered the civil and military government to the king in 1717 and leased the islands to Captain Woodes Rogers, whom the king commissioned as the first royal governor and charged with the responsibility of exterminating pirates and establishing more stable conditions. When he arrived in 1718, armed with a disciplined troop of soldiers, about 1,000 pirates surrendered and received the king's pardon, while eight of the unrepentant were hanged. His measures were so effective that in 1728 the colony was able to adopt the motto, "Expulsis piratis restituta commercia."

In 1660 the present site of the capital was known as Charles Towne in honour of Charles II, but these early settlers saw fit to change the name to Nassau when William and Mary came to the throne; the German region Nassau was a holding of William's family. With the restoration of order following the establishment of the royal government, the settlers demanded an assembly. In 1729 Woodes Rogers, acting under authority from the crown, issued a proclamation summoning a representative assembly and

Margin notes:
Executive leadership

Colonization by Captain Sayle

Traditional folk activities

Restoration of law and order

from then on, apart from the brief interruptions caused by foreign invasion, the government of the colony carried on in an orderly manner.

In 1776 Nassau was captured by the U.S. Navy, which was seeking supplies during the Revolutionary War; they evacuated after a few days. In May 1782 the colony surrendered to Spain and, though it was restored to Britain by the Peace of Versailles in January 1783, it was brilliantly recaptured in April by Colonel Andrew Devaux, a loyalist commander, before news of the treaty had been received. On the conclusion of the American Revolution many loyalists emigrated from the United States to the Bahamas under very favourable terms offered by the crown. Among the newcomers was Lord Dunmore, formerly governor of New York and of Virginia, who served as governor of the Bahamas from 1786 to 1797. The loyalists fled with their slaves to the islands, doubling the white population and trebling the black. The cotton plantations that they developed yielded well for a few years, but exhausted soil, insect pests, and, finally, abolition of slavery led to their ultimate collapse. In 1787 the proprietors surrendered their remaining rights for £12,000.

Early 19th-century efforts of the assembly to thwart the attempts of the executive to ameliorate the conditions of the slaves continued until the United Kingdom Abolition Act came into force in the colony on Aug. 1, 1834; full emancipation came in 1838. A legislative council was created by royal letters patent in 1841.

Considerable wealth poured into the islands as the result of blockade-running during the American Civil War and the handling of liquor during Prohibition in the 1920s in the United States. This activity made no lasting contribution to the islands, however, nor did it establish any firm economic base. Before and after these periods, many attempts were made to grow pineapples, citrus fruits, tobacco, tomatoes, and sisal for export, but despite initial promise, all failed. Sponge fishing also collapsed in 1938.
Establishment of tourism — After World War II, strenuous efforts to establish tourism as the basis of the economy were strikingly successful, transforming the economic and social structure of the islands.

Independence. Politically, Bahamians have had considerable control over their affairs since the first assembly in 1729. In May 1963 a conference was held in London to consider a new constitution for the islands. It was then agreed that the colony should have full internal self-government, the governor retaining reserved powers only for foreign affairs, defense, and internal security. The new constitution came into force on Jan. 7, 1964, and constitutional advances in 1969 brought the country to the verge of complete self-government.

Party politics emerged in 1953, when the Progressive Liberal Party (PLP) was formed by blacks to oppose the group in power, who in 1958 responded with a party of their own, the white-controlled United Bahamian Party (UBP). As the political battle progressed, the PLP raised the cry for majority rule. The climax came after the general elections of 1967, when the PLP under the leadership of Lynden Pindling was able to form a government with a slight majority. Elections that were held the following year gave that party 29 of the 38 Assembly seats. It is widely believed that the UBP was defeated mainly on the racial issue, but the accusation that that party had introduced criminal-controlled gambling and that some of its members had profited thereby had a telling effect.

In general the PLP advocated stricter government control of the economy, increasing Bahamian ownership of business enterprises and the replacement of foreign workers by Bahamians. Although the move toward self-government received bipartisan support, some factions advocated that total independence should come later than 1973, the target year of the PLP government. In 1969 the name of Commonwealth of the Bahama Islands was adopted, but upon independence, on July 10, 1973, the official form
Dominance of the PLP — became The Commonwealth of The Bahamas. The PLP maintained its position as the majority party after independence. The main opposition was formed by the Free National Movement established in 1972 through a merger of the UBP and alienated anti-independence PLP members. The government embarked on programs to improve economic development, increase the standard of living, and halt the rising unemployment rate. The Bahamas was admitted to the Caribbean Community (Caricom) in July 1983. Alleged drug trafficking in government became a major issue and threatened PLP power in the late 1980s.
(E.P.A./D.R.Ha./D.G.Ss.)

Cayman Islands

Cayman Islands is a British colony in the Caribbean Sea, comprising the islands of Grand Cayman, Little Cayman, and Cayman Brac, situated about 180 miles (290 kilometres) northwest of Jamaica. The islands are the outcroppings of a submarine mountain range that extends northeastward from Belize to Cuba. The total area is 102 square miles (264 square kilometres), and the capital is George Town, on Grand Cayman.

PHYSICAL AND HUMAN GEOGRAPHY

The land. The limestone islands are low-lying, though Cayman Brac has a central bluff that constitutes 90 percent of its landmass. The coasts are ironshore (limestone fringes with numerous marine fossils) interspersed with sandy beaches and enclosed by coral reefs. The largest island is Grand Cayman (76 square miles), which has a magnificent seven-mile beach and a 36-square-mile sound that is a breeding ground for much marine life. There are no rivers.

The Caymans are cool from November to March, with the temperatures ranging from 65° to 75° F (18° to 24° C). Rainfall at George Town averages 60 inches (1,524 millimetres) annually, although the eastern districts of Grand Cayman and the other islands are drier. The Caymans lie in the hurricane zone, and hurricanes can occur from June through November. Quite a few bird species inhabit the islands. — Climate

The people. About one-quarter of Caymanians are of European, mainly British, stock; another quarter are blacks, the descendants of African slaves; and about one-half of the population is of mixed ancestry. English is the official language. Most of the major Christian denominations are represented in the islands.

The economy. The physical beauty and superb climate of the islands have made them a haven for tourists. Airports on Grand Cayman and Cayman Brac and a private airstrip on Little Cayman facilitate tourism. International finance has become a major industry, owing to the absence of direct taxes and to liberal company and banking laws that generally ensure confidential transactions. More than 500 banks and trust companies, including most of the world's 50 largest banks, are registered in the Caymans; revenue paid by registered businesses contributes considerably to the government budget. There is a shortage of labour, and much of the work force is made up of immigrants on tightly controlled work permits.

Administration and social conditions. The 1972 constitution provides for internal autonomy under a governor, an executive council, and a legislative assembly. The governor is responsible for foreign affairs, defense, internal security, the police, and the civil service. Education is compulsory for all children between the ages of four years, nine months and 16.

Cultural life. The F.J. Harquail Theatre on Grand Cayman is the main venue for local and visiting companies. There is a daily newspaper, a government-owned radio station, and a monthly news magazine.

For statistical data on the land and people of the Cayman Islands, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

The Caymans were sighted by Christopher Columbus on May 10, 1503, during his last voyage to the West Indies. At first the Spaniards named them Las Tortugas because of the many turtles in the surrounding waters, but by 1530 they were known as the Caimanas or Caymanes

First
permanent
settlement

after the alligators (*caimánes*) reported to be native there. After the Treaty of Madrid that ceded Jamaica to Great Britain, the first permanent settlement was established on Grand Cayman. Most of the settlers were British mariners and privateers and shipwrecked passengers and African slaves, as well as land-grant holders from Jamaica. The remoteness of the islands, and integration following the emancipation of slaves in 1835, resulted in a socially homogeneous society.

By the end of the 18th century, uncontrolled fishing eliminated the native turtle population, virtually the only resource of the island. Cayman Islanders searched farther and farther away for new turtle grounds, but, as international restrictions grew, turtle fishing was greatly reduced.

For some time the Cayman Islands were a dependency of Jamaica, becoming internally self-governing in July 1959. When Jamaica declared its independence (1962), the Caymans reverted to direct British rule. A new constitution providing for autonomy on most domestic issues was approved in 1972. The Caymans had by then developed offshore banking and tourism, enabling the colony to relinquish aid from Britain.   (C.A.Wi./E.P.E./Ed.)

For later developments in the history of the Cayman Islands, see the BRITANNICA BOOK OF THE YEAR.

Netherlands Antilles

The Netherlands Antilles (Dutch: Nederlandse Antillen) are composed of two widely separated groups of islands approximately 500 miles (800 kilometres) apart in the Caribbean Sea. Until 1986 Aruba was politically a part of the Netherlands Antilles, but in that year it obtained separate political status. The area of the islands is 309 square miles (800 square kilometres). The islands form an integral part of the Kingdom of The Netherlands and are fully autonomous in internal affairs. The southern group of islands, of which Aruba is geographically a part, includes Curaçao and Bonaire; they lie less than 50 miles off the Venezuelan coast. The northern group includes Sint Eustatius, Saba, and the southern part of Saint Martin (called Sint Maarten), the other part being administered by the French territory of Guadeloupe. Although the northern islands are referred to as "Windward" by locals, geographically this group lies within the Leeward Islands of the Lesser Antilles. The capital and largest city of the Netherlands Antilles is Willemstad on Curaçao.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* The southern islands are generally low in elevation, though hills range from the 787-foot (240-metre) Mount Brandaris in Bonaire to the 1,230-foot Mount Saint Christoffel in Curaçao. The islands consist mainly of igneous rocks and are fringed with coral reefs. The northern islands consist of volcanic rocks rising to Sentry Hill (1,119 feet) in the Dutch part of Saint Martin; Quill (1,198 feet), an extinct volcano on Sint Eustatius; and Mount Scenery, an extinct volcano on Saba that, at 2,910 feet (887 metres), is the islands' highest point. Curaçao, the largest island of the Netherlands Antilles (171 square miles), is indented in the south by deep bays, the largest of which, the Schottegat, provides a magnificent harbour for Willemstad. Bonaire, with an area of 111 square miles, lies about 20 miles east of Curaçao. Sint Eustatius (with an area of 8 square miles), along with Saba, forms the northwestern termination of the inner volcanic arc of the Lesser Antilles. Saba (5 square miles) consists of the peak of Mount Scenery surrounded by sea cliffs. The villages of The Bottom and Windwardside, occupying an old crater, are approached up a steep road from a rocky landing place on the south coast.

Drainage and soils. For the most part, the islands of the Netherlands Antilles have barren soil and little or no natural irrigation. On Curaçao and Bonaire there is much bare, eroded soil, the result of centuries of overgrazing. Drinking water on these islands is obtained mainly by distilling seawater.

Climate. Temperatures in the southern islands vary little from an annual average of 81° F (27° C), and the heat is tempered by the easterly trade winds. The islands

Geologic
formations

lie west of the usual hurricane zone. Rainfall in the south is low and variable, often less than 22 inches (550 millimetres) a year. The climate is similar in the northern islands, but rainfall is greater and hurricanes occur. The annual rainfall is greatest on Sint Eustatius and Saba (42 inches and 47 inches, respectively) and falls mainly between May and November, occasionally in association with hurricanes.

Plant and animal life. The vegetation of the southern Netherlands Antilles, much overgrazed by animals, is sparse. Cacti and other drought-resistant plants abound. The island of Bonaire is known for its flamingos.

Settlement patterns. More than 90 percent of the population is urban. The rural population of the islands is generally dispersed, and villages are scarce except on Saba. Characteristic of Curaçao are its *landhuizen,* large 18th- and 19th-century rural mansions located on hills. Willemstad has some splendid sections of Dutch-style colonial architecture with tropical adaptations, painted in white and pastel colours. More than 85 percent of the inhabitants of the islands reside on Curaçao; the next two most populous islands are Saint Martin and Bonaire. The most sparsely populated islands are Sint Eustatius and Saba.

Urban-
rural
distribution

The people. The islands have mostly black and mulatto populations except for Saba, which is about evenly divided between black and white. Most of the islands have small white minorities. Migration to Curaçao from other Caribbean islands, Venezuela, and Europe increased after the opening of its oil refinery in 1918.

Dutch is the official language, but Papiamento—a local Spanish-based creole that includes Portuguese, Dutch, and some African words—is widely used in the southern islands and is taught in elementary schools. English is the principal language of the northern islands, but Spanish also is spoken in the south. The major religion of the islands is Roman Catholicism, with small Methodist, Seventh-day Adventist, and Jewish minorities. For more than three centuries, a Sephardic Jewish community has lived in Curaçao.

The birth and death rates are relatively low, and the rate of natural increase is lower than on most other islands of the Caribbean. Migration to The Netherlands has increased.

The economy. Unlike most other Caribbean islands, the economy of the Netherlands Antilles never has been based on the export of sugar or other plantation crops, which the climatic conditions on the larger islands made impossible. Instead, Curaçao (and during the 18th century Sint Eustatius) developed into a regional trading and financial centre, activities that, together with oil refining and tourism, have become the basis of the islands' economy.

Resources. The southern islands have more exploitable minerals than the northern ones. Curaçao has some calcium phosphate mining; salt is processed on Bonaire.

Agriculture. Agriculture plays a minor role in the economy of the islands, although sugarcane and cotton plantations were once established on Saint Martin and Sint Eustatius. Curaçao was at one time used mainly for livestock raising, but, after the overgrazing of land, new small-scale agricultural ventures were begun, such as the cultivation of aloes for pharmaceutical products and oranges for Curaçao liqueur. Aloes also are grown on Bonaire. Fish are important to the economy of Sint Maarten. Saba is engaged chiefly in raising livestock and cultivating vegetables, particularly potatoes, which are exported to neighbouring islands.

Industry. The main industry of Curaçao is oil refining, which started with the opening up of the Venezuelan oil fields in 1914. After the oil refinery opened in 1918 on Curaçao, the industry became the economic mainstay of the islands. Bonaire has a textile factory, and Sint Maarten a rum distillery. Willemstad has become an important Caribbean banking centre. For all of the islands, tourism and service industries have become increasingly important.

Oil
refining

Trade. The main exports of the Netherlands Antilles are petroleum and petroleum products, all of which are produced on Curaçao. The entrepôt trade in the free ports of Curaçao is also significant. Curaçao's foreign trade is mainly with Venezuela, the United States, and The

Netherlands. Most of the islands' requirements of food and commercial goods are met by imports.

Transportation. Curaçao has an extensive road system and is linked to the outside world by Dutch, U.S., and Venezuelan airlines as well as by numerous steamship services. Sint Maarten also has an international airport.

Administration and social conditions. The Netherlands Antilles are a self-governing part of the Kingdom of The Netherlands. A governor, nominated by the local government and appointed by the crown, is the formal head of government and representative of the monarch. Executive authority is vested in a Council of Ministers headed by a prime minister. The council is responsible to the unicameral legislature (Staten), which is elected by universal adult suffrage. Although education in the Netherland Antilles is not compulsory, most of the population is literate. The main language of instruction is Dutch, and there is a university on Curaçao. The general standard of health on the islands is high.

Cultural life. Carnival time in February and the New Year's festivities are colourful celebrations. The Bonaire International Sailing Regatta is held every October, attracting boating enthusiasts from around the world. The 3,500-acre (1,420-hectare) national park on Curaçao showcases the island's wide variety of natural flora and fauna. Radio broadcasts are received throughout the islands, and there are television stations on Saint Martin and Curaçao.

HISTORY

The islands known as the Netherlands Antilles originally were inhabited by Arawak and Carib Indians; the arrival in the early 16th century of the Spanish caused the decimation of the native population. The Dutch, attracted by salt deposits, occupied the islands in the early part of the 17th century, and, except for brief periods of British occupation, the islands have remained Dutch possessions. Through much of the 17th and 18th centuries the islands prospered from Dutch trade in slaves, plantation products, and contraband, but the economy declined from 1816 until 1914.

Colonial rule. *Curaçao.* Curaçao was discovered by Alonso de Ojeda and Amerigo Vespucci in 1499 and settled in 1527 by the Spanish, who used it mainly for livestock raising. In 1634 Johannes van Walbeeck of the Dutch West India Company occupied and fortified the island, which became the base for a rich entrepôt trade flourishing through the 18th century. During the colonial period Curaçao was a major centre of Caribbean slave trade.

There were two short periods during the Napoleonic Wars when Curaçao was held by the British, but it was returned to The Netherlands by the Treaty of Paris in 1815. The 19th century was a period of economic decline partially alleviated by the cultivation of aloes and oranges. Only after the construction of the Schottegat oil refinery, however, did economic conditions greatly improve.

Bonaire. Bonaire also was discovered in 1499 by Ojeda and Vespucci. The island was settled by the Spanish in 1501 and claimed by the Dutch in 1634. It became part of the Dutch West India Company in 1636 and remained a government plantation until 1863. From 1807 to 1814 it was under British control.

Saint Martin. Discovered by Christopher Columbus on Nov. 11, 1493 (St. Martin's Day), the island was taken by French pirates in 1638, though the Spanish settled there in 1640. In 1648, French and Dutch prisoners of war allegedly met after the Spanish departure and amicably divided the island. The Dutch obtained the smaller but more valuable southern section, which contained large salt deposits.

Sint Eustatius. Sint Eustatius, first colonized by the French and English in 1625, was taken by the Dutch in 1632. It became the main centre of slave trade in the eastern Caribbean and by 1780 had a population of 2,500. In 1781 the British sacked Oranjestad (after the U.S. flag had officially been saluted there for the first time), and the island never regained its trade. In the 17th and 18th centuries most of the land was under sugarcane cultivation.

Saba. Saba was settled by the Dutch in 1632 but, be-

cause of its inaccessibility and ruggedness, never achieved any economic importance.

Political developments since World War II. After World War II, negotiations began with the aim of conferring a greater measure of self-government on the islands. On Dec. 15, 1954, a charter was signed making the islands an autonomous part of The Netherlands. In 1969, Curaçao was torn by labour conflicts leading to riots and arson. Since then discussions on complete independence have been held intermittently.

Politics in the Netherlands Antilles are now dominated by three issues: economic problems, the coming of independence, and the degree of autonomy to be afforded each island within the federation. By the mid-1970s it was clear that most of the Netherlands Antilles feared the economic consequences of independence. The Dutch government pressed for independence but insisted on preserving a federated structure embracing all islands. In an unofficial referendum in 1977, Aruba voted to secede from the Antilles federation but remained within the kingdom. By 1978 all the islands had accepted the concept of insular self-determination. (D.R.Ha./H.Ho.)

In 1989 the political leadership of Saint Martin announced its desire to achieve full independence in the shortest possible term; secessionist feelings were fueled by animosity toward the central administration in Curaçao. An investigation by the government of The Netherlands into the administration of Saint Martin resulted in 1993 in the arrest of two prominent leaders on charges of corruption and led to closer supervision by the metropolitan government of the island's affairs.

Efforts to placate secessionist sentiment in the islands by increasing insular autonomy apparently had the desired results, since during the mid-1990s all five islands voted to remain within the Netherlands Antilles. (H.Ho./Ed.)

For later developments in the history of the Netherlands Antilles, see the BRITANNICA BOOK OF THE YEAR.

Trinidad and Tobago

Trinidad and Tobago are two Caribbean islands that constitute an independent republic. Forming the two southernmost links in the Caribbean chain of islands, they lie close to the South American continent, northeast of Venezuela and northwest of Guyana. The country has a total area of 1,978 square miles (5,123 square kilometres). The capital of the republic, Port of Spain, is situated in the northwest of Trinidad.

Trinidad, the larger island, comprises 1,841 square miles. It is seven miles (11 kilometres) at the nearest point from the Venezuelan coast, from which it is separated by the Gulf of Paria and two narrow channels, where there are several small islands and rocks. Tobago, the smaller island, with an area of about 115 square miles, lies in the Atlantic, 19 miles to the northeast of Trinidad. Extending diagonally from southwest to northeast, Tobago is about 32 miles long and more than 11 miles across at its widest point. Little Tobago, also called Bird of Paradise Island, lies about a mile off Tobago's northeastern coast; it is noted as the only wild habitat (outside of New Guinea) of the greater bird-of-paradise.

Trinidad and Tobago achieved independence from the United Kingdom in 1962 and obtained membership in the Commonwealth in that year.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief and drainage.* Physiographically, the islands represent an extension of the South American mainland. The outstanding physical feature of Trinidad is its Northern Range (a continuation of the coastal ranges of the Andes Mountains in Venezuela), which runs from west to east at an average elevation of about 1,500 feet, rising to 3,084 feet (940 metres) at the Aripo Mountain, the country's highest peak. The Northern Range is the site of a large number of waterfalls, the most spectacular of which are the Blue Basin and the Maracas Falls, both 298 feet high. On the southern side of the range, foothills with an elevation of approximately 500 feet descend to the Northern Plain.

Marginal notes:

Independence movement

Centre of Caribbean slave trade

Little Tobago

Running across the centre of the island, from southwest to northeast, is the Central Range, the highest point of which is Mount Tamana (1,009 feet). A third row of mainly low hills, the Southern Range, adds further variety to the mostly flat or undulating surface of Trinidad.

These three mountain ranges determine the island's drainage pattern. Rivers are numerous but short, the longest being the Ortoire in the south (31 miles) and the Caroni in the north (25 miles). Swamps occupy parts of the low-lying areas, among them the Caroni Swamp in the northwest and clusters along the east and south coasts.

An oil-bearing belt occupies the southern quarter of the island, extending west into the Gulf of Paria and east into the Atlantic Ocean. Gas and water seepages give rise to mud volcanoes of various types, the best-known of which is called the Devil's Woodyard. In the southwest of the island is the sedimentary volcano known as the Pitch Lake, which contains reserves of asphalt.

Tobago is physiographically an extension of the Venezuelan coastal range and the Northern Range of Trinidad. Its dominant feature is the Main Ridge, which runs from northeast to southwest, rising to heights of about 1,800 feet. The ridge slopes more gently to the southwest onto a coral plain. The coral formation has given rise to a number of reefs, one of which, Buccoo Reef, is known for its marine life and is popular for scuba diving and snorkeling. The island has only a few short streams.

Climate. The climate of Trinidad and Tobago is tropical, with a high relative humidity. The coolest months are January and February, when the average minimum temperature is about 68° F (20° C). The warmest months are April, May, and October, which have an average maximum temperature of about 89° F (32° C). In general, mean temperatures range between 77° F (25° C) in February and 85° F (29° C) in April. Temperatures vary significantly between day and night, and the climate along the coast is tempered by sea breezes.

There is a main dry season from January to May and a lesser dry season (Petite Carême, or Indian Summer) in September and October. The prevailing winds are the northeast trades. The islands are outside the main hurricane zone, but Tobago occasionally is struck by a disastrous hurricane (*e.g.,* in 1867 and 1963).

Plant and animal life. Vegetation zones are well defined on both islands. In general, the highest areas coincide with the most luxuriant tropical rain forest vegetation. Cultivated estates or small settlements are established in clearings on the hills. In the dry season the hills are dotted with the orange flowers of the mountain immortelle, a large flowering tree that grows to a height of about 80 feet, and the gold flowers of the poui. Sugarcane, the main agricultural crop, is grown on Trinidad's Central Plain.

The Caroni Swamp, a bird sanctuary, is frequented by flocks of white flamingos and egrets as well as populations of scarlet ibis—a national bird. The greater bird-of-paradise has been introduced to the island of Little Tobago. The forests on both islands are hunting grounds for small game, the most sought after being the paca, or *lappe.* Other animals include the agouti (a short-haired, short-eared, rabbitlike rodent), collared peccary, or *quenck* (a wild hog), tattoo (an armadillo), prehensile-tailed porcupine, and iguana (a large lizard). There are four main groups of reptiles: snakes, lizards, turtles, and crocodiles (one kind, the caiman, related to the alligator).

Settlement patterns. Soils, climate, and vegetation all have influenced the pattern of local settlement. Villages stretch ribbonlike along the major roadways. In Trinidad, though not in Tobago, villages are so diverse in plan that it would be difficult to call any typical.

Even in the sugar belt of the Central Plain, with its mainly (though not exclusively) East Indian population, patterns vary. Kinship tends to be the important structural element in the life of the East Indian village in Trinidad; caste may also have a localized influence. Religious festivals, such as Dīwālī (Festival of Lights) and various forms of puja (ceremonial offering), are important events. Houses vary in size and architecture from the simple thatched hut to the well-built two-story dwelling, brightly painted and roofed with corrugated iron.

A somewhat different lifestyle prevails in villages inhabited by people predominantly of African descent, though many villages have both East Indian and African characteristics. Because of the conditioning of the slave system, traditional African culture has undergone considerable mutation or reinterpretation. The family unit is nuclear rather than extended and may be based upon marriage or upon a stable extralegal relationship.

These different rural cultural streams converge on the capital, Port of Spain. This city, with its mixed population, its Spanish influence (particularly in architecture), and French creole flavour, is one of the most cosmopolitan in the world. San Fernando, with its large East Indian population, is the second largest town and is located south of Port of Spain on the west coast. Arima is the oldest municipality in Trinidad. Scarborough, the chief town in Tobago, is an administrative centre and market town.

The people. The original inhabitants of Trinidad were chiefly Arawak. Although there are inhabitants of the town of Arima who claim descent from Carib royalty, it is doubtful that the land was settled by Caribs. Tobago was frequently visited by American Indians, probably both Arawak and Carib, but was not settled before the arrival of Columbus. Spanish, French, African, English, East Indian, and Chinese have all contributed to the ethnic composition of the islands' population. The various immigrant groups brought with them their languages, culture, and religion. Although English is the official language, four creole languages (Trinidad English, a French creole, a Spanish dialect creole, and Manzanillan—a melange of English, Spanish, and several African tongues) and some East Indian languages also are spoken.

Under the Spanish, Roman Catholicism was the official religion, and it was strengthened by French immigration during the French and Haitian revolutions. Protestantism gained a foothold in various forms (Anglican, Methodist, Moravian, and Baptist) with the advent of the British. East Indians brought with them their languages and their Hindu and Muslim religions. Both Sunnite and Shī'ite Muslim groups are present. Further diversification followed with the immigration of Syrians and Lebanese. African-influenced religious groups include the Shango and Shouter cults.

The first census of Trinidad and Tobago, in 1861, recorded a population of almost 100,000. By 1921 the population had more than tripled to some 360,000. Both the birth and death rates have remained fairly stable since the 1960s, and the rate of natural increase has been high. Emigration from the islands, however, has moderated the total population growth rate.

The economy. The petroleum industry continues to dominate the economy, which is thus subject to fluctuations in the global oil market. Tourism and manufacturing, however, have grown in importance. The unemployment rate is fairly high. Privatization of some state-owned enterprises was undertaken during the 1990s.

Resources. Oil production is both land- and sea-based. Trinidad has extensive oil and gas fields, as well as deposits of asphalt, coal, gypsum, limestone, sand and gravel, iron ore, argillite, and fluorspar. Natural gas has been found off the coasts of Trinidad and Tobago.

Agriculture. Agriculture is a relatively small sector of the economy. The major agricultural export commodities are sugar, cocoa, and coffee. Other agricultural products include coconuts, citrus fruits, rice, copra, poultry, and vegetables.

Industry. Oil production and refining is the major industry. Government policy has encouraged economic diversification to reduce dependence on imports and on petroleum production. Industrial plants are engaged in the assembly of consumer durables, including motor vehicles and radio and television receivers, and in the manufacture of fertilizers, cement, paper products, furniture, garments, and processed foods. Government enterprises include chemical and fertilizer plants and a steel mill.

Tourism is a rapidly growing industry in the country. It is based particularly on Tobago and on Trinidad's northwestern peninsula.

Transportation. The islands are served by a fairly well-

developed network of main and local roads, but there is heavy congestion in urban areas. Several small shipping lines and a domestic airline connect Tobago to Trinidad. Piarco International Airport on Trinidad and Crown Point Airport on Tobago have interisland connections and links with North and South America, western Europe, and the Caribbean. Port of Spain is the chief commercial port; petroleum exports are handled in southern ports. There are extensive port facilities at Point Lisas.

Administration and social conditions. *Government.* The first constitution, promulgated as a British Order in Council (1962), provided for a governor-general appointed by the British monarch, a cabinet, and a bicameral legislature. Under the constitution adopted in 1976, Trinidad and Tobago is a republic headed by an elected president.

The legislature consists of a 36-member House of Representatives, elected by universal adult suffrage every five years, and a 31-member Senate, whose members are appointed by the president on the advice of the prime minister and the minority party leader. The voting age is 18. Legislation passed in 1980 provided for a separate Tobago House of Assembly consisting of 12 members, elected at a primary election from electoral districts, who in turn elect three additional members as well as a chairman and deputy chairman. In January 1987 Tobago was granted full internal self-government. The legislation provides for a measure of devolution of executive powers in areas such as revenue raising and collection, agriculture, industry, tourism, environmental conservation, and social services. Trinidad is divided into 11 local government areas, including eight rural counties, which have county councils, and the three municipalities of Port of Spain, San Fernando, and Arima, which have municipal councils.

Education. Education is free at primary and secondary levels and compulsory between the ages of six and 12. However, there has been growing disparity between the number of school places and the growing number of school-age children, particularly at the secondary-school level. The University of the West Indies, offering courses in engineering, law, medicine, social science, natural science, education, agriculture, and the liberal arts, is located at St. Augustine, about eight miles east of Port of Spain. There are technical institutes in Port of Spain, Centeno, and San Fernando, as well as several teacher-training colleges.

Health and welfare. The demand for additional housing in the urban areas has increased, but construction has been hampered by population movement, high construction costs, shortage of land, and inadequate long-term financing. State provision for social security consists of noncontributory old-age pensions, noncontributory government employee pension schemes provided out of public revenues, and workers' compensation compulsorily paid by employers. A national health insurance scheme has been established. The proportion of doctors in the population has remained low, principally as a result of the emigration of doctors, but the general health of the population has improved.

Cultural life. Trinidad has many writers of international stature, including Samuel Selvon and V.S. Naipaul. The island is known for its steel band and calypso music and for the limbo. Derived from African music and dance forms, these are an important feature of the annual carnival celebration. Cricket is the most popular sport.

(A.N.R.R./Da.W.)

For statistical data on the land and people of Trinidad and Tobago, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

When Christopher Columbus reached Trinidad in 1498 on his third voyage, the island was inhabited by peoples who came originally from the Orinoco River delta region. Tribal groups speaking Arawakan languages were in the majority, but there were probably Carib speakers as well. In the 16th century many of these Trinidadian Indians were captured by Spanish slave traders and sent to work in other Spanish possessions, but there was no effective Spanish presence on the island until 1592. In that year, Antonio de Berrio took official possession of the island

and founded St. Joseph, the capital until 1784. Even after 1592 the development of the island proceeded slowly. Few Spaniards emigrated to Trinidad, only a handful of African slaves were imported, and there was little production or export. In the 17th and early 18th centuries, tobacco and, later, cacao were cultivated using Indian labour, but after a disastrous cacao failure in the 1720s the industry declined. The island remained undeveloped until the late 18th century.

From 1776 the Spanish government encouraged Roman Catholics from the other Caribbean islands to settle in Trinidad with their slaves. This immigration became significant after the Cedula (decree) of 1783, which offered generous land and tax incentives to settlers, and transformed Trinidad's population, economy, and society. Most of the settlers were French, and French influence became dominant. Many slaves were brought in from the other colonies and from Africa. Plantations were established, production of cotton and sugar began, and trade increased markedly. By 1797, when Britain seized the island from Spain, Trinidad had begun its development as a plantation economy and a slave society.

Trinidad was formally ceded to Britain in 1802. Under British rule, Trinidad's development as a sugar colony continued, although in 1806–07 the slave trade was completely prohibited. Slavery was abolished in two stages between 1834 and 1838, and the sugarcane planters were unable to secure the steady, tractable, and cheap labour they wanted. In 1845 the immigration of indentured workers from India began; it continued until 1917. As early as 1870, about a quarter of the total population consisted of Indians. The original Trinidadian Indian inhabitants had by then virtually disappeared. Other immigrants came to Trinidad after 1838 from the smaller British Caribbean colonies, Africa (as free settlers rescued from foreign slave ships), Madeira, China, Syria, Lebanon, Venezuela, and the United Kingdom. Trinidad's population became the most heterogeneous in the Caribbean.

Tobago, also sighted by Columbus in 1498, was virtually untouched by European settlement until the 18th century. Its development as a sugar colony began when it was ceded to Britain in 1763 and continued throughout the period from 1763 to 1814, when Tobago changed hands between Britain and France several times. Tobago's sugar production peaked in the 1790s but began an irreversible decline after 1807. Tobago was ceded to Britain for the last time in 1814, but by then its importance as a sugar-exporting colony had already begun to wane. Unlike Trinidad, Tobago had its own bicameral legislature until 1874. In 1889, with the island's economy in shambles as a result of the collapse of its sugar industry, Tobago was amalgamated with Trinidad, while retaining a subordinate legislature and separate taxes. In 1899 it became a ward (administrative district) of Trinidad and Tobago.

In 1925 a constitutional reform added seven elected members to Trinidad and Tobago's Legislative Council. Further agitation—especially an islandwide series of strikes and riots in 1937 under Uriah Butler—led to the grant of universal suffrage in 1945 and other constitutional reforms that provided for a measure of self-government. For about 10 years after universal suffrage, politics in the colony were characterized by individualism and confusion, but in 1956 the People's National Movement (PNM) won a victory at the polls and formed the first party-based cabinet government. Trinidad and Tobago attained independence in 1962 and became a republic within the Commonwealth in 1976.

The PNM won six consecutive elections and held power from 1956 to 1986. This continuity and stability in government were accompanied by economic problems and social unrest, culminating in widespread disturbances in 1970–71. But the oil boom in 1973–81 brought sudden prosperity to most sections of the population, and Trinidad and Tobago entered a period of rapid development and industrialization. A substantial state sector and fairly comprehensive social welfare programs were created from the petroleum profits, while the private sector expanded rapidly. The collapse of oil prices, along with the PNM's failure to win support from most Indo-Trinidadi-

Marginal notes: The 1976 constitution · African musical influence · British rule

ans and deep-seated corruption, led to a marked decline in the party's popularity.

In December 1986 the National Alliance for Reconstruction (NAR), a coalition party, won 33 of 36 seats on a program calling for divestment of most state-owned companies, reorganization of the civil service, and structural readjustment of the economy in the light of shrinking oil revenues. Although the NAR government succeeded somewhat in stimulating economic growth while keeping inflation low, its policies were widely resented and the party was damaged by splits and defections. In July 1990 a small, radical Muslim group attempted a coup in which several ministers, including the prime minister, were held hostage for six days. The NAR was defeated in elections in December 1991, and the PNM returned to power.

(B.M.B.)

Turks and Caicos Islands

The Turks and Caicos Islands, a British colony in the West Indies, consists of two groups of islands lying on the southeastern periphery of the Bahamas, of which they form a physical part, and north of the island of Hispaniola. The islands include eight large cays (keys) and numerous smaller cays, islets, reefs, banks, and rocks that have a combined area of 166 square miles (430 square kilometres). The Turks group is composed of Grand Turk, Salt Cay, and lesser cays. The Caicos group, which lies northwest of the Turks and is separated from them by a 22-mile (35-kilometre) deepwater channel, the Turks Island Passage, consists of six principal islands—South Caicos, East Caicos, Middle (or Grand) Caicos, North Caicos, Providenciales, and West Caicos—and several cays. Only six of the larger cays and two of the smaller cays are inhabited. More than 80 percent of the population lives on Grand Turk (which includes Cockburn Town—the seat of government and main commercial centre), South Caicos, and Providenciales. The name Turks allegedly derives from a species of cactus whose scarlet flowers resemble a Turkish fez; that of Caicos perhaps from *cay icoco* (a coco plum tree).

Name derivation

PHYSICAL AND HUMAN GEOGRAPHY

The land. The islands are low-lying coralline limestone precipitated from the ocean and have numerous karst features, including banana holes (small sinkholes containing rich soil), caves, caverns, and sea cliffs. Arable soil acreage is limited. Aragonite exists on the shallow banks off West Caicos. The highest elevation is 163 feet (50 metres), on Providenciales.

The climate is tropical savanna. Winter temperatures average between 75° and 80° F (24° and 27° C), summer temperatures between 85° and 90° F (29° and 32° C). The easterly trade winds moderate the climate. Rainfall averages about 29 inches (736 millimetres) annually at Grand Turk, and drinking water is in short supply. These are the driest islands in the Bahamas chain. The hurricane season is May through November. Hurricanes strike about every 10 years.

The types of vegetation encountered on the islands include xerophytic shrub-scrub, coppice, savanna, and marsh-swamp. Mangroves, cacti, and Caribbean pines are found, and beefwood trees (*Casuarina*) have been planted as a windbreak. Terrestrial animal life consists mostly of insects (especially butterflies and mosquitoes), lizards (notably iguanas), and birds (flamingos in particular); the islands are on migratory bird routes.

The people. More than 90 percent of the population are blacks. Native-born individuals are called "Belongers." About 14,000 Turks and Caicos citizens live in the Bahamas, where there is greater economic opportunity. The main religious denominations are Baptist, Methodist, and Anglican. English is the official language.

The economy. Lack of arable land restricts agriculture on the islands, though corn (maize), beans, cassava, and subsistence crops (staples and fruits) are grown on the western Caicos Islands. Rough grazing of beef cattle is the dominant land use, although much land is unused. Seafood is the major source of protein. Fishing—for lobster, conch, jacks, snapper, and others—and boatbuilding are traditional industries.

The islands have a food deficit, though lobster and conch are exported. Offshore financial services doing business with more than 7,000 registered companies also contribute to the economy.

Offshore banking

Three international airports and several smaller airstrips accommodate tourism, upon which the economy is heavily reliant. Grand Turk and Cockburn Harbour on South Caicos are main ports. Newer port facilities have opened on Providenciales, the main island for tourism.

Administration and social conditions. The constitution of 1976 provides for internal democratic self-government with an appointed executive council and an elected legislative assembly, over which a governor presides. Education is free and compulsory for children ages five to 15. Grand Turk has a hospital, and there are health clinics on several of the islands.

Cultural life. Water sports—sailing, big game fishing, and, especially, scuba diving among the coral reefs—are popular and attract tourists to the islands. Radio and satellite-cable television are available. Publications include the *Turks and Caicos News* (weekly) and *Conch News* (weekly).

For statistical data on the land and people of the Turks and Caicos Islands, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

A pre-Columbian Indian culture (Arawak perhaps) existed on the islands, but they were probably uninhabited when discovered by Juan Ponce de León, the Spanish explorer, in 1512. They remained mostly unsettled by Europeans until 1678, when Bermudans arrived and established a solar salt industry. The Caicos Islands were settled by royalist sympathizers from the United States after the War of Independence; they established cotton plantations employing slaves.

In 1799 the islands were annexed by the Bahama Islands government, but in 1848 they were granted a separate charter. In the meantime slavery had been abolished (1833–43), and the plantation owners left the islands, their former slaves remaining in possession.

Annexation by the Bahamas

After a period of financial difficulties, the colony was placed under the authority of the British governor-general at Kingston, Jam. (1874–1959), because ships voyaging between England and Jamaica passed the Turks and Caicos and made communication much easier than with Nassau in the Bahamas. The islands became a crown colony in 1962 when Jamaica became independent. For a time in the 1960s and '70s the islands were under the control of the Bahama Islands, but with Bahamian independence (1973) the Turks and Caicos were placed under a British governor at Grand Turk. As preparation for independence a commission was appointed in the 1980s to make recommendations on a new constitution and to consider the future economic direction of the islands. (J.H.Bo./Ed.)

For later developments in the history of the Turks and Caicos Islands, see the BRITANNICA BOOK OF THE YEAR.

BIBLIOGRAPHY

The region: General information on the West Indies and on the countries of the region is found in *South America, Central America, and the Caribbean* (biennial), a reference work from the Europa Publications series; *The South American Handbook*, ed. by JOHN BROOKS (annual); and *The Caribbean Handbook*, ed. by JEREMY TAYLOR (annual). DAVID WATTS, *The West Indies: Patterns of Development, Culture, and Environmental Change Since 1492* (1987), offers an authoritative historical geography that focuses on the human impact on the natural environment. Detailed geographic analysis is provided in ROBERT C. WEST and JOHN P. AUGELLI, *Middle America: Its Lands and Peoples*, 3rd ed. (1989). Guides to the West Indies include *Birnbaum's The Caribbean, Bermuda, and the Bahamas* (annual); and EUGENE H. KAPLAN, *A Field Guide to Southeastern and Caribbean Seashores* (1988), and *A Field Guide to Coral Reefs of the Caribbean and Florida* (1982), the last two focusing on the fauna of the region. JAMES BOND, *Birds of the West Indies*, 5th ed. (1985), is a well-illustrated reference work.

Studies of the human population of the region include SID-NEY W. MINTZ and SALLY PRICE (eds.), *Focus—Caribbean*, 11 issues (1984), a collection of essays on topics ranging from race and colour to language and emigration; DAVID LOWENTHAL, *West Indian Societies* (1972), focusing on social structure and social conditions; AARON LEE SEGAL (ed.), *Population Policies in the Caribbean* (1975); and H. HOETINK, *The Two Variants in Caribbean Race Relations: A Contribution to the Sociology of Segmented Societies* (1967; originally published in Dutch, 1962; reissued as *Caribbean Race Relations: A Study of Two Variants*, 1971). The society of the region is explored in M.G. SMITH, *The Plural Society in the British West Indies* (1965, reprinted 1974), and *Culture, Race, and Class in the Commonwealth Caribbean* (1984). See also FRANKLIN W. KNIGHT, *The Caribbean, the Genesis of a Fragmented Nationalism* (1978); FRANKLIN W. KNIGHT and COLIN PALMER (eds.), *The Modern Caribbean* (1989); Race, class, education, and population growth are considered in MALCOLM CROSS, *Urbanization and Urban Growth in the Caribbean: An Essay on Social Change in Dependent Societies* (1979). The roots of Caribbean culture are explored in MARGARET E. CRAHAN and FRANKLIN W. KNIGHT (eds.), *Africa and the Caribbean: The Legacies of a Link* (1979). PETER A. ROBERTS, *West Indians and Their Language* (1988), is an informed synthesis of research findings.

Economic analyses that address the history of the one-crop economy and the changes in attitude toward land since the emancipation of the slaves include JEAN BESSON and JANET MOMSEN (eds.), *Land and Development in the Caribbean* (1987); JOHN S. BRIERLEY and HYMIE RUBENSTEIN (eds.), *Small Farming and Peasant Resources in the Caribbean* (1988); and MALCOLM CROSS and ARNAUD MARKS (eds.), *Peasants, Plantations, and Rural Communities in the Caribbean* (1979). Works on the modern economies include ANTHONY PAYNE, *The Politics of the Caribbean Community, 1961–79: Regional Integration Among New States* (1980), on the efforts at economic integration; CARIBBEAN COMMON MARKET, *The Caribbean Community in the 1980s* (1981), a review report on economic progress; DELISLE WORRELL, *Small Island Economies: Structure and Performance in the English-Speaking Caribbean Since 1970* (1987), a study of postindependence developments; CLIVE Y. THOMAS, *The Poor and the Powerless: Economic Policy and Change in the Caribbean* (1988), focusing on the analysis of nationalist economic models; and CAREY R. D'AVINO, *Caribbean Tax Havens* (1986), a specially commissioned report on the tax advantages for foreign investments, a specialty of the Caribbean economy.

Many histories of the region explore slavery and its origins and consequences: CARL BRIDENBAUGH and ROBERTA BRIDENBAUGH, *No Peace Beyond the Line: The English in the Caribbean, 1624–1690* (1972); RICHARD S. DUNN, *Sugar and Slaves: The Rise of the Planter Class in the English West Indies, 1624–1713* (1972); RICHARD B. SHERIDAN, *Sugar and Slavery: An Economic History of the British West Indies, 1623–1775* (1974); B.W. HIGMAN, *Slave Populations of the British Caribbean, 1807–1834* (1984); MICHAEL CRATON, *Testing the Chains: Resistance to Slavery in the British West Indies* (1982); WILLIAM A. GREEN, *British Slave Emancipation: The Sugar Colonies and the Great Experiment, 1830–1865* (1976); MANUEL MORENO FRAGINALS, FRANK MOYA PONS, and STANLEY L. ENGERMAN (eds.), *Between Slavery and Free Labor: The Spanish-Speaking Caribbean in the Nineteenth Century* (1985); R.W. BEACHEY, *The British West Indies Sugar Industry in the Late 19th Century* (1957, reprinted 1978); and MALCOLM CROSS and GAD HEUMAN (eds.), *Labour in the Caribbean: From Emancipation to Independence* (1988). The rise of the post-emancipation peasantry is explored in SIDNEY W. MINTZ, *Caribbean Transformations* (1974, reissued 1984); GORDON K. LEWIS, *The Growth of the Modern West Indies* (1968), is a general history. A path-breaking work relating to dependency is ERIC WILLIAMS, *Capitalism & Slavery* (1944, reissued 1983); economic dependency on foreign countries is developed in ANTHONY PAYNE and PAUL SUTTON (eds.), *Dependency Under Challenge: The Political Economy of the Commonwealth Caribbean* (1984). The history of political and ideological conflict in the contemporary West Indies is told in ANTHONY PAYNE, *The International Crisis in the Caribbean* (1984); PAUL SUTTON, *Dual Legacies in the Contemporary Caribbean: Continuing Aspects of British and French Dominion* (1986); ROBERT D. CRASSWELLER, *The Caribbean Community: Changing Societies and U.S. Policy* (1972); and VIRGINIA R. DOMÍNGUEZ and JORGE I. DOMÍNGUEZ, *The Caribbean, Its Implications for the United States* (1981).

Greater Antilles: (Cuba): Basic information is presented in *Cuba, a Country Study*, 3rd ed., edited by JAMES D. RUDOLPH (1985), which includes an extensive bibliography. ANTONIO NÚÑEZ JIMÉNEZ, *Geografía de Cuba*, 3 vol. (1972), provides a survey. SERGIO G. ROCA (ed.), *Socialist Cuba: Past Interpretations and Future Challenges* (1988), explores, among other topics, demography, religion, and race relations. Problems of population migration and employment are studied in

JOSÉ LUIS LUZÓN, *Economía, población y territorio en Cuba, 1899–1983* (1987). Historical aspects of economic development are explored in LEVÍ MARRERO, *Cuba, economía y sociedad* (1972–), with 14 volumes published by 1989. Studies on contemporary economic conditions include CARMELO MESA-LAGO, *The Economy of Socialist Cuba: A Two-Decade Appraisal* (1981); CLAES BRUNDENIUS, *Revolutionary Cuba, the Challenge of Economic Growth with Equity* (1984); JORGE F. PÉREZ-LÓPEZ, *Measuring Cuban Economic Performance* (1987); and ANDREW ZIMBALIST (ed.), *Cuba's Socialist Economy Toward the 1990s* (1987). Cultural developments and policies are surveyed in AR-MANDO HART DÁVALOS and LUIS BÁEZ, *Changing the Rules of the Game* (1983; originally published in Spanish, 1983). ALEJO CARPENTIER, *Ese músico que llevo dentro 3: la música en Cuba* (1987), explores Cuban music; and MICHAEL CHANAN, *The Cuban Image: Cinema and Cultural Politics in Cuba* (1985), discusses the political aspects of filmmaking in the country.

JAIME SUCHLICKI, *Historical Dictionary of Cuba* (1988), provides comprehensive information on persons, places, and events from 1492 to 1985 and includes a bibliography. HUGH THOMAS, *Cuba: The Pursuit of Freedom* (1971), is a massive history. Detailed examinations of the historical role of sugar growing and slavery include MANUEL MORENO FRAGINALS, *The Sugarmill: The Socioeconomic Complex of Sugar in Cuba, 1760–1860* (1976; originally published in Spanish, 1964); FRANKLIN W. KNIGHT, *Slave Society in Cuba During the Nineteenth Century* (1970); and REBECCA J. SCOTT, *Slave Emancipation in Cuba: The Transition to Free Labor, 1860–1899* (1985). Excellent treatments embracing the achievements of modern historiography include LOUIS A. PÉREZ, JR., *Cuba Between Empires, 1878–1902* (1983), *Cuba Under the Platt Amendment, 1902–1934* (1986), and *Cuba: Between Reform and Revolution* (1988). Studies of the 20th century, with special emphasis on Castro and the revolution, include CARMELO MESA-LAGO (ed.), *Revolutionary Change in Cuba* (1971); JORGE I. DOMÍNGUEZ, *Cuba: Order and Revolution* (1978); CARMELO MESA-LAGO, *Cuba in the 1970s: Pragmatism and Institutionalization*, rev. ed. (1978); TAD SZULC, *Fidel: A Critical Portrait* (1986); and MAX AZICRI, *Cuba: Politics, Economics, and Society* (1988). The role of revolutionary Cuba in the world is assessed in WAYNE S. SMITH, *The Closest of Enemies: A Personal and Diplomatic Account of U.S.-Cuban Relations Since 1957* (1987); BARRY B. LEVINE (ed.), *The New Cuban Presence in the Caribbean* (1983); COLE BLASIER and CARMELO MESA-LAGO (ed.), *Cuba in the World* (1979); and JORGE I. DOMÍNGUEZ (ed.), *Cuba: Internal and International Affairs* (1982).

(Dominican Republic): Comprehensive treatment is found in THOMAS E. WEIL *et al.*, *Area Handbook for the Dominican Republic*. 2nd ed. (1973, reissued as *Dominican Republic, a Country Study*, 1982). Other general surveys include IAN BELL, *The Dominican Republic* (1981); and HOWARD J. WIARDA and MICHAEL J. KRYZANEK, *The Dominican Republic, a Caribbean Crucible* (1982), a discussion of the land, people, economy, and politics in a contemporary and historical setting. A more detailed study of the population and its social and economic situation is found in H. HOETINK, *The Dominican People, 1850–1900: Notes for a Historical Sociology* (1982; originally published in Spanish, 1971). Later social and economic developments are studied in KENNETH EVAN SHARPE, *Peasant Politics: Struggle in a Dominican Village* (1977), which discusses local-level politics and the international economic system; and JOSÉ A. MORENO, *Barrios in Arms: Revolution in Santo Domingo* (1970), a sociologist's eyewitness account of the impact of the 1965 revolution on inner-city Santo Domingo. An analysis of the impact of population migration is presented in GLENN L. HENDRICKS, *The Dominican Diaspora: From the Dominican Republic to New York City—Villagers in Transition* (1974).

ROBERT D. CRASSWELLER, *Trujillo: The Life and Times of a Caribbean Dictator* (1966), though a biography, serves as a good introduction to 20th-century history. JOHN BARTLOW MARTIN, *Overtaken by Events: The Dominican Crisis from the Fall of Trujillo to the Civil War* (1966), is the story of the 1965 revolution written by the former U.S. ambassador; while ABRAHAM E. LOWENTHAL, *The Dominican Intervention* (1972), is a historian's analysis of the same events. Interpretive studies of postrevolutionary history include HOWARD J. WIARDA, *Dictatorship, Development, and Disintegration: Politics and Social Change in the Dominican Republic*, 3 vol. (1975); and MICHAEL J. KRYZANEK and HOWARD J. WIARDA, *The Politics of External Influence in the Dominican Republic* (1988).

(Haiti): THOMAS E. WEIL *et al.*, *Area Handbook for Haiti* (1973, reissued as *Haiti, a Country Study*, 1986), provides a geographic summary. GUY LASSERRE, PAUL MORAL, and PIERRE USSELMANN (eds.), *Atlas d'Haiti* (1985), is a collection of maps prepared by an international team of specialists. An important source on the geography of the colony of Saint-Domingue is MÉDÉRIC-LOUIS-ELIE MOREAU DE SAINT-MÉRY, *A Civilization That Perished: The Last Years of White Colonial Rule in Haiti,*

ed. by IVOR D. SPENCER (1985; originally published in French, 2 vol., 1797–98). For views of Haitian society, see JAMES G. LEYBURN, *The Haitian People*, rev. ed. (1966, reprinted 1980); PAUL MORAL, *Le Paysan haïtien: étude sur la vie rurale en Haïti* (1961, reprinted 1978); MATS LUNDAHL, *Peasants and Poverty: A Study of Haiti* (1979); ANDRÉ-MARCEL D'ANS, *Haïti, paysage et société* (1987); CHARLES R. FOSTER and ALBERT VALDMAN, *Haiti Today and Tomorrow: An Interdisciplinary Study* (1984); and DAVID NICHOLLS, *From Dessalines to Duvalier: Race, Colour, and National Independence in Haiti* (1979, reissued 1988). Economic conditions in Haiti are analyzed in MATS LUNDAHL, *The Haitian Economy: Man, Land, and Markets* (1983); SIMON M. FASS, *Political Economy in Haiti: The Drama of Survival* (1988); and CHRISTIAN A. GIRAULT, *Le Commerce du café en Haïti: habitants, spéculateurs et exportateurs* (1981), a discussion of the coffee trade. For culture, see HAROLD COURLANDER, *The Drum and the Hoe: Life and Lore of the Haitian People* (1960, reprinted 1985); and J. MICHAEL DASH, *Literature and Ideology in Haiti, 1915–1961* (1981).

RAYFORD W. LOGAN, *Haiti and the Dominican Republic* (1968), is a standard history; BRIAN WEINSTEIN and AARON SEGAL, *Haiti: Political Failures, Cultural Successes* (1984), covers the developments of the 1970s; and ALEX DUPUY, *Haiti in the World Economy: Class, Race, and Underdevelopment Since 1700* (1989), is a perceptive political history with an economic focus.

(*Jamaica*): A general work is IRVING KAPLAN et al., *Area Handbook for Jamaica* (1976). For physical geography, see R.M. BENT and ENID L. BENT-GOLDING, *A Complete Geography of Jamaica* (1966), an illustrated survey; and BARRY FLOYD, *Jamaica: An Island Microcosm* (1979). Reference information is found in COLIN G. CLARKE, *Jamaica in Maps: Graphic Perspectives of a Developing Country* (1974). A discussion of Jamaican geology is included in ALAN G. FINCHAM, *Jamaica Underground: A Register of Data Regarding the Caves, Sinkholes, and Underground Rivers of the Island* (1977). A brief review of both physical and social geography is MIKE MORRISSEY, *Our Island, Jamaica* (1983). See also L. ALAN EYRE, *Geographic Aspects of Population Dynamics in Jamaica* (1972). MERVYN C. ALLEYNE, *Roots of Jamaican Culture* (1988), focuses on African influences in Jamaican culture.

CLINTON V. BLACK, *The History of Jamaica*, new ed. (1983), offers a general outline. The material on the Jamaican Arawak is scarce, but much of the literature is summarized in the opening chapters of FRANCIS J. OSBORNE, *History of the Catholic Church in Jamaica* (1977, reissued 1988). On the Spanish period, FRANCISCO MORALES PADRÓN, *Jamaica española* (1952), remains the most substantial work. S.A.G. TAYLOR, *The Western Design: An Account of Cromwell's Expedition to the Caribbean* (1965), discusses the English invasion and early settlement. The plantation as an institution is explored in MICHAEL CRATON, *Searching for the Invisible Man: Slaves and Plantation Life in Jamaica* (1978). MAVIS C. CAMPBELL, *The Maroons of Jamaica, 1655–1796: A History of Resistance, Collaboration & Betrayal* (1988), focuses on activities and communities in the 18th century. For later periods, see EDWARD BRATHWAITE, *The Development of Creole Society in Jamaica, 1770–1820* (1971); B.W. HIGMAN, *Slave Population and Economy in Jamaica, 1807–1834* (1976); DOUGLAS HALL, *Free Jamaica, 1838–1865: An Economic History* (1959); PHILIP CURTIN, *Two Jamaicas* (1955, reissued 1970); MAVIS C. CAMPBELL, *The Dynamics of Change in Slave Society* (1976); and GAD HEUMAN, *Between Black and White: Race, Politics, and the Free Coloreds in Jamaica, 1792–1865* (1981), the last two focusing on the transition from slavery to emancipation. SYDNEY H. OLIVIER (LORD OLIVIER), *Jamaica, the Blessed Island* (1936, reissued 1971), provides a view of the penultimate stage of British colonial rule. Sociopolitical and economic changes of the 20th century are analyzed in EVELYNE HUBER STEPHENS and JOHN D. STEPHENS, *Democratic Socialism in Jamaica: The Political Movement and Social Transformation in Dependent Capitalism* (1986); and ANTHONY PAYNE, *Politics in Jamaica* (1988).

(*Puerto Rico*): RAFAEL PICÓ, *The Geography of Puerto Rico* (1974), offers a comprehensive survey. Anthropological, ethnological, demographic, and cultural features are discussed in JOSEPH P. FITZPATRICK, "Puerto Ricans," pp. 858–867 in STEPHAN THERNSTROM (ed.), *Harvard Encyclopedia of American Ethnic Groups* (1980); JULIAN H. STEWARD et al., *The People of Puerto Rico: A Study in Social Anthropology* (1956); MARÍA TERESA BABÍN, *The Puerto Ricans' Spirit: Their History, Life, and Culture* (1971; originally published in Spanish, 1970); and STAN STEINER, *The Islands: The Worlds of the Puerto Ricans* (1974). For the country's economy, see ROBERT J. TATA and DAVID R. LEE, "Puerto Rico: Dilemmas of Growth," *Focus* 28(2):1–10 (November–December 1977); UNITED STATES. DEPARTMENT OF COMMERCE, *Economic Study of Puerto Rico*, 2 vol. (1979); and JAMES L. DIETZ, *Economic History of Puerto Rico: Institutional Change and Capitalist Development* (1986).

Comprehensive histories are provided by KAL WAGENHEIM, *Puerto Rico: A Profile*, 2nd ed. (1975); and KAL WAGENHEIM and OLGA JIMENEZ DE WAGENHEIM (eds.), *The Puerto Ricans: A Documentary History* (1973). Other historical studies include ARTURO MORALES CARRIÓN, *Puerto Rico and the Non-Hispanic Caribbean: A Study in the Decline of Spanish Exclusivism*, 2nd ed. (1971), with an analysis of the development of trade and commerce, and *Puerto Rico, a Political and Cultural History* (1983); HENRY WELLS, *The Modernization of Puerto Rico: A Political Study of Changing Values and Institutions* (1969); THOMAS G. MATHEWS, *Puerto Rican Politics and the New Deal* (1960, reprinted 1976); and, on the contemporary situation, RAYMOND CARR, *Puerto Rico, a Colonial Experiment* (1984).

Lesser Antilles: There are few works that treat all the islands of the Lesser Antilles or describe a particular island comprehensively, although a number of broad overviews are listed in the earlier section on the region. An informative geologic survey, covering locations from both the Lesser Antilles and the Netherlands Antilles, is offered in J.H. WESTERMANN and H. KIEL, *The Geology of Saba and St. Eustatius, with Notes on the Geology of St. Kitts, Nevis, and Montserrat, Lesser Antilles* (1961). GUY LASSERRE, *La Guadeloupe: Étude géographique*, 3 vol. (1978), is a detailed geography. Studies of flora include CLARISSA THÉRÈSE KIMBER, *Martinique Revisited: The Changing Plant Geographies of a West Indian Island* (1988); and DAVID WATTS, *Man's Influence on the Vegetation of Barbados, 1627 to 1800* (1966).

The people of Barbados are discussed in JILL SHEPPARD, *The "Redlegs" of Barbados, Their Origins and History* (1977), which explores the history of indentured servants; FARLEY BRATHWAITE (ed.), *The Elderly in Barbados* (1986), a survey of social and economic conditions of the elderly; and GRAHAM M.S. DANN (ed.), *Everyday in Barbados: A Sociological Perspective* (1976), which discusses social structures and recreational activity. JEAN BENOIST (ed.), *L'Archipel inachevé: culture et société aux Antilles françaises* (1972), is an anthropological study of the French islands of Martinique, Guadeloupe, La Désirade, Marie-Galante, and Saint-Barthélemy. STUART B. PHILPOTT, *West Indian Migration: The Montserrat Case* (1973), explores the impact of migration on village population. BONHAM C. RICHARDSON, *Caribbean Migrants: Environment and Human Survival on St. Kitts and Nevis* (1983), focuses on migration as a response to degradation of environment. KAREN FOG OLWIG, *Cultural Adaptation and Resistance on St. John: Three Centuries of Afro-Caribbean Life* (1985), examines the society of one of the Virgin Islands.

Analyses of economic conditions include DELISLE WORRELL (ed.), *The Economy of Barbados, 1946–1980* (1982), a study of the trends of the major sectors; BONHAM C. RICHARDSON, *Panama Money in Barbados, 1900–1920* (1985), which discusses the impact of remittances on a wide range of economic activities and social attitudes; MICHEL-ROLPH TROUILLOT, *Peasants and Capital: Dominica in the World Economy* (1988), which explores patterns of land ownership and agricultural production; and C. BOURNE, E.R. LEFRANC, and F. NUNES (compilers), *Small Farming in the Less Developed Countries of the Commonwealth Caribbean* (1980), which provides information on Grenada, Saint Vincent and the Grenadines, Saint Lucia, Dominica, Saint Kitts and Nevis, Montserrat, and Antigua. Studies of individual island-state economies include JOHN S. BRIERLEY, *Small Farming in Grenada, West Indies* (1974); DEIRDRE M. KELLY, *Hard Work, Hard Choices: A Survey of Women in St. Lucia's Export-Oriented Electronics Factories* (1987); and HYMIE RUBENSTEIN, *Coping With Poverty: Adaptive Strategies in a Caribbean Village* (1987).

Historical works which concentrate mostly on slavery and plantation life include the following: VINCENT T. HARLOW, *A History of Barbados, 1625–1685* (1926, reprinted 1969), an examination of the period of the early British colonies; GARY A. PUCKREIN, *Little England: Plantation Society and Anglo-Barbadian Politics, 1627–1700* (1984), a revisionist economic history, particularly strong on the creolizing process; HILARY BECKLES, *Black Rebellion in Barbados: The Struggle Against Slavery, 1627–1838* (1984), a provocative interpretation of slave resistance. JEROME S. HANDLER, *The Unappropriated People: Freedmen in the Slave Society of Barbados* (1974), which fills a gap in historiography; KARL WATSON, *The Civilised Island, Barbados: A Social History, 1750–1816* (1979), a study of the mature slave society; CLAUDE LEVY, *Emancipation, Sugar, and Federalism: Barbados and the West Indies, 1833–1876* (1980), on postslavery adjustments; GORDON C. MERRILL, *The Historical Geography of St. Kitts and Nevis, the West Indies* (1958), which discusses the colonial period on the islands; LENNOX HONYCHURCH, *The Dominica Story: A History of the Island*, 2nd ed. (1984), a well-illustrated study covering developments up to the 1980s and benefiting from the author's personal involvement in the constitutional changes leading to independence; and GEORGE BRIZAN, *Grenada, Island of Conflict: From*

Amerindians to People's Revolution, 1498–1979 (1984), the work of a Grenadian historian and politician.

Other islands: (Aruba and Netherlands Antilles): Although independent, Aruba is often treated in the literature with the Netherlands Antilles. Geographic information is given in J.H. WESTERMANN and J.I.S. ZONNEVELD, *Photo-Geological Observations and Land Capability & Land Use Survey of the Island of Bonaire, Netherlands Antilles* (1956); RENÉ RÖMER, *Curaçao* (1981; originally published in Dutch, 1977); JOHN Y. KEUR and DOROTHY L. KEUR, *Windward Children: A Study in Human Ecology of the Three Dutch Windward Islands in the Caribbean* (1960); H. HOETINK, *Het patroon van de oude Curaçaose samenleving* (1958), a sociological study, including a discussion of race; FOLKERT STEENMEIJER, *Food and Nutrition of Arubans* (1957); VERA M. GREEN, *Migrants in Aruba: Interethnic Integration* (1974); JULIA G. CRANE, *Educated to Emigrate: The Social Organization of Saba* (1971); and ANKE KLOMP, *Politics on Bonaire* (1987; originally published in Dutch, 1983).

A comprehensive history of the Netherlands Antilles, including Aruba, is JOHANNES HARTOG, *Geschiedenis van de Nederlandse Antillen*, 5 vol. (1954–81). One-volume treatments are CORNELIS C. GOSLINGA, *The Dutch in the Caribbean and on the Wild Coast, 1580–1680* (1971), *The Dutch in the Caribbean and in the Guianas, 1680–1791* (1985), and *A Short History of the Netherlands Antilles and Surinam* (1979), a concise survey. An overview of historical sources is given in M.A.P. MEILINK-ROELOFSZ (ed.), *Dutch Authors on West Indian History: A Historiographical Selection*, trans. from Dutch (1982). A special history is ISAAC S. EMMANUEL and SUZANNE A. EMMANUEL, *History of the Jews of the Netherlands Antilles*, 2 vol. (1970).

(The Bahamas): Geographic information is available in GAIL SAUNDERS, *The Bahamas: A Family of Islands* (1988), a general guidebook; MARY MOSELEY, *The Bahamas Handbook* (1926), a classic study of landscape, flora, fauna, history, economy, and tourism that covers the islands from Grand Bahama to Grand Turk; MICHAEL CRATON, *Sun 'n Sixpence: A Guide to Nassau and the Bahama Out Islands* (1964), a descriptive handbook; and MICHAEL HALKITIS, KAREN RIGG, and STEVEN SMITH, *The Climate of the Bahamas* (1980), including an examination of Grand Turk. NATHANIEL LORD BRITTON and CHARLES FREDERICK MILLSPAUGH, *The Bahama Flora* (1962), provides an examination of the botanical species on the islands from Grand Bahama to Grand Turk. Historic architecture is discussed in GAIL SAUNDERS and DONALD CARTWRIGHT, *Historic Nassau* (1979). Works on the Family Islands include STEVE DODGE, *Abaco: The History of an Out Island and Its Cays* (1983); and MARGERY O. ERICKSON, *Great Inagua* (1987).

The most comprehensive general history is MICHAEL CRATON, *A History of the Bahamas*, 3rd ed. (1986). PAUL ALBURY, *The Story of the Bahamas* (1975), expands on the growth of tourism, political parties, and nationalism and gives special attention to the Family Islands, and is his *Paradise Island Story* (1984) is also useful. The loyalists and the slavery period are examined in GAIL SAUNDERS, *Bahamian Loyalists and Their Slaves* (1983), and *Slavery in the Bahamas, 1648–1838* (1985). Political histories include RANDOL FAWKES, *The Faith that Moved the Mountain* (1979); DORIS L. JOHNSON, *The Quiet Revolution in the Bahamas* (1972); and COLIN A. HUGHES, *Race and Politics in the Bahamas* (1981).

(Cayman Islands): Pictorial works include PAUL HUMANN, *Beautiful Isles, Cayman* (1986); and PAUL HUMANN and FEODOR PITCAIRN, *Cayman, Underwater Paradise* (1979). Information on the people is available from government publications such as *Statistical Abstracts of the Cayman Islands* (annual); CAYMAN ISLANDS, *Annual Reports;* and Cayman Islands Government, *Economic & Financial Review* (1982).

The most useful source on history remains GEORGE S.S. HIRST, *Notes on the History of the Cayman Islands,* in parts (1909–10, reprinted 5 vol. in 3, 1967). NEVILLE WILLIAMS, *A History of the Cayman Islands* (1970), is a short survey. ULF HANNERZ, *Caymanian Politics: Structure and Style in a Changing Island Society* (1974), is also of interest.

(Trinidad and Tobago): Geography is discussed in HELMUT BLUME, *The Caribbean Islands* (1974; originally published in German, 1968); and JEREMY TAYLOR, *Masquerade: The Visitor's Introduction to Trinidad and Tobago* (1986).

History is explored in ERIC E. WILLIAMS, *History of the People of Trinidad and Tobago* (1962); ARIE BOOMERT, "The Arawak Indians of Trinidad and Coastal Guiana, ca. 1500–1650," *Journal of Caribbean History,* 19(2):123–188 (1984); LINDA A. NEWSON, *Aboriginal and Spanish Colonial Trinidad: A Study in Culture Contact* (1976); BRIDGET BRERETON, *Race Relations in Colonial Trinidad, 1870–1900* (1979), which explores the multiethnic population characteristics of Trinidad, and *A History of Modern Trinidad, 1783–1962* (1981); and DONALD WOOD, *Trinidad in Transition* (1968, reissued 1986).

(Turks and Caicos): Information on these islands is found in works cited above in the section on the Bahamas. Works specifically on the Turks and Caicos include *Turks and Caicos Islands* (annual), a standard reference paper of the Foreign and Commonwealth Office of the British Government that provides basic facts; DONOVAN S. CORRELL and HELEN B. CORRELL, *Flora of the Bahama Archipelago: Including the Turks and Caicos Islands* (1982); W. JOHN RODMAN, "Turks and Caicos Islands: The Caribbean Secret," *The Caribbean & West Indian Chronicle,* special issue (June–July 1983), on economic conditions; J. HARRISON *et al.,* "Tourism and Development: The Problems of Small Islands in the Caribbean," *Environments,* 16(3):125–130 (1984), a study of Turks and Caicos economic development; C.O. HESSE and K. HESSE, "Conch History in the Turks and Caicos Islands," *Underwater Naturalist,* 10(3):4–9 (1977), which discusses ecology and commercial fishing; and JAMES H. STARK, *Stark's History and Guide to the Bahama Islands: Including Their History, Inhabitants, Climate, Agriculture, Geology, Government, and Resources* (1891), a classic background study that provides a history.

Western Africa

South of the Sahara and east and north of the Atlantic Ocean, western Africa is latitudinally divided into two parallel belts of land: the western portion of the Sudan, a geographic area that stretches across the entire width of Africa, and the coastal region, or Guinea Coast. Each belt has its own geography, cultures, and history.

The nations of the western Sudan include Burkina Faso (formerly Upper Volta), Cape Verde, Chad, The Gambia, Mali, Mauritania, Niger, and Senegal. The nations of the Guinea Coast are Benin, Cameroon, Côte d'Ivoire (Ivory Coast), Equatorial Guinea, Ghana, Guinea, Guinea-Bissau, Liberia, Nigeria, Sierra Leone, and Togo.

Western Africa is a term used in the *Encyclopædia Britannica* to designate a geographic region within the continent of Africa. The term West Africa is also often used to refer to this part of the continent. As conventionally understood, however, West Africa comprises all of the areas considered here except Cameroon, Chad, Equatorial Guinea, and the Saharan parts of Mali, Mauritania, and Niger. West Africa is primarily a political and economic designation; these countries joined to establish the Economic Community of West African States (ECOWAS) in 1975.

The article is divided into the following sections:

THE REGION

Physical and human geography

THE LAND

Geology. Western Africa is underlain by crystalline rocks that outcrop over about 55 percent of the subcontinent, elsewhere being buried under sedimentary rocks. Volcanic rocks constitute a third, small group of surface rocks.

The crystalline rocks, collectively referred to as the West African shield or craton, comprise three main types of rock assemblage. The basement complexes are highly deformed and contorted gneisses, migmatites (metamorphosed and banded mixed rocks), quartzites, and amphibolites. The supracrustal formations of phyllites, schists, banded ironstones, quartzites, and greenstones were originally laid down upon preexisting basement complexes as sedimentary and volcanic formations, but they have been folded, faulted, and metamorphosed during one or more episodes of orogenic deformation. The granitic intrusions, varying from several to hundreds of square miles in area, were intruded into basement complexes and supracrustals at the end of major tectonic events.

The West African shield consists of three age provinces. The oldest part, whose assemblages are Archean with reactivation ages older than 2.5 billion years, lies in Sierra Leone, Liberia, and Guinea and is called the Liberian Craton. The central part—in Côte d'Ivoire, Ghana, and Burkina Faso—is dominated by the Birimian supracrustals, which were deposited during the Proterozoic era and tectonized in the Eburnian event of 1.8 to two billion years ago. In the east, beneath Benin, Togo, Nigeria, Chad, and Niger, the shield contains Archean-age basement complexes and Proterozoic supracrustals, which were deformed and the basement reactivated between 650 and 500 million years ago during the Pan-African thermotectonic

event (see below). In the far west, the Rokelide and Mauritanide metamorphosed and deformed rocks of Guinea and Sierra Leone show ages of 550 to 350 million years. As elsewhere in Africa, the shield rocks contain abundant and diverse mineral resources including iron ore, gold, rutile, bauxite, chromite, manganese, diamonds, copper, lead, zinc, and uranium, though many occurrences are small and low-grade.

The sedimentary rocks lie on the shield in broad, shallow (a maximum of three miles [five kilometres] thick) basins to the north and in narrow, deeper (a maximum of 7.5 miles thick) basins along the coast. The rock types include shales, sandstones, conglomerates, and limestones, which were originally deposited in vast lakes, deltas, and shallow seas. There were three long periods of sedimentation, although each period contained phases of erosion.

The oldest formations span the later Proterozoic to Paleozoic eras, from about one billion to about 350 million years ago, and include sediments of two glaciations, for during parts of this time the western African region lay close to the South Pole. These older formations were laid down in the Volta and Taoudeni basins (the latter one of the largest sedimentary basins in the world), and parts were involved later in the Pan-African orogenesis. The sandstones and conglomerates are now very hard and resistant and form prominent escarpments, such as the Volta and the Bandiagara, and plateaus, such as the Fouta Djallon and the Manding.

The second major period of sedimentation was during the Mesozoic and the early Cenozoic eras, from 200 to 65 million years ago, when the vast inland basins of Iullmedan and Chad and the narrower Benue basin developed. During this period the Atlantic Ocean began to open, and the sedimentary coastal basins of Senegal, Sierra Leone, Côte d'Ivoire, and southern Nigeria formed along

The West African shield

the continental margins. Sedimentation has continued to the present—albeit with interruptions due to vertical tectonic movements and sea level changes—on the Niger delta, in the Chad basin, and in the coastal basins. These vast sedimentary basins contain a wide range of mineral resources, including petroleum and natural gas (the Niger delta being among the largest fields in the world), coal, phosphates, gypsum, uranium, and zinc.

Generally less resistant or thinner than the older sedimentary rocks, the Mesozoic and Cenozoic rocks do not form striking topographic features or underlie vast plains. Some of the sandstones, however, produce extensive scarps, such as the Tegama and Awka.

Since the Pan-African event, igneous activity has been spatially limited. Four occurrences of volcanic rocks are worthy of note, however. First, intrusions of basic and ultrabasic magma occurred as sills, plugs, and dikes in Sierra Leone, Liberia, Guinea, and Côte d'Ivoire during the early stages in the breakup of the ancient supercontinent of Gondwanaland (see below) and the opening of the Atlantic Ocean (200 to 175 million years ago). Today the thicker intrusions produce bold cliffs and small plateaus. Second, approximately 92 million years ago kimberlite dikes and plugs were intruded from the upper mantle, also in Sierra Leone, Guinea, and Liberia. Now deeply eroded, they were the source for the diamond placer deposits in those countries. Third, between 340 and 145 million years ago large caldera volcanoes were built in Niger and Nigeria along a distinct north–south axis. Most of the volcanic carapaces have since been eroded, and the distinctive circular and ring-shaped granite plutons that fed the volcanoes have been exposed as mountain and hill massifs. They are rich in cassiterite, and their erosion has generated tin placer deposits that are mined in Nigeria. Fourth, extensive volcanicity produced lava plateaus, volcanoes, plugs, craters, and fumaroles along the mountain belt extending northeast from Mount Cameroon, itself a complex of active and extinct volcanoes, through the beautiful Bambouto, Adamaoua, and Mambila Songola highlands, toward the Chad basin. Although starting about 25 million years ago, this volcanicity has been particularly active during the past one million years.

The last in the series of orogenic and crustal reactivation (deformation and metamorphism of preexisting rocks) phases of the West African shield, the enigmatic Pan-African event, involved convergence between the West African Plate and the Central Saharan Plate (which included the shield rocks of Togo, Benin, Niger, and Nigeria), with rock deformation, granitization, and mountain building. Since then the subcontinent has undergone only slow vertical tectonic movements; these have caused profound erosion and the gradual exposure of the deeper parts of the shield assemblages. Sediments from this erosion accumulated in the sedimentary covers described above. After the Pan-African event, Africa was part of a supercontinent called Gondwanaland, which also included South America, peninsular India, Antarctica, and Australia. About 175 million years ago Gondwanaland began to break up along the lines of the present continental coasts. Sedimentary basins and rift valleys developed along future separation zones. There were several extensive marine transgressions across the low-lying eastern parts of the West African region during the Cretaceous period, at the same time slow uplift dominated the western parts of the shield. Gradually the Atlantic Ocean widened and during the past 65 million years intensive weathering and erosion processes dominated most of the subcontinent.

Relief and drainage. Virtually the whole of western Africa lies below 5,000 feet (1,500 metres); most of the region lies below 1,500 feet and is dominated by plains. Isolated high plateaus and mountains are found in Nigeria, Togo, Guinea, Liberia, Côte d'Ivoire, Cameroon, and Sierra Leone. Smaller hills and ridges abound, especially on the crystalline craton rocks.

The river system is dominated by the Niger, which, rising barely 310 miles from the Atlantic coast in Guinea, flows northeast toward the desert before looping southeast and south through Niger and Nigeria. Other large systems include the Sénégal, Volta, and Benue. Numerous short

rivers flow to the Atlantic, and the Chad basin is the focus for inland rivers. River discharges are highly seasonal, especially in the northern areas.

The extensive erosional plains (planation surfaces), usually underlain by completely weathered rock (saprolite) 15 to 300 feet thick, are the result of long periods of weathering and erosion following pulses of tectonic uplift and subsidence. Four main planation surfaces have been recognized, each separated by rocky escarpments or hilly dissected country. The oldest and highest plains, well preserved in northern Nigeria, began forming at the beginning of the Cenozoic era and are underlain by the thickest saprolites, which often include a layer of iron and sometimes aluminum-rich duricrust. Most of western Africa, however, is made of younger planation surfaces that have formed during the past 25 million years. Depositional plains in areas of tectonic subsidence characterize the western and southwestern coastlands, the Niger delta and its lower valley, the Chad basin, and the subhumid lands bordering the Sahara desert.

Effects of weathering and erosion

Particularly resistant rock types give rise to isolated hills (inselbergs) whose prominence is enhanced by the monotony of the surrounding plains. Certain granite intrusions produce the striking dome-shaped bare hills called bornhardts; others are the more blocky koppies. Schists, banded ironstones, and quartzites are carved into steep-sided linear ridges, and hard sandstones and duricrusted saprolites produce escarpments, plateaus, and mesas.

In the humid rain forest belt, the plains are dominated by low, rounded hills and narrow, swampy valley floors eroded from thick porous saprolites. Landslides and deep, narrow ravines characterize the saprolite-blanketed higher hillslopes. In the drier savanna lands, valley floors tend to be wider and flatter and occasionally broken by ledges and low mesas capped by duricrust.

Two types of coasts dominate western Africa's ocean shoreline. Low, muddy coasts, with mangrove swamps and interconnecting tidal creeks, are found along major river deltas and along coasts where the offshore current is weak. Elsewhere are long, smooth, sandy beaches often backed by older, sandy barrier ridges and lagoons.

During the past 1.6 million years, the Quaternary period, global climates have changed frequently. In the colder periods western Africa was characterized by reduced rainfall, longer dry seasons, expansion of arid zones, and reduction in the extent of forested land. In the far north of the subcontinent are fossil sand dunes, relics of these drier periods when desert aridity extended south by up to 300 miles. The last of these arid periods was from 22,000 to 14,000 years ago. Virtually all the rain forests were then replaced by open savannas. The alluvial floodplains in the region were built when climates returned to present-day levels of humidity during the past 10,000 years.

Soils. Western African soil types are strongly controlled by their parent materials, topographic position, and climate. Consequently, the spatial distribution of the major soil types reflects the north–south climatic zonation, the distribution of the major geologic formations, and, at the local scale, their topographic conditions.

There are four primary regional soil classes. In the rain forests, where rainfall exceeds 60 inches annually, are deep, red and yellow-red ferrallitic soils. They show little horizoning (distinct layers of soil) and are friable and very porous. Composed of kaolinitic clays and dispersed iron oxides, they contain no weatherable minerals, have a low cation exchange capacity (CEC), or ability to hold and exchange cations (important to plant growth), and are inherently infertile. Any fertility comes from the organic matter content, and this is almost totally leached within two years of clearance for agriculture.

Primary soil classes

Associated with the savanna woodland zone and the zones with about 20 to 50 inches of rainfall, and occupying the greater part of the region, are ferruginous soils. These are usually less than six feet deep, and horizons are well developed with prominent iron oxide mottles and concretions and clay textures in the B horizons below the organic-rich topsoil. They contain a moderate-to-high reserve of weatherable minerals and have textural properties that vary with the parent material from which they devel-

oped, being generally sandy and free-draining over most of the crystalline and sedimentary formations.

Between the ferrallitic and ferruginous soils are a broad belt of ferrisols. These are less leached and slightly more fertile than the ferrallitics but less fertile than the ferruginous. They developed in association with the drier margins of the rain forests.

In areas with less than 20 inches of rainfall and associated with the northern Sudan savanna and the Sahel (Arabic *sāḥil:* "shore," referring to the region bordering the Sahara) savannas are the brown and reddish brown semiarid soils. Little leached, they contain free carbonates and chemically active clays and have a moderate to high CEC. Their fertility has supported many centuries of cultivation when supplemented by organic manure.

In addition to these four, several less extensive soils may be found. Eutrophic brown soils are developed on basaltic lavas and limestone rocks in the savanna regions. Their surface area is not great, but they are capable of sustained high yields when protected from erosion and supplemented by manure. The broad floodplains and coastal swamps contain immature hydromorphic soils. Although often high in their CEC, they are usually gleyed and seasonally waterlogged. In the Sahel within large depressions and formed from clay-rich materials are black vertisols. These are among the most fertile in western Africa, but they are difficult to till as they dry to a concretelike hardness in the dry season and turn into sticky, heavy muds in the wet seasons. Iron oxide crusts and pisolitic parent materials are also found in the savannas, and the soils found above them are thin, gravelly, and infertile.

Rainfall and Temperature Patterns in Western Africa

	Freetown	Lagos	Niamey
Annual rainfall (inches)	138	71	22
Rainfall in wettest month (inches)	37	17	7
Length of wet season (months with more than four inches)	7	6	2

Mean diurnal temperature range* in hottest month	9° (5°)	18° (10°)	34° (19°)

*Fahrenheit (Celsius)

Climate. Lying entirely within the tropics and sandwiched between the Sahara to the north and the equatorial Atlantic to the south, western Africa displays a gradual change in climate from hot, wet, and humid in the south to very hot and dry in the north. The climate is dominated by two air masses. One is derived from the quasi-permanent high-pressure cell generally located over the Sahara, from which are derived the hot, dusty northeast trades, or harmattans. In the winter months these winds occasionally extend over all of western Africa south to the coastlands. The other air mass is derived from a similar cell located over the tropical Atlantic. It is characteristically very humid and brings cloud cover, heavy rainfall, and high humidity to western Africa, which it progressively dominates from January to September. Separating these two air masses is the Intertropical Convergence Zone (ITCZ), and along it the denser humid southerly air penetrates beneath the dry easterly air.

Using these two air mass systems, western African weather can be described in terms of five north–south zones. The northernmost zone, zone A, lies beneath the dry easterlies and north of the ITCZ. Temperatures, insolation, and evaporation are high; humidity is low; skies are clear, but dusty. Next south is zone B, immediately south of the ITCZ, with high humidity, clear skies, high temperatures, and small, puffy cumulus clouds but no rain. Zone C has a thicker moist air system, and in it develop thunderstorms and line squalls caused by air pressure variations in the dry easterlies aloft and by excessive convective heating over uplands. The thunderstorms and line squalls move westward, covering hundreds of square miles and bringing high winds, intense rainfall and, occasionally, hailstones, and exciting lightning displays. Zone D, in the thickest part of the moist southwesterly air system, exhibits deep cloud cover, persistent and often heavy rainfall, high humidity, and lower temperatures. Zone E is characterized by high humidity and cumulus clouds but little rain. Subsiding dry air above the moist surface winds suppresses convective rainfall, and at the height of the wet season the southern coast of western Africa experiences a "little dry season." This weather zonation moves northward from January to September and retreats southward from September to December. The climate of any spot depends upon this seasonal migration of the weather zones.

Most areas in western Africa experience a single wet season, whose duration decreases northward from 11 to 12 months along the southwest coast to three months in the north. Annual total rainfall similarly decreases northward from more than 120 inches (3,000 millimetres) between Monrovia (Liberia) and Conakry (Guinea) on the southwest coast to about 20 inches between Dakar (Senegal), Mopti (Mali), and Niamey (Niger) in the north. Mount Cameroon exhibits the greatest total annual rainfall (greater than 150 inches) because of its orographic effect on the moisture-laden southwesterly winds. Along the southern coastlands there is a double wet season separated by the "little dry season" of July to September, and annual rainfall ranges from about 30 inches at Accra to more than 120 inches along the coast of Cameroon.

Largely because of the decreasing extent and duration of cloud cover, regional patterns of daily temperature maxima and diurnal ranges increase northward. At specific locations temperature characteristics vary with the seasonal passage of the ITCZ and its associated weather zones. Zones A and B bring higher and more extreme ranges, whereas zones C, D, and E are accompanied by lower and more even temperatures. These rainfall and temperature contrasts are illustrated in the Table using data for three towns—Freetown, Sierra Leone, on the southwest coast, with a single long and exceptionally wet season; Lagos, Nigeria, on the south coast, with a double wet season; and Niamey, Niger, in the drier, hotter north.

Plant and animal life. Vegetation in western Africa has been so strongly modified during centuries of cultivation, grazing, and burning that there are now few areas of untouched primary vegetation. Traditionally, most western African agriculture has involved abandoning cultivated ground after several years to enable soil fertility to be rebuilt by naturally regenerating vegetation. Fires—to clear land for cultivation, to bring on a new grass flush for cattle, to drive animals during hunts, or started by lightning—also have affected the composition of virtually

(marginal notes, right side:)
Five climate zones

Effects of cultivation on vegetation

all the vegetation north of the rain forests. Indeed, the extensive savanna woodlands are regarded as fire climax communities, and vegetation in small sites protected from fire and cultivation is quite different in morphology and composition from the bulk of the surrounding vegetation. Consequently, in the more sparsely populated regions there are vegetation communities that may be not unlike the original ones, but elsewhere the landscape is a mosaic of farmland, fallow land, grasslands, grasslands with bushes and trees, open woodlands with grassland, coppices of dense woods, and forest blocks.

The progressive northerly reduction in rainfall, humidity, and length of wet season, and increase in evaporation is associated with clear vegetation changes characterized by species composition and community morphology. Rain forest in the south is replaced in the north by several types of savanna woodland.

The tropical lowland rain forest is a species-rich community dominated by broad-leaved trees up to 200 feet high with slender unbranched, buttressed trunks. Saplings and ferns are numerous but the undergrowth is thin. The canopy carries climbing giant lianas and epiphytes. Many of the forest trees are commercially useful—*e.g.*, mahoganies, sapele, guarea, African walnut, iroko, utile, and obeche. This vegetation lies along the southern area between Cameroon and Sierra Leone, with the exception of a gap in southern Ghana. Large areas, however, have been cleared for agriculture. An impoverished but often denser secondary forest colonizes abandoned farmland. The brackish, muddy, tidal creeks of the coastlands support distinctive mangrove communities, and tall swamp forests or grasses, shrubs, ferns, and raphia palms grow in the freshwater swamps of the deltas and lagoons.

Originally the evergreen rain forest gradually merged, through an ecotone (transitional area) of mixed deciduous and evergreen forests, into the deciduous woodlands of the seasonal tropics. Today, however, the boundary between the rain forest and the savanna woodlands is very sharp and maintained by annual burning. The southernmost of the savanna woodland communities, called the Guinea savanna woodlands, is dominated by trees such as *Lophira, Terminalia,* and *Anogeissus;* fan palms; and tall tussocky grasses (*Hyparrhenia, Andropogon, Pennisetum* species) in the south. *Isoberlinia, Monotes,* and *Uapaca* characterize the northern parts. This formation extends into eastern

Sahelian landscape near Zinder, Niger, typical of the western Sudan.
A.G.E. FotoStock

Africa, where it is colloquially called Miombo woodland. Today the zone is a mosaic of grasslands with and without isolated trees and palms, riparian rain forest, and dense coppices of deciduous forest.

Farther north, where the dry season is six to eight months long, are the Sudan savanna woodlands, characterized by shorter grasses and fire-resistant but agriculturally useful trees with wide spreading crowns growing 25 to 50 feet tall, such as *Acacia albida,* shea butter, locust bean, kapok, red iron wood, and baobab. This belt has been densely populated for centuries, and the natural woodlands have been replaced by extensive grasslands with occasional trees. In both the Guinea and Sudan savannas most of the trees are contorted from repeated fire damage.

North of the Sudan zone are the more sparsely populated Sahel savanna woodlands, where the dry season is more than eight months and cultivation is restricted to valley floors. Low, umbrella-shaped deciduous thorn trees (such as the *Acacia seyal*) and shrubs (such as *Commiphora africana*), succulents, and short, tussocky grasses give a distinctive vegetation strongly modified by burning for seminomadic cattle grazing.

The rain forests and the savanna woodlands are ecologically very different. The savannas have far less biomass, slower rates of nutrient cycling, fewer species and lifeforms, and harsher microclimates than the forests. Nutrient cycling is accomplished mainly by burning and macrofauna (termites and ants) in the savanna woodlands and by bacteria, fungi, worms, and termites in the rain forests.

Long settled, and in some areas densely populated, western Africa is famed not for its wild animals but for its large flocks and herds of sheep, goats, and cattle, primarily in the savannas. Most of the indigenous larger **Dis-** wild animals—lions, leopards, cheetahs, serval, crocodiles, **appearance** rhinoceroses, giraffes, elephants, antelopes, gazelles, bush- **of wild** bucks, buffaloes, and oryx—have been hunted to, or al- **animals** most to, extinction during the past 200 years, and the wild dogs, hyenas, and jackals that were dependent upon them have also largely disappeared. Most countries now have conservation policies, and in national wildlife or game parks, such as at Yankari, Nigeria, some of the formerly more common species can be observed. Smaller species—

monkeys, chimpanzees. baboons, wildcats, duikers, hogs, cane and great rats, hyraxes, lizards, iguanas, and snakes— have not been so severely affected. Bird life, both resident and migrant species, is diverse and abundant, often to the extent of being an agricultural pest. Ants, termites, and insects are ubiquitous and play a fundamental role in plant nutrient cycling. Termite mound nests are a common and distinctive sight in the savanna areas.   (M.B.T.)

TRADITIONAL CULTURES

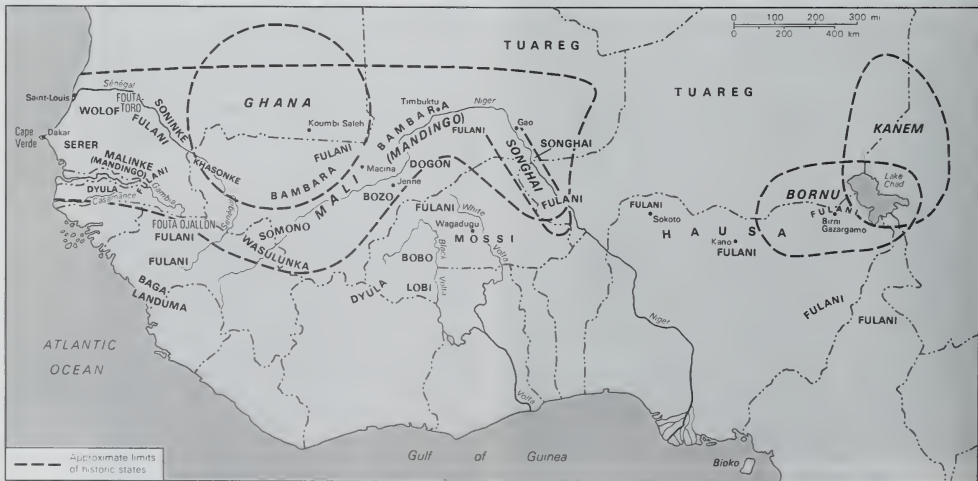
People and languages

The western Sudan. The major ethnic groups today, as shown on the accompanying map, are the following: the Wolof of Senegal, the Serer to the south, and the Mande-speaking peoples to the east, comprising such subgroups as the Malinke, the Khasonke, the Bambara (Banmana), the Wasulunka, the Dyula, the Marka, and the Soninke (Serahuli). The Songhai are located largely in the region south of Timbuktu along the Niger, the Mossi are in the Volta basin, and a variety of smaller groups, such as the Dogon, Lobi, and Bobo, survive within the great bend of the Niger. Other small groups, such as the Diola (Jola), Landuma, and Baga, are to the southwest. The Hausa are concentrated largely in northern Nigeria, though they are scattered in all the major trade centres of western Africa. The Fulani (Fulbe or Peul) are distributed widely from the west Atlantic coast to Chad and Cameroon, though particularly concentrated in Senegal, Guinea, and northern Nigeria.

The continuous movements of people over the centuries have led to a complicated pattern of languages, but it is now held by some authorities that most of the languages should be considered as branches of one great Niger-Congo family. This would include the Mande, Voltaic, Kwa, Adamawa-Eastern, and West-Atlantic groups. The last includes such varied languages as Wolof, Serer, Fulani, and Diola. Linked to the Niger-Congo are the Kordofanian languages spoken in the area of the Nuba Hills. Other major families that have been distinguished are the Nilo-Saharan group, which includes Songhai, and the Afro-Asiatic, which comprises Ancient Egyptian, Berber, Cushite, and Hausa, among others. French is the language of communication among the elite of most nations of the western Sudan—namely, Senegal, Mali, Niger, Chad, and Guinea—but English is used in The Gambia, Ghana, and Nigeria.

Traditional culture patterns. Natural conditions in the Sudanic zone—drought, crop failures, epidemics of human and animal diseases—cause a great deal of uncertainty in peoples' lives, and they turn to the supernatural either in traditional rituals or in the Islāmic faith for reassurance and hope in time of trouble and the possibility of a greater reward in the next world. Life is also affected by the rhythm of the seasons, with a great contrast between the rainy season, the time of intense work on the farms, and the dry season, when the pace of life is slower. People must adjust their pace to natural conditions to gain the best advantages from them and must also be in harmony with the unseen powers behind them. Conditions may often be harsh, but farm work, though hard, is an honourable occupation, and the average inhabitant remains surprisingly optimistic and enjoys life to the full. Some of this feeling derives from the fact that a person does not face trouble alone but as a member of a group, linked to others by a complicated system of obligations—to kinsfolk, neighbours, and members of the same age group—maintained by constant visits, economic exchange, and mutual help at ceremonies. Everyone also feels links with the ancestors of the tribe. In general, the philosophy is one of bearing troubles patiently.

Social organization. In the period from about AD 500 to 1470 the Sudanic zone was characterized by the rise and fall of a series of states and empires. The first to achieve eminence was Ghana (not to be confused with the modern state of that name), situated between the Sénégal and Niger rivers. It derived great wealth from trade in gold from the south and salt from the mines of the Sahara to the north. Ruins excavated in Koumbi Saleh are believed to be its capital, a town that could have contained 20,000 inhabitants. Ghana's power declined during the 11th century after nearly 20 years of attacks from the Almoravids, a Berber military and religious order from the Sahara, devoted to converting nonbelievers to Islām. The Mande-speaking people of Mali, on the Niger, developed the next great state, expanding rapidly in the mid-13th century, absorbing Ghana, and then gaining power over the trading cities of Timbuktu and Gao at the end of the major trans-Saharan trade routes. In the early 14th century the emperor of Mali, Mansa Mūsā, visited Egypt and Mecca. A large number of Arab scholars—teachers, lawyers, architects, doctors—established themselves in Mali at this time. After the death of Mansa Mūsā the empire began to break up. The city-state of Gao, under the Songhai, broke away toward the end of the 14th century and by the early 16th century had taken over control of the central region of the western Sudan. The power of Gao was extended over Timbuktu and Djenné, which were then at

Local and territorial organization


Distribution of the peoples of the western Sudan and locations of major historic states.

their height as centres of trade, learning, and religion. The power of the Songhai, however, was broken in 1591 by an invading army from Morocco, whose firearms provided a great advantage over the swords and spears of the Songhai.

Farther east, the Chad region received various waves of immigrants—hunters, fishermen, and farmers who introduced weaving, bronze work, and pottery. They came under the influence of two states: that of Kanem, north and east of Lake Chad, which was powerful between the 11th century (when Islām began to make itself felt) and the 15th; and that of Bornu, to the west of Lake Chad, the dominant state in the 16th and 17th centuries. Bornu's army had a strong cavalry force, wore chain mail, quilted armour, and iron helmets, and retained its medieval splendour down to the 19th century, with something of its former pageantry still to be seen at Islāmic festivals.

Patterns of
leadership

Society in all of these states was highly stratified, with a powerful ruling class controlling the wealth. A central ruler appointed regional governors or obtained the allegiance of outlying vassal chiefs, who were obliged to pay annual tribute and supply labour as needed. Well-organized armies both suppressed rebellion within the state and defended the boundaries against external enemies. War captives became slaves and performed much of the physical labour, carrying loads and working on farms. Islāmic religious teachers often formed part of the ruler's court, and gradually the people were converted to Islām. The ruler himself often filled a sacred role, as it was believed that the vital forces of the kingdom—rain, good harvests, and fertility—depended on him. The rulers were patrons of various arts and crafts, and the courts included musicians, praise singers, storytellers, goldsmiths, leatherworkers, and so on. Men of slave origin could rise to high rank as court officials and enjoy power over the freeborn.

Traditions reflecting the greatness of the former states have been handed down in songs and legends, and traces of old social patterns are to be seen in the behaviour of present-day chiefs. But the average person's primary allegiance is to the village rather than to a larger unit, and people are concerned with the ruler only when they have a court case or must pay taxes.

Villages are divided into wards or quarters, the nucleus of each ward being the descendants of an original settler, though as time goes by later settlers are absorbed. Often there is a meeting place for the men of the ward. Disputes within the village are commonly settled by the village head and the elders at a general meeting, or moot, in which the aim is to permit the parties to a dispute to state their grievances freely. The elders then arbitrate and seek to restore harmony and achieve a settlement, the meeting concluding with the group either praying together or sharing food or kola nuts imported from the south.

The village head is drawn from the clan that was the first to settle in an area and clear land. In general, rights of land ownership are determined in the first place by the act of clearing, and then the descendants of this person have the right of usage. Land is held in units large enough to support a family and is not fragmented. Where land is short, people break away and found new settlements; and migration also tends to occur under political pressure.

The pattern of descent since the coming of Islām has generally emphasized the male line (patrilineal descent), though links with relatives on the mother's side are also important—the mother's brother, for example, always giving help and support to his nephews and nieces. In families of slave origin, ties through the female line remain strong because the owner of the mother also owned the children born to her. In pre-Islāmic times, rights to rule could be transmitted through the female line, though the incumbent had to be male. People recognize kin groups in which they know the exact blood relationships (lineages) and that share rights over land and other privileges and obligations; but they also feel themselves related to larger groups (clans), descended from remote ancestors who bear the same name or observe the same ritual prohibitions.

Family
and
kinship
patterns

In arrangements for marriage the family of the groom pays the family of the bride a sum of money known as the bride-price, which is returnable if the marriage fails through the fault of the wife. Ordinarily parents use the money received for a daughter to pay for a wife for a son. Households are normally larger than the nuclear family of husband and wife, for polygyny is permitted. The general pattern, however, is for each wife to have her own house, in which she cooks for herself and her children, taking her turn to cook for and sleep with her husband (though when a woman is pregnant or suckling a child she refrains from intercourse with her husband). A young widow will remarry, usually the brother of her deceased husband (the institution of the levirate), thus maintaining the link between the two families. If a marriage payment has been made and the fiancée dies, then a sister will replace her (the sororate). A widow who is old will often nominally remarry, but in practice be supported by her children, and often will stay with a son. The strongest emotional ties are not so much between husband and wife as between mother and children. An affectionate type of joking prevails between grandparents and grandchildren, and at weaning time small children are often sent to stay with maternal grandparents. A joking relationship also holds between cross-cousins (children of siblings of the opposite sex), and a cross-cousin has specific roles at naming, marriage, and burial rites.

In African cultures ties between mother and child are extremely close. From birth to 15 months the child is carried on the mother's back; the child is fed at the slightest demand; and the mother plays with, sings to, and cuddles the child at every opportunity. Adults in general like children, hold them, protect them, and play with them. Grandmothers, in particular, are indulgent. The result is that the child grows up feeling valued and loved. There is, however, the very real threat of illness and death. Infant mortality, caused mainly by malaria, is high, and childhood illnesses—measles, whooping cough, influenza, pneumonia, and meningitis—take a heavy toll up to the age of five.

Socialization and education

Children begin to take part in the work patterns of the community at an early age and are not as a rule kept separate from adults. Small children imitate adult activities in their games and then begin to undertake the lighter tasks. Girls help to pound grain with pestle and mortar, draw water, use winnowing baskets, fetch firewood, and so on. Boys drive off birds and monkeys from the farms and then help in weeding as they become older, until finally they are able to undertake a young man's share of cultivation. Among cattle-keeping groups, boys learn their adult roles by handling calves.

Initiation ceremonies mark the transformation from the status of child to that of adult. For males the ceremonies are generally associated with either circumcision (though many Muslims now have their sons circumcised in infancy) or, in some areas, scarification; in the past, death through infection was not uncommon, though now modern antiseptics may be used. The ceremonies involve both a physical separation, the initiates living outside the village in the bush, and a ritual death, followed by rebirth when they return to village life. During initiation they are harshly punished for their faults (sometimes for crimes committed before initiation, such as stealing); they are instructed in the traditions of their society and learn secret means of male communication, unknown to women or children. The initiates remain in seclusion for a period varying from several weeks to several months, and those who have gone through initiation together, irrespective of their age, retain close ties throughout life. In many societies there is also female initiation involving clitoridectomy. While in seclusion the initiates receive training for their future marital role.

Initiation ceremonies

There is a marked division of labour between the sexes: the women are concerned with preparing food, caring for the children, drawing water, washing clothes, making pottery, dyeing cloth, gathering leaves, fruits, and firewood, and so on, whereas men are concerned with looking after large animals such as cattle, horses, donkeys, and large sheep and with hunting, clearing land for agriculture, fishing, butchering, house and fence building, woodcarving, leatherworking, and smithing. Carding cotton and spinning are women's work; weaving is men's. Women have their own meeting place at the well or stream; men have a

place in a village square. The farming tools used are often different for men and women.

Stratification

Although egalitarian relationships are found in many non-Islāmic groups, such as the Diola and some pastoral Fulani, a system of social stratification is characteristic of most western Sudanic peoples. The essential pattern consists of such categories as (1) the royal families, often deriving from foreign conquering elements; (2) the nobles, members of high-ranking lineages who constitute the military leaders or provincial governors and who may have the power of electing the ruler from among suitable royal candidates; (3) the freeborn, who are landowners and farmers and sometimes traders; (4) the people of slave origin, who are objects of social discrimination or differentiation despite official abolition of the slave trade; and (5) the casted craftsmen, which include musicians, praise singers, professional storytellers and entertainers, smiths (whether blacksmiths, goldsmiths, or silversmiths), leatherworkers, and certain types of woodworkers. These craftsmen can marry only within their own category, cannot lose their status even if they abandon their trade, and are looked down upon by the freeborn, even though they may be richer and perform crucial services. The women of various caste groups are often expert hairdressers and tattooers. Islāmic scholars and their families are accorded high prestige.

Officials appointed by rulers could be either freeborn or of slave origin, with the result that "slaves" often came to enjoy greater power than the freeborn. Today there is also differentiation based on wealth acquired by trade and on status in positions of government service. Since independence from colonial rule, those who have attained prominence in political parties or the military have reached the chief positions of power.

Settlement patterns and housing

Economic systems. The characteristic settlement is a concentrated village consisting of fenced-off clusters of houses (compounds) occupied by members of a lineage and their spouses. Because for hundreds of years villagers led an uncertain life, liable to ravage by invaders and slave traders, many villages were built on sites afforded some protection by rivers or fortified by earthen walls. These old fortifications have almost all disappeared except for the great walled cities of northern Nigeria. The general trend during the 20th century has been for smaller and more widely dispersed villages, as people have cleared more land for agriculture, but as a result of periods of drought in the 1970s and '80s many people have resettled in the larger urban centres.

Among the Wolof the average population of a village is only about 100, and the compounds are built around an open village square. In the past the houses were generally circular, with walls of either millet stalk or reed, but now a rectangular form is more common, with mud walls and roofing often of imported zinc or aluminum sheeting. Fulani settlements tend to be even smaller and consist of temporary huts with walls of reed or of matting woven from grass. Malinke villages, on the other hand, tend to be larger, with some 1,000 to 2,000 people; the houses are generally mud-walled with a conical roof thatched with grass. In the north the Tuareg are tent dwellers. In general, the most common western Sudanic house is circular, but the square or rectangular form is not necessarily recent, for excavations of old towns in ancient Ghana have revealed rectangular houses.

In addition to the farming villages, the western Sudan is characterized by very large towns, either the capitals of the old states or trading towns at the southern end of the various trans-Saharan trade routes, such as Kano, Nigeria, and Timbuktu, Mali. There, architecture is often influenced by North African forms, mosques and fortresses in particular being designed after Arab patterns. At present, with the availability of imported sheeting for roofs and locally manufactured cement, richer people are building more permanent houses that are square or rectangular.

Patterns of agriculture

Few traces are now to be found either of purely hunting and gathering groups or of fishing communities, except for such peoples as the Somono and Bozo fishermen of the Niger. Most inhabitants are agriculturalists, dependent on the cultivation of such crops as millet and sorghum for food and peanuts (groundnuts) for cash. The system is one of shifting cultivation: the savanna land is cleared by ax and cutlass, the residue burned, and the crops planted. The hardest work is the continuous backbreaking struggle against weeds, the principal tool being a small hand hoe, and when the crops are ripening, they need to be protected against swarms of birds. Crop rotation is customary, but the soil nevertheless becomes exhausted after several years of cultivation and is then allowed to revert to bush. Only patches around the villages, fertilized by household rubbish, animal manure, and so on, can be kept under continuous cultivation. In such patches tomatoes, peppers, beans, eggplants, maize, and condiments can be grown. On good soils cotton cultivation is possible.

The single rainy season demands a considerable amount of extremely hard work in a very short period of time, and irregularities in the rainfall, whether drought or cloudburst, can cause crop damage and a food shortage. Farmers suffered losses through plagues of locusts, and despite international efforts at control these plagues still occur. People supplement the cultivated crops, particularly in times of shortage, with wild fruits and roots. The fruits of the baobab (*Adansonia digitata*), nete (*Parkia biglobosa*), and tamarind (*Tamarindus indica*) are particularly important, while over much of the more northern zone the shea-butter tree (*Butyrospermum parkii*) is a source of vegetable oil. In regions with a more abundant water supply, like the Gambia and Casamance valleys, rice is the dominant food crop.

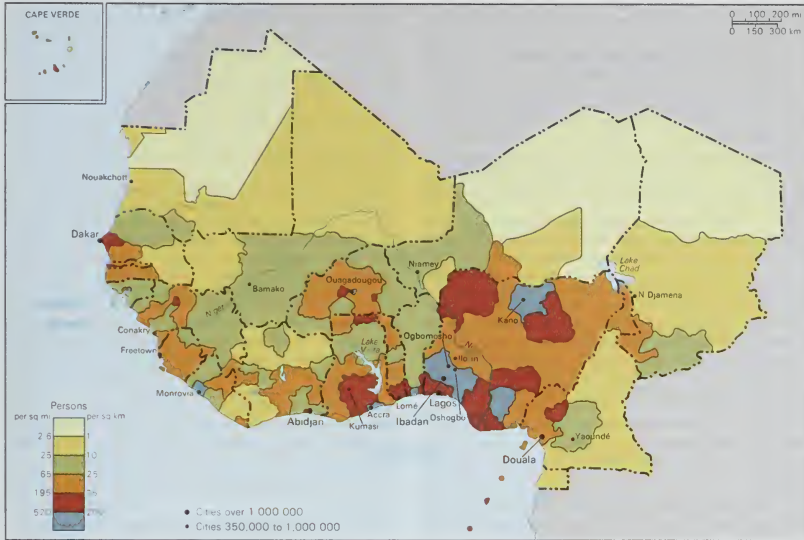
The dry season is a period devoted to visiting friends, trading, building houses and making repairs, engaging in arts and crafts (pottery, mats, textiles, basketry), and participating in such ceremonial events as marriages and initiation ceremonies.

Another important life-style is that of the pastoralists. The central region of the western Sudan, with its extensive grasslands, provides opportunities for raising large herds of cattle. The Fulani are the main cattle owners and are found from the west Atlantic coast to Chad and Cameroon. Some are entirely nomadic, living in temporary shelters and moving between wet-season and dry-season grazing areas. Others stay in fixed villages, build more permanent houses, engage in farming—producing excellent crops because of the cattle manure—and still maintain large herds of cattle. The men are concerned with the care of animals, determining the time for movement, selecting grazing areas, and seeing that the animals are watered. Women's occupations include domestic tasks, drawing water for household use, collecting firewood, cooking, and processing and selling milk. Both the watering places and markets in the towns are important meeting places where the Fulani exchange vital information about the state of pastures, water, animal diseases, and politics. The cattle population has increased rapidly as the result of inoculations against such diseases as rinderpest, but the Fulani feel personally attached to their cattle, in which their wealth and well-being are involved, and are reluctant to sell animals for slaughter.

Pastoralism

The western Sudan has always been a highway and crossroads for long-distance trading. Today, manufactured goods entering the Atlantic ports, including cloth, medicines, and transistor radios, are taken inland. Sudanese traders travel to Sierra Leone, Ghana, and the Congo basin to deal in diamonds, which eventually find their way to the Middle East. Gold still crosses the Sahara to North Africa, and salt from the Saharan mines comes by camel caravan to the Niger River. Caffeine-containing kola nuts from the Guinea Coast rain forests are transported north in large quantities; they are in great demand among the farmers for assuaging hunger and thirst and for use in ritual and sociable contexts. Hausa leatherwork is widely traded.

Exchange system

The major trade routes across the Sahara are supplemented by lateral routes along the Niger and along the Sénégal and Gambia river valleys. For certain commodities a system of direct barter prevailed; Fulani herdsmen, for example, exchanged milk and butter for grain. Along the Niger is a substantial trade in dried fish, either bartered for grain or sold for cash.


Population density of western Africa.

Belief systems. Indigenous systems of belief unaffected by Islām involved the concept of the essential unity of the visible and invisible worlds, humanity being accorded the dominant position in the system. Forces in plants, animals, and minerals are made known to humans through ancestors and can be used for either good or evil, humans having the moral responsibility for making the choice. Living persons are a continuation of the life stream of the first beings. Ancestors watch over the living and act as intermediaries between them and the creator of the universe, who is now remote from humans, even though his power is supreme. The ancestors indicate their wishes through dreams sent to the elders, while the living communicate with the ancestors through prayer and sacrifice, the blood of sacrificed animals setting in motion certain latent spiritual forces. The spirit world is also evoked by persons wearing carved masks during special ceremonies; associated dances and drumming cleanse, reinvigorate, and protect the community. The masks themselves are the abode of spirits, and carvers feel inspired by supernatural powers.

Religious beliefs reinforce the traditional values of society, for it is believed that lack of harmony in the community and breaches of traditional law and custom are followed by such disasters as drought, disease, and crop failure. Society is threatened by forces outside the community—evil spirits that are believed to cause mental disorders and physical abnormalities—and by people inside the community in whom evil grows—witches, who can cause harm to both human beings and crops through a witch substance inside them, and sorcerers, who perform deliberate acts of evil magic. Charms are worn and protective devices set up to guard against such dangers, while diviners seek to detect both witches and sorcerers. Diviners are consulted by individuals with problems; it is their role to trace the causes of troubles, using such techniques as casting cowrie shells or reading patterns in sand to see into the spiritual world, and then to indicate the proper measures to be taken. Diviners provide treatment at the physical level by prescribing herbs and medicines, at the psychological level by listening to confessions and providing reassurance, and at the social level by trying to disperse tensions between individuals.

Islām has spread widely throughout the western Sudan, and between 60 and 70 percent of the people are nominally Muslim. Most attend services at the mosques, observe Ramadān (the month of fasting), say the daily prayers, and give alms generously; and a few are able to make the pilgrimage to Mecca. Wherever Islām is the dominant faith, Muslim religious teachers have taken over the role of traditional diviners in determining the causes of troubles, and they provide remedies in conformity with Islāmic patterns. Children are given religious instruction in which they learn the prayers, recite long passages from the Qur'ān, and acquire the rudiments of Arabic writing. The traditional ritual dances and masked performances are gradually disappearing or have been greatly modified as a result of opposition from Muslim teachers. Nevertheless, many of the traditional beliefs about spiritual beings still remain relatively unchanged in people's minds. Christianity has had little effect in the western Sudan, except marginally in the coastal cities of Senegal and The Gambia.

Oral literature. The region is extremely rich in oral literature: proverbs; myths of origin; animal stories in which the lion, hyena, and hare play prominent parts; epics; and tales about people (neglected orphans, disobedient children, the rivalry of co-wives, jealous husbands, deceitful wives, unjust rulers) and about supernatural forces (encounters with good and evil spirits, the terrible deeds of witches and sorcerers). Narration involves both entertainment and education, for the young learn something of the values of the community and acquire knowledge of approved and disapproved behaviour. There is always a high degree of audience involvement, the listeners either replying to the narrator's questions or singing the rhythmical choruses that form part of the narrative style. Storytellers act the roles of the various characters with great effectiveness, and the narration becomes a highly rhythmical performance leading up to a dramatic climax.

Evolution of the cultures. In general, the western Sudan has been slow to change, largely because of long distances and problems of communication and because of the generally low level of income throughout the area. Migrants from the interior have gone south to work in the mines and cocoa plantations of Ghana or in the coffee, cocoa, and banana plantations of Côte d'Ivoire or to cultivate peanuts in the Sénégal and the Casamance river valleys; but for the most part they revert to traditional ways when they return home.

Animistic beliefs

Influences of Islām

The new town dwellers

In moving to the cities and towns of the coastal zone, migrants who are from the same ethnic group or village have a tendency to live in the same area of town and tend to spend their leisure time together. Disputes that arise between people of the same ethnic group are ordinarily settled by the elders of that group according to traditional law and custom and are not taken to the state court. Voluntary associations are formed for mutual aid and entertainment.

In general, Islāmic influence has continued to spread slowly and steadily among animistic groups, for a Muslim has higher status than an animist outside his own community.

Change in agriculture has been slight. Mechanized agricultural projects have usually been unsuccessful because of the high costs of maintaining machinery. In Senegal, The Gambia, Mali, and Niger, light plows and weeding equipment drawn by donkeys, horses, and oxen have become popular and have led to an increase in the production of the cash crop, peanuts (groundnuts). The growth of cooperative societies has enabled farmers to receive greater cash benefits, and the improvement of roads and the increase in motor transport have made the marketing of produce easier. Gains have been offset by years of low rainfall, however.

In Niger and Chad, spectacular success has followed programs of water prospecting. Artesian water is now tapped by boreholes, and artificial water holes have been created, designed to store water during the dry season. This has enabled the seminomadic cattle owners to settle and make use of the rich pastureland available, the limiting factor previously being the lack of water for cattle. In the 1970s and '80s, however, recurring droughts caused heavy loss of livestock and led to desertification of overexploited marginal lands.   (D.P.Ga.)

The Guinea Coast.   Guinea is a term used originally for the coastlands and adjacent forests of western Africa between the Republic of Guinea on the west and Equatorial Guinea on the east, including the whole, or the southern parts, of Guinea-Bissau, Sierra Leone, Liberia, Côte d'Ivoire, Ghana, Togo, Benin, Nigeria, and Cameroon. There have been conflicting accounts of the derivation of the name Guinea, but it would seem to be a version of the Berber word *aguinaw,* or *gnawa,* meaning "black man," or "Negro."

The environment and the people.   In western Africa, in the general absence of major mountainous areas, natural regions are determined primarily by climate and vegetation, and the Guinea Coast societies are those that have in the past been associated with the equatorial forest zone. This forest has long been cleared for agriculture in some areas and has been subject to increasing and widespread threat over recent decades, but it is the natural vegetation

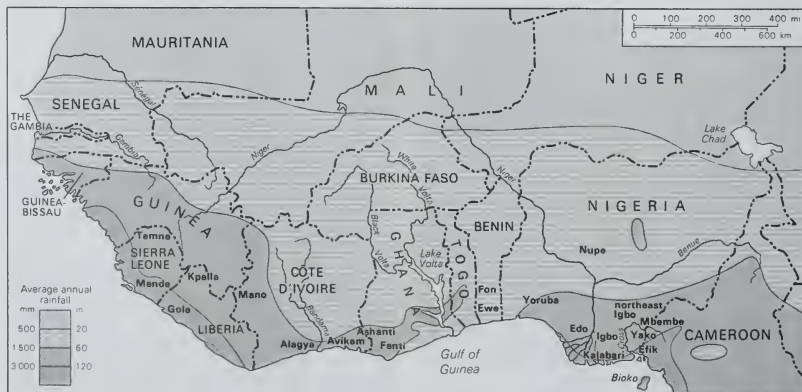
of most districts within 100 miles of the coast. In the east, heavy forest formerly extended from the borders of the Cameroon highlands to the area west of the Niger River. In the west, forest stretched from Sierra Leone to western Ghana. Between these two belts of forest there is a drier region, where for centuries tree cover has been thin; once cleared for farming the forest does not regenerate, and even areas left fallow for long periods remain as grassland. Societies in this area, while culturally similar to true forest societies, have historically been different in significant ways.

The forest greatly influenced the cultural development of the Guinea Coast by affecting the movements of peoples and the development of agriculture and commerce. People occupied the forest areas relatively late because farming there had to await the development of suitable tools and crops. Iron axes are needed to clear equatorial forests and only with the introduction of the shade-tolerant crops—the plantain and the cocoyam (taro and eddo), brought from Asia in the 9th century AD—could forest farming become an economic alternative to hunting and gathering. Moreover, until recently forest farming did not include animal husbandry, for the forest harboured species of tsetse fly that are particularly dangerous to cattle and horses. This had advantages for the forest people, however, because the tsetse fly and the dense vegetation protected them from marauding cavalry. Gradually the forest gave its inhabitants commercial advantages: kola nuts and, later, palm oil were so highly desired by distant peoples that traders by sea, and overland from the north, were drawn to the Guinea Coast.

The cultural significance of the original forest environment is shown even today in the linguistic map of western Africa. In detail there are many different languages in the forest area, some spoken by millions, some by a few thousand people. What is striking, however, is that the boundaries between the major language families roughly coincide with the old boundaries of the forest. Only in the extreme east does this clear division disappear. The linguistic division between the forest societies and the hinterland is good evidence for the long historical distinctiveness of the Guinea Coast cultures.

Cultural patterns.   This section cannot deal individually with all the groups in the area but only the more important or better-studied groups, for Guinea Coast societies vary enormously. Today many similarities are due to patterns of development in the colonial and postcolonial periods; nevertheless, precolonial variations still show themselves. This is true even in such obvious ways as population densities and types of settlement away from modern cities. Even within a small area, such as southeastern Nigeria, great variations exist. Prior to the Biafran war (1967–70) in certain Igbo (Ibo) areas there were 700 or more peo-

Cultural effects of the forest

Language distribution


Distribution of peoples and of rainfall in the Guinea Coast region.

ple per square mile (270 or more per square kilometre), whereas in the equally fertile forest hinterland of the Cross River densities were well under 100 people per square mile. Moreover, the Igbo settlements were characteristically spread out through their cultivated lands, whereas the Cross River peoples to the east of the Igbo lived in large nucleated villages. To the west of the Igbo, the Yoruba built in precolonial times some of the largest indigenous towns in Africa.

Interplay of environmental and historical influences

Such differences are usually caused by the complex interplay of environmental and cultural factors and historical contingency. Even in the choice of crops, which might seem to be more or less dictated by physical conditions, culture is very significant. It is true that in the eastern, tuber-growing areas the choice between one tuber and another may be determined ultimately by environmental factors. For example, the modern selection of cassava rather than yams is usually the result of the greater ability of cassava to tolerate depleted soils. There is a major crop boundary, however, roughly corresponding to a linguistic boundary along the Bandama River in Côte d'Ivoire; to the west rice is the staple crop but to the east tubers are the staple. This seems clear evidence of the significance of cultural choice. The importance of culture has also been shown by recent work on the agricultural skills of local peasants that has shed light on the ingenuity with which indigenous farmers develop new strains of preferred crops and adapt their techniques in order to get reasonable yields even under adverse conditions. Their techniques are often clearly superior to those advocated by official development agencies.

Historical background of trade and politics. The more complex the cultural patterns the more complex is the interplay of environmental factors and historical contingency behind them. The evidence is to be found in the political variations of the indigenous units of the Guinea Coast societies. At the end of the 19th century there existed tiny, independent political groups whose inhabitants had, for many purposes, solved the Hobbesian puzzle of how to avoid the "warre" of all against all without having recourse to the development of the state. At the same time there also existed powerful kingdoms. Some were of medieval foundation, and some had been developed in recent centuries, but the rulers of the largest held sway over hundreds of thousands of people. Environmental factors were obviously of significance in influencing political growth. The authority of a central government depends on the "message-delay" time involved in conveying commands to the periphery of the state. In the forest, where riding horses could not be kept and passage on all but the largest rivers was repeatedly blocked by huge fallen trees, political power might depend, as in 19th-century Asante (Ashanti), on enormous efforts put into keeping roads open for runners. The success of some of these states is particularly notable for the triumph of human ingenuity over adverse natural conditions.

Shift from Arab to European trade

Before the end of the 15th century, most of the region's external contacts were made through the savanna kingdoms to the north, whose merchants wanted slaves, gold, and kola nuts (a stimulant lawful for Muslims). From the end of the 15th century, however, the interests of the Guinea Coast peoples were partly reoriented toward trade with European merchants, who sought successively gold, slaves, and palm oil. European trade was significant partly because, unlike the northern trade, it was controlled within the Guinea area entirely by local people. Europeans were prevented from penetrating inland by climate, disease, and the express action of African authorities. The merchants at the coast provided inducements to sell; how their wants were supplied was a matter for local traders. These overseas merchants were also significant because of the nature of the goods they brought to sell. They were mainly consumer goods, but they also included such capital goods as iron, guns, and gunpowder, and these gradually introduced a crucial new factor into local warfare. Political authorities were forced into trade because it became militarily vital to acquire the new weapons. Even imported consumer goods had a political significance, for it was normally the political authorities, able to tax European

merchants and the local traders, who could acquire most goods. They thus had the best resources with which to exert general influence; consequently new power was put into their hands with important political consequences.

The development of Guinea Coast societies was radically influenced by the nature of their exports, especially the slaves. Slave trading did not everywhere lead to raiding, but where it did it led to changes in military and political organization. In Dahomey a strong government sent its army to raid slaves in every dry season; in Yoruba areas one factor in the violent relations between the city-states in the 18th and 19th centuries was probably their involvement in the trade, and new political forms were bred in response to this situation. Wherever war captives were traded as slaves, those central authorities who controlled captives developed an economic advantage over their rivals.

In the 19th century palm oil gradually became the most important Guinea Coast export because of its increased use as an industrial lubricant and because European humanitarians were successful in applying political pressure on their governments, especially the British, to end overseas transport of slaves. Nevertheless, slave dealing and raiding remained important internally throughout the century. Even when slave exports declined, the growing palm-oil traffic in itself stimulated these activities, for the transport of the bulky oil required slaves to paddle the canoe transports or to headload the oil to the ports. Moreover, a trader using many men to transport oil needed others, often slaves, to produce food for them; thus, slaves were important economically and politically to the Mende of Sierra Leone in the west and the Fanti (Fante), Dahomean, Yoruba, Niger delta, and Efik peoples in the south.

Effects of the slave and palm-oil trade

The growth of the palm-oil trade brought other economic and political changes. African traders exporting palm oil needed more capital than slave traders did, because slaves transported themselves and worked while awaiting shipment, whereas oil was expensive to transport and constituted idle capital while at the ports. An unanticipated result of the change to the oil trade was, therefore, that the exporters, needing capital, became increasingly reliant on European firms that advanced them goods on credit and therefore took increasing interest in local political affairs. This was one factor leading to colonialism. Paradoxically, in the rural areas many men who could never have been slave traders could easily gather and sell palm produce. Apart from the exceptional case of Dahomey, where most palm oil came from large government-fostered plantations, oil was drawn mainly from the fruit of trees growing naturally in the bush. In the eastern forest areas especially, participation in this production and trade was very general.

By the end of the 19th century a network of local markets had been developed over much of the hinterland of the Guinea Coast. The great centralized kingdoms were naturally associated with great trade routes, but there is evidence that traders were protected by the common interest of many people—and almost all political authorites—that the routes should be kept open. It is remarkable that for the most part, even in the absence of strong governments and in areas where adjacent peoples might be regarded as fair game for attacks, the accredited trader passed unharmed; appropriate punishment was dealt out by local authorities to any person who robbed or injured them.

Markets and traders

Kingdoms and chiefdoms of Guinea. Although trade could flow across political boundaries, the political development of western African societies was much influenced by the growth of trade and through the warfare and the struggle for trade routes that accompanied it. Where trade was limited, most political units seem to have remained weak and small in scale. This was true in the earlier part of the 19th century in much of the area of Sierra Leone and Liberia and is a major reason that it was possible to settle freed slaves there without their being dominated by indigenous powers. Later, however, hinterland Mende tribes, located in rich oil-palm areas, fought for the control of trade routes and developed into more centralized groups under warrior chiefs. At the other end of the western forest, and at the other extreme as regards trade, the

Asante Confederation of kin-based states developed much earlier and quite differently. The area had early commercial importance in the northern trade as a source of gold and of the best kola nuts. From the 17th century the Asante exploited their gold resources, which were easily made a government monopoly, in order to gain local control over the import of firearms. Extending their influence over their immediate neighbours by diplomacy and over those more distant by warfare, they eventually subjugated peoples as far southeast as Accra, on the coast, and as far north as the savanna. It has been shown that in the 19th century the authorities—with remarkable insight into their own social structure, which was based on matrilineal clans—created a semiprofessional civil service in which offices were passed from father to son; this ensured that new officials were trained but that the offices escaped the clutches of the major kin groups.

In the eastern forest, northwest of the Niger delta, was the kingdom of Benin, whose rulers claimed to have come originally from the Yoruba area. It was of medieval origin and was so well established in the late 15th century that the king of Benin sent an emissary to the king of Portugal, who in turn sent missionaries to Benin. Its internal political development from that time involved complex power struggles between the party of the ruler, the oba, and the nobles. In theory there existed a complex balance between different interest groups, but that balance shifted in different generations. Interestingly, it seems that the central authorities were so well aware of the dangers of allowing power to pass to locally based kin groups that much ingenuity was exerted in creating structures that ensured that commoners' kin groups did not develop and that politically ambitious individuals had to seek advancement by moving to the capital of Benin and could not create power bases in their home areas. In this the social structure of Benin was almost the reverse of the adjacent Yoruba areas.

To the east of the city of Benin lies the Niger delta, one of the greatest mangrove swamps in the world, an area without land for farming or any resources needed for the development of large states (until the discovery and exploitation of petroleum in the mid-20th century). In the 18th and 19th centuries, in that area and farther east at the mouth of the Cross River, there developed small, independent trading settlements. At first most were villages exchanging fish for agricultural produce; later, wherever deepwater anchorages existed—suitable for European ships and close to rivers giving good access to the interior— these settlements became large trading centres interested in exerting commercial control over the palm-oil-rich and slave-rich hinterlands.

Throughout much of the Guinea Coast the king or chief was the keystone of the political system because, although his actual powers varied enormously, his ritual relation to his predecessors and, usually, the gods provided the ideological framework for that system. In some cases he was the only appropriate intercessor with his deceased ancestors who were believed to exercise a controlling influence over group affairs. In other cases he was transformed, by his installation rites, into a person so sacred that all his actions had to be circumscribed lest, by breaking taboos, he brought disaster on his people.

Political structure of the kingdoms In Oyo, one of the best-described Yoruba kingdoms, the king, at the culmination of his installation rituals, ate the heart of his predecessor and was transformed into a personification of his ancestors. Thereafter, on his only public appearances, at rituals held three times a year, he appeared veiled, his face hidden by a beaded fringe. Those who formally represented him in judicial, religious, military, and administrative capacities were slave eunuchs, chosen because, having neither kin nor affines, they were presumed to have no interests to serve but their master's. Although secluded, it appears that the king was involved in important political maneuverings, playing one group of hereditary chiefs off against a second and trying to avoid the great danger that would ensue if both groups were to unite against him.

Such political structures can be described as if they were frictionless systems of checks and balances persisting un-

altered for generations, but modern research suggests that these structures were changed in detail whenever the balance of political power shifted. Points of particular struggle were the rules for choosing the successor to king or chief. In polygynous societies even a rule of inheritance by the eldest son does not necessarily indicate the true heir as there is room for dispute over the status of the mother. Any rule that widened the choice—*e.g.,* to any member of a lineage—gave increased powers to the selectors. Furthermore, military success could bring great problems, for if new territories were conquered there might be great competition between king and barons over claims to control the offices essential for the administration of these areas.

Variety of chiefdoms These structures, based on similar beliefs in the ritual powers of chiefs, are to be found in many chiefdoms of the Guinea Coast, even very small ones. Nevertheless, there were some political units that might be called essentially secular. Mende chiefs, for example, were explicitly leaders whose rule was based on military prowess. In Niger delta and Efik towns senior priests had ritual headship but lacked any political importance, for power was held by rich traders. Leadership in many Igbo villages often lay de facto with wealthy men who were members of influential societies; there were few formal political offices, and decisions were reached through public discussions at village meetings. It is not coincidental that even in modern times attitudes to social hierarchy are markedly different between the Yoruba and Igbo and that the latter adopted with particular enthusiasm the patterns of "democratic" politics.

Kin groups and other associations. Kinship ties are almost invariably of great significance in all traditional African societies, and the Guinea Coast is no exception. For the individual, ties through both the father and the mother are significant, but for inheritance and for political and legal purposes kin groups were commonly organized by singling out a particular line of descent. Such kin groups still exist in this area, but they have lost much of their former importance; in the past, however, they were of great significance. Their bases might be patrilineal or matrilineal, or both these lines of descent might be recognized simultaneously in different contexts. Most Yoruba kin groups are patrilineal, the Asante groups are matrilineal, and along the Cross River there exist a number of variations of "double unilineal" descent, a system in which each individual belongs to both a patrilineage and a matrilineage that share areas of authority. Kin structures such as clans were usually of great significance in the administration of groups even in large and complex kingdoms although, as in the case of the Benin kingdom, there were exceptions. Even in matrilineal societies almost all important offices were held by men but, because women in such groups determined the group affiliation of their children and were of great formal significance in establishing a man's rights (as he claimed political office through his mother), women commonly attained a freedom of action and a degree of public significance that was difficult for them to acquire in patrilineal kin groups.

The rights of women in marriage varied considerably from group to group, but in many Guinea Coast societies, even patrilineal ones, it would generally be a mistake to regard women as having been particularly downtrodden in the past. Even when this superficially appears to have been the case, careful research reveals that, as very active economic partners of their farmer husbands, wives might exercise much influence over the allocation of crops and even of patrilineally inherited land. Among the double unilineal Mbembe of the Cross River, although the land a family used was normally given to the husband by his patrilineal kin, the wife's labour was clearly recognized as entitling her to part of the crops. The husband had an absolute obligation to retain enough of the crops to provide her and her children with food, and his wife was regarded as justified in divorcing him if he were irresponsible in his use of any money he had gained through their sale. The specific duties of husbands and wives in relation to different types of plots were detailed with great care, and a wife was entitled both to an area of her own for raising cash crops and to her husband's labour on it for

Age-sets

Secret
societies

certain tasks. Among the Yoruba the husbands and their sons did almost all the farm work, and the women were responsible for marketing. Today sons move to the towns and husbands may employ labourers, but the old pattern remains and women continue to sell the produce. In an era when commercial marketing is much more important than formerly, many wives derive greater profit from the family's activities than do their husbands. Even in the modern urban environment the tradition of financial independence between husband and wife continues, but there the balance of advantage between husband and wife is less clear-cut.

In most tribal societies age is an important basis for group formation, and in some there exist "age-sets"—compulsory groupings of individuals of roughly similar age who advance through life together. No society in western Africa attached the same political significance to age as did some East African societies, where age stratified the male population into groups with markedly different levels of rights and authority. In the Guinea Coast, age groups tended to be more important in societies with weakly developed formal political structures; Igbo groups, for example, attached considerable importance to status given by age-set membership. In the Benin kingdom groups structured by age were, similarly to most other aspects of life, subjected to manipulation from the centre. If a man remained in his village his age-status was determined solely by his birth; if he went to Benin City and served in one of the so-called palace societies he might return home after a period and be entitled to promotion to an age-set beyond his years. This was a distinct inducement to go to work at the capital, and, since ultimately elders held sway in the village, the effect was probably that the most vigorous and, therefore, leading elders were relatively young men who had been influenced by the Benin City "establishment." Quite apart from the political signficance of age-sets, however, they might provide very significant personal ties for individuals who existed independently of any kin group organization to which they were attached. Among the Mbembe of the Cross River, for example, women as well as men derived great personal support from their age-mates. While kin-group membership established formal rights and obligations both between members and as collectivities in relation to the rest of society, age-sets provided friends who supported the individual through thick and thin. Age-mates were the witnesses called in when husbands and wives quarreled; age-mates would continue to find money to help the chronically sick even after kinsfolk gave up trying to aid; and in cases in which it was believed that a sick person was the victim of a sorcerer, always believed to be a kinsman, it was the age-mates who as a body would demand that he desist. The links between age-mates there, and elsewhere where they united individuals in different kin groups, did, however, have a political aspect, for they were of great value when kin-group elders met to deal with intergroup arguments; often the elders were age-mates and had the closest personal ties with one another.

One of the most characteristic of Guinea Coast institutions, especially in areas in which central government was weakly developed, was the so-called secret society. Such societies had a significance similar to that of age-sets because they cut across kin-group lines and united people in different settlements or of different political groups. Moreover, the fact that membership was often graded and the higher grades were open to those who could pay the fees meant that in societies where new wealth from trade became important it was often through these societies that wealthy men (few were open to women) achieved political influence to which they might not otherwise have had access. In two major areas—in Sierra Leone and Liberia, and in the area east of the Niger delta—these associations achieved such power that they were crucial to the precolonial systems of law and order. Among the tribes in the former area, there was a women's society, Sande, but Poro, for men, was the major organization responsible for punishing such serious offenses as incest and homicide. There were local Poro councils composed of members of the highest grade, and a chief's authority often rested on his Poro rank. Poro spread among the Gola, Kpelle,

and Mano of Liberia and the Mende of Sierra Leone. Sometimes its members forged links between autonomous chiefdoms, and in 1898 the Mende Poro even organized a general uprising to try to oppose British expansion into Sierra Leone.

The most interesting example of the politically powerful secret society, however, was probably that of Ekpe in 19th-century Calabar, the Efik capital at the mouth of the Cross River. There the Ekpe society was the main instrument of the governing oligarchy of wealthy traders. There was no strong central government to ensure that traders honoured their commitments either to one another or to European traders, but the threat of Ekpe action usually ensured compliance. The power of Ekpe is credited with having made Calabar society one of the most stratified on the Guinea Coast. Its membership was reserved almost exclusively for freemen, and its power was used to subordinate the large slave population. In the neighbouring delta area many able slaves who escaped exportation were eventually incorporated into local groups and became almost indistinguishable from the local population. In Calabar, perhaps because there was more agricultural land available, unexported slaves were kept as serfs. A few became prosperous and had slaves of their own (no one who had any pretensions did his own manual work). Ekpe members, however, banded together to maintain the free-slave distinction. Not surprisingly perhaps, Calabar was a place of bitter friction and saw slave uprisings in the middle of the century. In general, secret societies were institutions for translating slight advantages of wealth into political influence, and wherever they occurred they indicated the existence of a measure of social stratification greater than that which commonly distinguished the successful elder from his junior kinsmen. The idea that small-scale tribal societies were essentially egalitarian has become much less tenable with recent research. It is recognized that, even in apparently unstratified societies, successful men usually depended for their position on their ability to control the labour of junior male kin and wives. Often they used their positions to increase their control over both at once, for by marrying polygynously while keeping young men wifeless they ensured an excellent labour supply for themselves. This was crucial because, until the mid-20th century, the densities of population were so low that land was not really scarce; what was scarce was the labour with which to work it. It is significant, for example, that even among the apparently unstratified societies of the Cross River, the Yako and the Mbembe, one of the most important of their secret societies was that used to punish young men who failed to work adequately for their fathers. Land was freely available, and for various reasons it was difficult to prevent young men from marrying and setting up their own households; the main sanction the elders could use was to call on members of this society to beat any recalcitrant junior who showed his face in the main settlement.

Stratification was most obvious among wealthy and centralized states. However, because wealthy men were always polygynous and usually had many offspring, the wealth of one generation was commonly dispersed in the next, so that class formation was limited—the hereditary basis of high status was lacking.

In the 19th century new forms of stratification emerged in Sierra Leone and Liberia when freed slaves educated in North America were settled in these areas to become the "Creoles," shopkeepers and white-collar workers—an elite vis-à-vis the natives. Some Sierra Leonians moved to other British West African possessions on the coast, where they joined with tiny indigenous elites drawn from wealthy, educated coastal families to form with them a new bureaucratic class. In the 20th century access to good education has done much to confer hereditary advantage on the children of the elite.

Belief systems. There are, at least in outline, similarities between the various belief systems on the Guinea Coast. Most systems contain these features: belief in a withdrawn high god; belief in lesser gods that are useful because easily manipulated; concern with the dead, usually but not necessarily ancestors, who are thought to exercise influence over the groups to which they belonged

Freed
slaves
from
North
America

in life; and belief in witches and sorcerers, whose existence explains undeserved misfortune. Finally, there is common acknowledgment of the power of diviners who can determine the cause of a particular misfortune. Beliefs as to what constitutes the basis of diviners' powers vary widely, but there is such a pragmatic attitude that what matters is the apparent success of the divination, not its conceptual foundation. Diviners in the past traveled widely between societies. They often advertized the power of distant cults, and sometimes priests were brought long distances to establish new local shrines. In this way famous cults spread widely, and this fact may help to account for the existence of broadly similar beliefs between societies that have had apparently rather little contact with one another. In general, however, these religious beliefs are broadly compatible with the type of society in which they are found, so that there tended to be complex pantheons of gods in hierarchical and stratified kingdoms such as Dahomey, but small-scale, stateless societies lacked that kind of complexity among their deities.

These beliefs accounted not only for misfortune but also for individual success. There was a widespread belief that individuals, in an existence before birth, had to choose whether their earthly lives should be fortunate or unlucky, and consistent lack of success might be ascribed to wrong choices—so-called prenatal fate. In some societies particularly fortunate individuals were presumed to have established a relationship with a luck-bestowing supernatural being—for example, the water spirit of the Niger delta. In other societies undue prosperity was suspect and might be ascribed to membership in a sorcerers' society, which was believed to give wealth to its initiates in return for a sinister fee: the life of a relative. In such societies the implication was that the individual could get ahead only at the expense of his kin.

Throughout the Guinea Coast the influence of Christian missionaries has been prolonged and considerable, and in many areas there are flourishing and orthodox locally run churches. This does not mean that all traditional religious explanations of the events in a human life have disappeared. Sometimes they continue to constitute a kind of fall-back position, so that local diviners may be consulted in cases of illness where modern medicine seems powerless. Sometimes they are blended into complex new sects with Christian and Muslim elements, as in the Yoruba-centred Church of the Cherubim and Seraphim. This has spread into distant areas because it combines many of the characteristics of the churches—comparable buildings and forms of worship—with a traditional concern for healing and the explanation of untoward events. In general, however, Guinea Coast cultures have come under significant Christian influence, and this distinguishes them from the northern hinterland that is predominantly Muslim. Insofar as Islām has been spread by the sword, it is not a matter of chance that the old forest zone, inimical to cavalry, formed a barrier beyond which this faith has been slow to penetrate. European colonialism subsequently protected the southern peoples from further forcible conversion by jihad. Thus the natural vegetation zones described at the beginning of this section have continued, for complex reasons, to be distinct cultural zones, particularly because education has depended very much on the activities of Christian missions, so that until recently the new educated elite of much of western Africa has been drawn predominantly from the southern Guinea Coast area. This elite has staffed the state bureaucracies and the modern commercial enterprises, giving southerners many advantages but also increasing the political problem of regional jealousy.

Modern relationships. When the present-day states of the Guinea Coast are considered in the context of the modern world, it is important to be aware of the ethnic diversity within nations whose boundaries have been dictated by colonial powers that paid scant regard to indigenous ethnic divisions. Despite the many changes that have taken place, old loyalties to these divisions sometimes remain strong. Ethnic patriotism may lead to a reassertion by the educated elite of the value of their particular local culture.

Ethnic divisions may, however, be less ultimately divisive than the new patterns of economic stratification. There are now vast differences in income and power between the rural population and the urban poor on the one hand and the politically and economically successful minority on the other. This is particularly noticeable in Nigeria, where a devastating war was followed by massive inflation, partly related to petroleum development, and where new laws have allowed powerful men to expropriate the land of peasant farmers.

Modernization has brought political and economic problems, but the Guinea Coast continues to be an area rich in cultural tradition. The region has produced not only scholars of high quality in many academic fields but also many imaginative writers, the best of whom are among the outstanding contemporary novelists and playwrights writing in French and English. History

A reasonable body of sources for the writing of western African history begins to be available from about AD 1000. Three centuries earlier, the Arabs had completed their conquest of Africa north of the Sahara and so came into possession of the northern termini of trade routes reaching across the desert to western Africa. The lively school of geographers and historians that flourished in the Muslim world from about the 9th to the 14th century thus secured access to growing amounts of information about what they called the *bilād as-sūdān*, the territory of the black peoples south of the Sahara.

MUSLIMS IN WESTERN AFRICA

This information has its limitations. The Muslim writers, contemptuous of non-Islāmic societies, passed on little of what they must have known about the organization of pagan black societies and tended to concentrate on and condemn what struck them as their more monstrous aberrations. Conversely, they doubtless exaggerated the importance of the Islāmization that entered western Africa with the Muslim traders crossing the Sahara. The earliest firsthand account of western Africa is probably that of the world traveler Ibn Baṭṭūṭah, who visited the western Sudan in 1352–53. Finally, the North African merchants did not penetrate into western Africa beyond the urban centres of trade and government that existed or came to develop on the northern fringes of the cultivable savannas fronting the Sahara. Their *bilād as-sūdān* was in fact only the northern marches.

Nevertheless, the picture of western Africa given in the early Muslim writings is of major interest. It is apparent that, right from the beginnings of Arab contact, the organization of the more northerly western African peoples was not solely tribal. They had considerable towns and cities that were supported by a developed agriculture. They had organized networks of markets and trade and a developed system of monarchical government. Kings, whose claim to power was based on descent from the mythical divine founding ancestors of their ethnic groups, taxed trade and levied tribute on the agricultural villages through their possession of bodies of retainers who provided them both with military force and with a hierarchy of officials.

It seems likely that there was an increase in the volume of trans-Saharan trade following the organization of North Africa under Muslim dynasties and that this growth of international trade with western Africa stimulated the growth there of internal trade, urbanization, and monarchical government. Certainly the control of trade, towns, and government in western Africa became increasingly Islāmic in form. But it is quite clear that the foundations for the economic and political development of the western Sudan were in existence before the time of contact with Muslim traders or authors. Early Muslim interest was concentrated on two major western African kingdoms: Kanem, in the east, north of Lake Chad; and Ghana, in the extreme west, on the borders of modern Mauritania and Mali. The Muslim sources, which are broadly confirmed by local tradition, indicate that the kingdom of Kanem was being formed during the 9th and 10th centuries through an interaction between Saharan nomads

The kingdoms of Kanem and Ghana

and agricultural village communities. But ancient Ghana (not to be confused with its modern namesake, considerably farther to the south and east) had already reached levels of organization that presuppose several centuries of continuing development.

The earliest extant Arabic reference to a kingdom of Ghana dates from the early 9th century. In the middle of the 11th century, the Córdoban geographer Abū U'bayd al-Bakri described its capital, court, and trade in some detail. The capital was made up of two towns, a stone-built town inhabited by the Muslim traders and a mud-built one of the local Mande in which the king had his walled palace. Their centres were six miles apart, and the whole of the intervening country was more or less built up. The considerable population was supported by the produce of surrounding farms, which were watered from wells. The court displayed many signs of wealth and power, and the king had under him a considerable number of satellite rulers. A principal part of his revenue was derived from regular taxes on trade. The mainstay of this trade was the exchange of gold, which Ghana's own merchants brought from lands to the south, for salt, which the northern traders brought in from salt deposits in the Sahara.

Al-Bakri's description is broadly confirmed by archaeology. The region in which ancient Ghana was situated contains the ruins of a considerable number of stone-built towns that must have been supported by considerable agricultural and commercial activity; those at Koumbi Saleh are generally identified with the capital described by al-Bakri.

The relatively extensive Muslim interest in Ghana was undoubtedly due to its importance as a source of gold. Kanem seems to have been less important commercially; the main interest of the Muslim authors seems to have been in the quasi-divine status of its kings, which offended their Muslim principles. Other western African kingdoms undoubtedly existed at this time, but the Muslim sources record little of them beyond their names and approximate locations. Thus between Ghana and Kanem was Kawkaw, perhaps the nucleus of the later Songhai kingdom of Gao. Malel, to the south of Ghana, may similarly have been a prototype of the later Mande kingdom of Mali, which ultimately was to eclipse and absorb Ghana itself.

There are perhaps three possible—and not mutually exclusive—explanations for the origins and development of the kingdoms that Arab trade and scholarship had revealed

Other kingdoms

by about AD 1000. The first is that they were the result of the invasion of agricultural territory by pastoralists from the Sahara who belonged to the Hamitic-speaking Libyan Berber tribes who were the dominant stock of North Africa before its conquest by the Arabs.

This is the explanation often given in western Sudanese traditions and chronicles. From about the 15th century onward, many of these were preserved by local authors who wrote in Arabic and were Muslims, and who thus had some incentive to link the history of their peoples with that of North Africa and with the adjacent Middle East. It was also the explanation favoured by European historians of the later 19th and earlier 20th centuries when Europeans were themselves conquering and colonizing black Africa. There thus evolved the so-called "Hamitic hypothesis," by which it was generally supposed that any progress and development among agricultural blacks was the result of conquest or infiltration by pastoralists from northern or northeastern Africa. Specifically, it was supposed that many of the ideas and institutions of tribal monarchy had spread through Africa by diffusion from the ancient civilization of Egypt and the Nile valley.

There can be no doubt that over the centuries pastoralists from the Sahara have indeed advanced and conquered southward. But not all of these were Libyan Berbers or Hamites; some, such as the dynasts of Kanem, were black African in language and culture. Nor is it easy to understand how mobile desert pastoral tribes could be effective transmitters of ideas and institutions from the settled civilization of the Nile valley to other agricultural lands in western Africa. It would seem more probable that conquering pastoralists who did succeed in establishing new kingdoms and dynasties in western Africa should do so by taking over existing monarchies, perhaps city-states or even "village-states," and amalgamating these into larger units. Some early western African traditions can certainly be interpreted in this sense.

This leads to the second explanation for the origins and development of monarchical statehood among the western African tribes. There is archaeological evidence for the evolution of a cattle-herding and agricultural economy among a mixed population of Libyan Berber and black agricultural peoples in the Sahara by at least 4000 BC—*i.e.,* more or less contemporary with similar developments in the Nile valley. The desiccation of the Sahara and the evolution of its present desert between about 8000 and 2000

Formation
of black
African
monarchies

BC must have occasioned an outflowing of population in which the blacks concentrated in the savannas to the south of it. There, in favourable riverine or lacustrine environments, it seems reasonable to suppose that the same desire to avoid conflicts over land and water rights and to control and exploit agricultural surpluses, which had led in the exceptionally fertile but extremely constricted environment of the Nile valley to the dramatic kingship and civilization of the pharaohs, should have occasioned the evolution of similar if less spectacular monarchies.

It should be noted, however, that the major western African monarchies known to the Arabs by about AD 1000 were situated not in the well-watered lands along the Sénégal and Niger valleys nor around Lake Chad but north of these, in the less favoured agricultural territory between them and the southern edges of the Sahara. This suggests that a third factor in the evolution of these northern monarchies was the influence of long-distance trade. The western African kingdoms had their own resources of iron, which in some cases were being worked by about 500 BC, but they imported other metals, notably copper, together with horses, luxury manufactures, and—above all—salt, a vital commodity that was scarce in all of western Africa except the coastlands. In exchange they could offer gold, ivory, certain agricultural commodities, and slaves.

The exchange across the Sahara of such commodities probably goes back to times before the establishment of the modern desert. The emergence of the desert did not lead to the cessation of the trade but meant that its surviving pastoralists were encouraged to organize regular trans-Saharan expeditions for trade and plunder. It is known from Herodotus and other classical authors and from surviving rock engravings in the desert that horse-drawn chariots were in use in the Sahara by about 500 BC. Chariots would have been used for short raids rather than for trans-Saharan trade. But the fact that the engravings are deployed along two principal lines, from the Fezzan and southern Morocco toward the upper Niger and Sénégal rivers, suggests a North African interest in the alluvial gold of these rivers. This could well have occasioned the 6th-century Carthaginian expedition led by Hanno to explore the possibility of direct sea trade with western Africa along the Atlantic coast. Despite this expedition, the Carthaginians do not seem to have been capable of opening up a regular sea trade with western Africa. The

Trans-
Saharan
trade

links with western Africa remained firmly in the hands of the Saharan tribes, although, at about the beginning of the Christian era, camels and other pack animals came into use to supplant the horse-drawn vehicles.

The profits to be obtained by distributing Saharan and Mediterranean produce in western Africa, and by controlling the collection and export of the western African commodities that were exchanged for them, must have been a powerful factor in encouraging the kings of communities on the southern fringes of the Sahara to extend their rule by conquest over adjacent similar communities. Control over more extensive territories meant that by tribute and taxation they could acquire greater stocks of goods for exchange with North Africa and the Sahara and more clients and slaves to extend their power at the expense of their neighbours. Some of their increased human power could be mounted on horses, obtained from the Saharan trade, to increase the mobility and power of their armed forces over the open savannas. It is tolerably certain that the power of the kings of ancient Ghana, controlling the export of gold from the Sénégal and Niger valleys, was built up in this way.

THE STATES OF THE SUDAN

The early kingdoms and empires of the western Sudan. In the 10th century the kings of Ghana extended their sway over the Sanhājah, the congeries of Berber nomadic tribes living around Audaghost, just north of their kingdom, who supplied them with salt and North African goods.

This move must have upset the economic balance between agricultural Ghana and the pastoral Sanhājah, and ultimately it provoked a reaction. Like the North African Berbers, the Sanhājah tribes were already to some extent Islāmized, and they shortly found in a militant, puritanical version of Islām the means to eliminate their tribal differences and to unite in the movement known to history as the Almoravids. In the middle of the 11th century they began to expand into the productive lands on either side of the western Sahara, and it would seem that later in the century Ghana became dominated by them.

One important result of this domination, following as it did upon some centuries of trading contact by Muslims, was that the ruling and merchant classes of the western Sudan became converted to Islām—though in the case of the rulers the conversion was for many centuries not wholehearted. The justification for a king's claim to enforce his rule over his subjects, who remained pagan, was his descent from the original ancestor who had first settled the land and, by accommodation with its deities and spirits, had developed and controlled it for agriculture. If he were not to be rejected and replaced as king by a rival member of its royal family, he had to continue to observe the ancestral and land cult rites in which he was the principal figure.

However, the depredations of the Almoravids' herds and their internecine quarrels must have undermined the prosperity of agriculture in a marginal environment and would have accelerated the decay of Ghana. More southerly Mande groups, many of which had formed satellite kingdoms of the Ghana empire, began to act independently and to compete among themselves for primacy. Eventually

The rise
of Mali

in about 1235, in the time of a king called Sundiata, the Keita kings of Mali, in the well-watered and gold-bearing lands of the uppermost Niger valley, gained ascendancy and incorporated what was left of ancient Ghana into their own considerably more extensive empire.

The Keita clan seem originally to have been traders from lower down the Niger, and the strategy of their empire was to extend their power down river to the Niger Bend and to its trading cities of Timbuktu and Gao, which lay at the foot of the shortest trans-Saharan routes. The initial success of the Almoravids and their subsequent rapid decline had upset the stability of the more westerly caravan roads leading to Ghana, while in the 13th century Ifrīqiyah (Tunisia and eastern Algeria) and Egypt provided more stable bases for trans-Saharan trade than did Morocco. The Niger River provided a natural means of communication from Mali and its goldfields to Timbuktu and to Gao and also provided Mali's merchants with the possibility of opening up trade elsewhere in black western Africa. By the 14th century, Mande merchants, the Dyula (Dioula), were trading as far east as the city-states of the Hausa, between Lake Chad and the Niger. By about the same time they had also begun to develop a new trade route southeastward from Jenne (modern Djenné, Mali), on a southerly tributary of the Niger, toward goldfields that were being opened up along the Black Volta and further south still, in what is now modern Ghana.

These Mande merchants were Muslims, and their activities led to a considerable expansion of Islām among the trading classes of western Africa and, with the qualification mentioned earlier, also among its kings. Thus the first conversions of Hausa monarchs seem to date from the 14th or 15th centuries. The Mali kings themselves valued Islām for the commercial and diplomatic advantages it gave them, and some of them, of whom the best known is Mansa Mūsā (1307–32), made notable pilgrimages to Mecca via Egypt. As may be seen from Ibn Baṭṭuṭah's account of his travels in 1352–53, the essentially pagan society of the western Sudan became open to a considerable degree of Islāmic influence, and literacy and even scholarship became firmly established in its major cities.

The success of the Mali empire depended, however, on its rulers maintaining firm control of the Niger waterway. This in its turn depended on their maintaining control over a non-Mande people, the Songhai, who monopolized the fishing and canoe transport of the middle Niger. The Songhai had an independent monarchical tradition of their own, and Mande control of their capital, Gao, proved somewhat fitful. During the 15th century it was lost altogether, and eventually a Songhai king arose, Sonni 'Alī (1464–92), who, appealing to traditional Songhai pagan-

ism against the Islāmic universalism of the Mande system, destroyed the Mali empire by ceaseless military campaigning and erected in its place a new empire ruled from Gao. But if this empire were to be profitable and strong, the Songhai needed the Mande as much as the Mande had needed the Songhai. After Sonni 'Ali's death, power passed to one of his former generals, al-Ḥājj Muḥammad Askia (1493–1528), who was both a Mande and a Muslim, and thereafter there was a continual struggle for power between the two groups.

The Songhai empire was never strong in the west, where a number of Mande kingdoms remained in the tradition of Ghana and Mali, but was more effective to the east. There the kingdom of Kanem, whose kings had become Islāmized in the 11th century, had declined during the 14th and 15th centuries following quarrels among its aristocracy when it was subject to pressure from new nomad invasions. Eventually, however, the Kanem kings reestablished their state in the former province of Bornu in the southwest, close by the Hausa kingdoms. But in the 16th century, Songhai was the most important external influence over the latter, which began to grow in power and importance. South of the Niger Bend the kingdoms of the Mossi-Dagomba peoples were emerging, founded by bands of cavaliers who may have been in some way connected with the ruling families to the northeast.

Songhai was strong enough to extend its sway northward across the Sahara to as far as the salt mines of Taghaza, close to the Moroccan borders. This upset the balance of trans-Saharan trade, as Ghana's attempt to control the Ṣanhājah had done, and in 1591 finally provoked effective retaliation from the Sa'di dynasty of Morocco. An expeditionary force of some 4,000 soldiers was sent across the Sahara and took the important cities of Gao, Timbuktu, and Jenne. The Moroccans had firearms, but their success against the much larger numbers of the Songhai army was also facilitated by the internal divisions of the Songhai state. For a time the profits of this enterprise were considerable, but the Moroccans were not strong enough to control the network of trade routes within western Africa that brought gold and other produce to the Niger cities. Ultimately the main gainers from their conquest were the Saharan tribes, essentially Berber in origin (such as the Tuareg) but now increasingly Muslim and even Arabized, who finally levied tribute on the descendants of the Moroccan soldiers who formed the military caste (Arma) of Gao, Timbuktu, and Jenne.

Firearms also came to the central Sudan about the same time through the trading relations that existed between Bornu and the Ottoman Turks in North Africa. Together with Muslim cavalry, they enabled Idris Alawma of Bornu (end of 16th century) to impose a Muslim bureaucracy on his pagan subjects and to reconquer Kanem. This revival of the Kanem-Bornu dynasty, however, was relatively short-lived. By the 18th century it was the much smaller Hausa kingdoms, especially Kano and Katsina—which had learned much from Mande commercial and industrial experience and had developed a trading network to the south to rival that of the Mande themselves—that took the leading role in western Africa's external trade with North Africa across the Sahara.

The wider influence of the Sudanic kingdoms. The development of such major Sudanic kingdoms and empires as Ghana, Mali, Songhai, the Hausa states, and Kanem-Bornu along the southern fringes of the Sahara had a number of important consequences for the history of western Africa as a whole. For example, it provided the background for the expansion of the Fulani, the only pastoral western African people (also variously known as Fulbe, Fula, Fellata, and Peul).

The fact that, uniquely in western Africa, the Fulani are pastoralists and that physically they have some non-Negroid traits has led to suggestions that they were originally a Saharan people. The Fulani language, however, is classified as part of the Niger-Congo family of languages spoken by black Africans, and the earliest historical documentation reports that the Fulani were living in the westernmost Sudan close to ancient Ghana. The development of this organized kingdom thrust pastoral peoples

outward, and the ancestors of the modern Fulani seem to have chosen to settle to the southwest, toward the middle Sénégal valley. But there another settled, and (from the 11th century) an Islāmized, black kingdom evolved, that of Tekrur. Some Fulani participated in this kingdom and became Tukulor (Toucouleur)—the Tukulor and Fulani languages being practically identical. Some, however, chose not to accept the settled way of life and, to preserve their traditional pastoral and religious customs, migrated eastward over the savanna grasslands. Grazing land was available between the agricultural villages, and the growing towns provided the Fulani with markets where they could exchange their pastoral produce for agricultural and manufactured goods. Eventually some Fulani settled in these towns, no doubt initially as trading agents for their fellows in the countryside, where the bulk of the Fulani continued to live under their own leaders, aloof from the social and political life of the cultivators, though increasingly paying rent for their grazing and rendering military services to the settled authorities.

The
Fulani
diaspora

In this way, by the 15th century, large numbers of Fulani had settled in the Fouta Djallon and in and around Macina, the inland delta country of the Niger upstream of Timbuktu, and they were beginning to appear as far east as Hausaland, where today many millions of their descendants live. By the 16th century the Fulani were appearing in Bornu, and by the 18th century large numbers of them were settling in the grassy uplands of the Cameroons. Although the bulk of the Fulani remained animists, gradually significant numbers of them became Muslims and indeed provided some of the leaders of Islām in western Africa.

The growth of organized statehood in the western African savannas also had important consequences for more southerly lands and peoples. Unsuccessful contestants for power in the major savanna states sometimes moved off toward the south. Traders from these states, especially from Mali and, later, from the Hausa kingdoms, also settled in the south as their trading networks developed, and they often had important political, as well as economic, influences on the tribal groups with whom they came to live. The consequences of these two kinds of movement, which were sometimes interlinked, can best be considered in two sections—firstly, those deriving from developments originating in the Mande sphere in the western savannas, and secondly, those deriving from the Hausa-Bornu region in the east.

Southerly
move-
ments

In the west one notable emigration was that of the Susu, a Mande group that had lost out to the Keita in the 13th-century struggle for the inheritance of ancient Ghana. This emigration created a wedge of Mande-speaking people close to the Atlantic in the modern Republic of Guinea and in northern Sierra Leone among peoples who had not advanced politically beyond the village level. With the subsequent growth of Mali's power, other smaller groups—sometimes traders, sometimes conquerors, often both—also infiltrated these West Atlantic coastlands. They began to organize their people into petty kingdoms that tended to owe a nominal allegiance to Mali. Major incentives for these migratory movements seem to have been the desire to gain access to coastal supplies of salt and, from the 15th century onward, to the foreign merchandise brought by European sea traders.

In the 16th century the West Atlantic coastlands were invaded by yet another Mande group, the Mane, who advanced westward parallel to the coast from Liberia onward. These were military bands that systematically attacked and overcame the villages of each tribal group they came across. Some of them would stay behind to organize these conquests into small kingdoms, while others, reinforced by auxiliaries recruited from among their victims, would proceed farther west to repeat the pattern. Their advance was halted only when they came up against the Susu. South and east of the Susu, however, the West Atlantic social and ethnic patterns were considerably altered by the actions of the Mane. New Mande-speaking groups emerged, such as the Mende and Loko, while some West Atlantic peoples who retained their original language, such as the Temne, accepted a new aristocracy of Mane provenance.

(Left margin notes:)

The extent
of the
Songhai
empire

The Mane advance into the West Atlantic coastlands from the east may have been connected with the growth of Mande influence in the Ivory Coast and in modern Ghana. This was commercial in origin; Dyula merchants developed trade routes in search of gold, slaves, and kola nuts, in exchange for which they offered salt, cloth, and other Sudanic or North African goods. It is known that by 1500 the Dyula were trading as far south as the coast of modern Ghana, and their first contact with the Akan peoples who populate almost all the southern half of this territory was probably one or two centuries earlier than this.

This development of trade by the Dyula in modern Ghana and in the adjacent Ivory Coast had important political consequences, and sometimes military implications as well. Ambitious Akan chiefs began to develop and expand their political power to secure the maximum profit from the exploitation of the resources of as much territory and as many people as possible. On the northern fringes of the forest, astride the routes along which gold and kola nuts were brought for exchange with the Dyula, important new kingdoms emerged such as Bono and Banda, both of which were probably in existence by about 1400. As the economic value of gold and kola became appreciated, the forest to the south of these states—which had hitherto been little inhabited because it was less favourable for agriculture than were the savannas—became more thickly populated, and the same principles of political and military mobilization began to be applied there. Village communities became tributaries of ruling groups, with some of their members becoming the clients and slaves needed for the support of the royal households, armies, and trading enterprises. By 1500 most of the Akan territory seems to have been organized in this way and, as trade increased, so the political units—initially very small—tended to increase in size.

Sometimes these political changes were not to the advantage of the Dyula, who employed Mande warriors to guard their caravans and, if necessary, could call in larger contingents from the Sudanic kingdoms. Tensions between the Dyula and the increasingly powerful animist monarchy of Banda erupted in the 17th century into a civil war that destroyed the kingdom and led its Dyula merchants to establish a new trading base of their own farther to the west at Bonduku (Bondoukou). In the following centuries there were at least two major examples of the Dyula taking

Increasing power of Akan

political authority for themselves at strategic points on the trade routes running through the eastern Ivory Coast.

But the most interesting Mande political initiative along the trade routes south of Jenne was the creation in the early 17th century, just north of the Akan lands, of the new Dyula state of Gonja. This seems to have been inspired by a general worsening of the competitive position of the Mande traders, and it was occasioned by three factors: (1) the near monopoly in the control of the export of forest produce achieved by the Akan kingdom of Bono; (2) the rise to power farther north of the Dagomba kingdom, which controlled local salt pans; and (3) the arrival in the region in about 1500 of rival long-distance traders from Hausaland. The Dyula seem to have tried to combat these developments by erecting a major kingdom of their own in Gonja—the territory that the northern traders had to cross to reach the Akan forestlands. But much of Gonja was barren, and its kings lacked the resource base to withstand the growth of Akan power.

Rather less is known about the nature of Sudanic influences in the more easterly zone south of Hausaland and of Bornu. However, it has already been suggested that Dagomba (and a number of similar kingdoms in the Volta basin, including Mamprusi) and the Mossi kingdoms—such as Wagadugu (Ouagadougou) and Yatenga (or Wahiguya), north of Dagomba and closer to the Niger Bend—were founded by conquerors coming from the east. The structures of these kingdoms, which were extant into the beginning of the colonial era, seem to have been erected about the 15th century by relatively small bands of immigrants who eventually merged with the autochthonous Gur-speaking inhabitants of the Volta basin. Their success in conquering and organizing the Gur villages into kingdoms seems to have been due to their possession of cavalry, which subsequently remained a badge of royalty and of aristocracy.

Somewhat earlier, and farther to the east, astride the Niger and closer to Hausaland, similar kingdoms seem to have been developed through the same kind of process by invaders who may well have been ancestral to the Mossi–Dagomba state builders. Examples of these survived in Borgu into colonial times. An interesting corpus of legends—such as that of Kisra, a character derived from the Sāsānian conqueror of Egypt, Khosrow II, who is supposed to have migrated southwestward from the Nile valley founding various kingdoms—suggests that state-building

Principal kingdoms and peoples of western Africa, 17th–19th century.

invaders also proceeded south of Borgu and Hausaland through Nupe, Jukun, Igala, Yoruba, and Benin territory (all in modern Nigeria) to as far as southern Dahomey and to the southeasternmost tip of modern Ghana. Much of this territory, however, was subjugated in the 19th century by Muslim Fulani and Hausa, and the legends as they survive often have an Islāmic colouring, which makes it difficult to assess their historicity. It could well be that the traditions of the autochthonous pagans had become coloured by the folklore of incoming Muslim traders. But if the legends are really evidence of conquest, there can be no doubt that the conquered peoples had already achieved a high degree of cultural, economic, and—probably—political sophistication.

The archaeological evidence of the Nok culture shows that the inhabitants of central Nigeria engaged in agriculture and were using iron and other metals by about 500 BC. It is moreover generally accepted that the terracotta sculptures associated with Nok are precursors of the later court sculpture of southwestern Nigeria, in bronze or brass and stone as well as terra-cotta. The bronze or brass sculpture of Yoruba and of the kingdom of Benin is especially famous for its naturalism and for the high degree of metallurgical skill used to cast the figures by the lost-wax process.

Tradition asserts that the Yoruba town of Ife (Ile-Ife) was the centre from which this art, and the type of monarchy that supported it, spread to other parts of the region. Modern archaeologists have found nothing to contradict this and have moreover provided evidence for the existence in Yorubaland of a high degree of urbanization by at least the 11th century. Thus in southwestern Nigeria urban civilization seems at least contemporary with the same development in Hausaland and in Kanem–Bornu, the point of departure for Kisra-type conquerors. The probability, therefore, is that if the Kisra and similar legends are evidence of conquering cavaliers, they were— like the Saharan invaders in the Sudan—exploiting rather than creating urban civilizations, though no doubt they may have welded smaller units into larger kingdoms.

It should be pointed out that the territory southwest of Hausaland toward Dahomey is often open country suited to the deployment of cavalry. The effectiveness of cavalry decreased southeastward toward the forest; in the Benin kingdom, horses were little more than residual symbols of monarchical and aristocratic power. Still farther east, in the forest on the other side of the Niger, where there are no traditions of invasion or of developed monarchical government, the archaeological finds at Igbo Ukwu revealed that ancestors of the modern Igbo (Ibo) had, as early as the 9th century, a sophisticated society with surpluses of wealth supporting considerable craft specialization, including a highly developed bronze art with a distinctive style of its own. Recent thinking suggests that the origins of the small, competitive city-states of the eastern Niger delta south of Igboland, with which Europeans were to develop flourishing commerce from the 17th century, may well be associated with earlier, purely indigenous trading activities of which very little is at present known.

On the available evidence, the establishment in eastern Guinea of the network of Hausa trade and trade routes in the form in which it has been known in modern times, essentially similar to the Mande system farther west, can hardly be dated earlier than about the 16th century. Yet the European traders arriving at Benin, in the Yoruba coastlands, and in the Niger delta, from the end of the 15th century, were able to secure regular supplies of goods, some of which (*e.g.,* cloth and beads) clearly originated in the hinterland and seem to have had an already extant market among the Akan peoples of southern Ghana. This presupposes appreciable indigenous commercial development in eastern Guinea before the emergence of the Hausa system.

THE BEGINNINGS OF EUROPEAN ACTIVITY

The arrival of European sea traders at the Guinea coastlands in the 15th century clearly marks a new epoch in their history and in the history of all of western Africa. The pioneers were the Portuguese, southwestern Europeans

with the necessary knowledge, experience, and national purpose to embark on the enterprise of developing oceanic trade routes with Africa and Asia. Their main goals were in Asia, but to reach Asia it was necessary to circumnavigate Africa, in the process of which they hoped, among other things, to make contact with Mali and to divert some of the trans-Saharan gold trade from Muslim North Africa to Christian Europe.

The colonization of the Cape Verde Islands, from the 1460s onward, provided bases for trade with the fringes of the Mali empire. The most momentous discovery in western Africa, however, came in 1471, when Portuguese captains first reached the coast of modern Ghana between the mouths of the Ankobra and Volta rivers. It was quickly appreciated that the Akan peoples of this coast had access to supplies of gold, which were plentiful by contemporary European standards, and that they were willing and organized to trade some of this gold for base metals, cloth, and other manufactures. The Portuguese called this coast Mina, "the mine," while in European languages generally it became known as the Gold Coast.

The wealth obtainable from trade with the Gold Coast was so important for the completion of the Portuguese design to establish regular commerce with Asia by circumnavigating Africa that the Portuguese crown quickly took steps to exclude foreign rivals from the western African trade and to bring it under its direct control. Portugal was not a naturally wealthy nation, however, and its overseas interests had become very widely extended by the beginning of the 16th century. The western African coastlands and their trade were only one element in a system that also embraced the Congo and Angola, Brazil, the East African littoral, and India and the East Indies. By and large it was the trade of the latter that was regarded as the major prize, and elsewhere activities tended to be restricted to those which might strengthen the prosperity of the overseas enterprise as a whole without unduly straining the limited resources, especially perhaps of labour, available for its control and exploitation.

The general strategy in western Africa—as elsewhere in the Portuguese trading empire—was to keep territorial and administrative commitments to the minimum necessary to develop and benefit Portuguese commercial activities that were already in existence. The main interest in western Africa was the gold trade of Mina, and it was there—and virtually there alone—that the Portuguese endeavoured to maintain a positive presence on the mainland. In 1482 they built the strong fort that they called São Jorge da Mina (the modern Elmina Castle) on the shores of the Gold Coast, on land leased from the local Akan, and in subsequent years this was supplemented by the construction of three additional forts, at Axim, Shama, and Accra. The purpose of these forts and their garrisons was to try to ensure that the local people sold their gold only to agents of the Portuguese crown. No other Europeans succeeded in establishing lasting footholds on the Gold Coast before the close of the 16th century, and the Portuguese purpose was largely achieved. The surviving records suggest that up to about 1550 the Portuguese were securing from the Gold Coast on average at least 12,400 ounces of gold each year, a sizable proportion of the production then available to Europe.

In exchange, the Gold Coast peoples needed to be supplied with commodities they desired, and this presented Portugal with a problem, as it was not a major manufacturing nation. The raw iron and copper, metal goods, cloth, and other items that were in demand on the Gold Coast had to be purchased elsewhere. Some of the cloth exported to the Gold Coast was in fact brought from Morocco (and may therefore have been in competition with a trade in cloth that had earlier reached the Akan from the north), and the requirements of their Gold Coast customers were a prime factor in leading the Portuguese to develop relations with the kingdom of Benin and the Niger delta, where further supplies of cloth, and also of beads and slaves that were in demand on the Gold Coast, could be obtained.

At first the Portuguese hoped to control the trade of Benin and surrounding areas by converting the kingdom,

or at least its court, to Christianity and turning it into a satellite protectorate of their empire. Although this kind of policy was initially successful elsewhere in Africa, notably in the Kongo (Bakongo) kingdom of northern Angola, the Benin monarchy was powerful enough to reject European pressures and infiltration. From about 1520 onward, the Portuguese were virtually excluded from Benin, and their trade with the Niger delta was conducted from São Tomé and from the other islands of the Gulf of Guinea that they had colonized. This trade was principally in slaves, from the Congo and Angola as well as from the delta, who were employed on plantations to grow tropical produce, sugar in particular, for the European market.

Apart from an abortive attempt to intercept the western trans-Saharan trade from a fort that was erected on the island of Arguin off the coast of Mauritania, the other principal Portuguese activity in western Africa was the trade with the coastlands of Upper Guinea that was conducted by the settlers on the Cape Verde Islands (which, together with Madeira, were also developed as plantation colonies employing African slave labour). The empire of Mali was in decline, but the Portuguese were not strong enough to control trade so far into the interior. What ultimately developed, on the creeks and islands of the coast from the Gambia to Sierra Leone, was a number of informal settlements where traders from the Cape Verde Islands did some trade with Mande merchants and with the local peoples. Gradually they married into the local trading and ruling families, and, escaping formal Portuguese control, became agents of the African commercial system who sought to secure the best terms they could from any visiting European trader irrespective of nationality.

It may be doubted whether this first period of European involvement with western Africa, from about 1450 to 1600, had much effect on the course of its history. The only Europeans consistently involved were the Portuguese, who were not strong outside the Gold Coast and who were really only interested in controlling some aspects of trade, and these only in a few selected areas of the coastlands where new opportunities had been opened up for a few members of the ruling and trading classes. Perhaps the main changes were that a few Africans acquired some acquaintance with Christianity and with elements of the Portuguese language—a pidgin variety of which became the lingua franca of coastal commerce for some centuries—and that western African farmers were introduced to some new crops and fruits, usually of tropical American provenance, which they quickly adopted if they were more productive than their established cultigens. For example, corn (maize) was more productive than millet and cassava more productive than yams under certain conditions.

The new era of maritime intercourse with the outside world was probably of marked significance only on the Gold Coast. There new avenues of wealth had been opened up for some of the Akan in trade at the coast. There too a new political problem had emerged of how to ensure regular and profitable commercial dealings with the Europeans, while at the same time preventing the coastal footholds, which the Europeans required as entrepôts, from subverting the sovereignty of the indigenous states. This was a very real problem, because the coastal kingdoms were small and divided among themselves in competition for the trade with the Europeans. Elmina certainly, and to some extent Axim also, did in fact develop independent jurisdictions over the mixed European, African, and mulatto trading communities that developed beneath the walls of the forts. Beyond these, the difficulty of maintaining large and effective forces of European soldiers in the tropics meant that the Portuguese could only exert power through African allies. The coastal people were thus able to maintain the principle that the land on which the forts were built was not ceded, but only leased. If the Portuguese lost their allies' confidence, the latter could refuse to supply or help defend the forts, or even destroy them altogether (as happened for the first time at Accra in the 1570s).

The rise of the Atlantic slave trade. The coastal peoples generally, and those of the Gold Coast in particular, were certainly prepared to welcome the merchants of other Eu-

ropean nations so as to decrease their dependence on the Portuguese. The first Europeans effectively to break into the Portuguese monopoly of sea trade with western Africa were the Dutch, who had been some of the principal distributors in northwestern Europe of the Asian, African, and American produce imported into Portugal and Spain. After the northern Netherlands had revolted against Spanish rule, however, and Philip II of Spain (who since 1580 had been king of Portugal also) had sought to punish the Dutch merchants by excluding them from the Iberian ports, they were stimulated to organize oceanic trading ventures of their own and from 1598 established on the Gold Coast the first Dutch trading posts in western Africa.

The principal targets for Dutch aggression, however, were in the East Indies and in the Americas, and the effective assertion of Dutch power against Portugal in western Africa was a by-product of the success of the Dutch West India Company in destroying Spanish naval power in the Caribbean and in embarking on the conquest of the plantation colony that the Portuguese had established in Brazil. As a result, by the end of the 1630s the Dutch had established themselves as principal suppliers and customers of the Spanish plantations in the Caribbean, while in Brazil they were themselves in possession of a plantation colony.

The production on American plantations of tropical produce, of which sugar was the most important, and especially the marketing of this produce in western Europe, were extremely profitable activities. But plantation agriculture in the tropics required large and regular supplies of cheap labour. America did not have these, but, just across the Atlantic, western Africa seemed to have relatively great quantities of productive labour. As early as the 1450s, the Portuguese had begun to transport some African slaves to supplement the meagre labour resources of their own country (especially of the southern provinces they had reconquered from the Moors), and their own plantations in Madeira, the Cape Verde Islands, and, ultimately, on the islands of the Gulf of Guinea had come to be dependent on African slave labour. The Spaniards, and subsequently other Europeans, in America thus naturally came to look to Africa to make good their labour shortage, and a slave trade to the Caribbean had commenced on a small scale in the 1520s.

Spain had little in the way of trade in Africa itself, so the authorities gave out contracts for the supply of slaves to other merchants, and the ultimate suppliers were usually Portuguese. From the 1570s onward, Portugal's slave traders had a further American market in their own colony of Brazil. The large slave population on their Gulf of Guinea islands was getting out of control, with the result that many Portuguese planters were abandoning these islands and reestablishing their activities in Brazil.

By the time the Dutch West India Company entered the scene in the mid-1620s, in all probability about 400,000 slaves had been imported into the Americas, and the annual volume of imports had risen to about 10,000 a year. This was a sizable business compared with the earlier trades in African slaves to Europe (which had virtually ceased by the 1550s, when perhaps 50,000 slaves had been imported) or to the Atlantic and Gulf of Guinea islands (which by the 1620s had probably received rather more than 100,000 slaves, but whose imports were then less than 500 a year). The demand for slaves in the Americas was also beginning to increase rapidly. In the wake of the Dutch defeat of Spanish naval power, English and French colonists were beginning to settle the smaller Caribbean islands and were seeking to exploit their soils for tropical agriculture with as many slaves as possible, while Spanish official restrictions on the volume of slave imports in their territories were hardly effective.

The labour needs of the plantations it had conquered in Brazil made it imperative that the Dutch West India Company should begin to secure slaves from Africa, and it very quickly recognized that the supply of slaves to European colonists elsewhere in the Americas was an extremely profitable business. To ensure its sources of supply, the Dutch company embarked on the conquest of all the Portuguese bases on the western African shores. Some of these, for example the island of São Tomé in the Gulf

Portuguese and Dutch rivalry

Comparative statistics in the slave trade

of Guinea, were subsequently lost to it, but by 1642 the Dutch were firmly in possession of the Portuguese forts on the Gold Coast, and they dominated Europe's trade with western Africa from Cape Verde to the Niger delta. By the 1660s probably as many as 15,000 African slaves were being landed in the Americas each year. Nearly half of this trade was Portuguese, for this nation had by then recovered its possessions in both Brazil and Angola and had a near monopoly of the trade south of the equator, but the remainder, the growing part, was in northern European hands.

The Dutch West India Company's activities in the Atlantic slave trade aroused interest throughout the ports of northwestern Europe, and soon merchants from France, Britain, Germany, and Scandinavia, as well as private Dutch traders, were competing with the Dutch company. French and British competition soon became of major importance. Both countries were resentful of the growing economic power of the Netherlands that was based on foreign trade, and both possessed colonies in the Americas. Their governments decided that their colonists should not be dependent on Dutch merchants for their supplies of labour (nor, for that matter, for capital or for the marketing of their produce in Europe). Through grants of monopolies of their nations' trade with western Africa or the West Indies, French and English merchants were encouraged to form companies strong enough to challenge the power of the Dutch West India Company, and these challenges were supported by the warships of their respective royal navies.

Between 1652 and 1713 there was a succession of wars involving France, Britain, and the Netherlands. The main battles were usually fought far away from Africa, but throughout the period the traders of each nation sought to increase the number of their trading posts on the western African coast and to deny trade to their rivals. A large number of new forts was built, and these forts were constantly changing hands.

By 1713, however, a pattern of European activity had emerged that was to remain more or less constant until the Atlantic slave trade was brought to an end during the first half of the 19th century (and that was considerably to influence the subsequent partition of western Africa between European empires). The hold that the Dutch had established over Europe's oceanic commerce was destroyed, and Britain and France competed with each other Anglo-
French
competi-
tion for its inheritance. The Anglo-French wars of the 18th century had less direct effect on western Africa than did the earlier wars involving the Dutch, but the development of trade with western Africa to supply slaves for their American colonies continued to be an important aim of both countries.

France emerged as master of the coastal trade north of the Gambia River, where it had taken the strategic naval base on Gorée Island, close by Cape Verde, from the Dutch in 1677 and was developing a fort and town at Saint-Louis at the mouth of the Sénégal River as a major commercial centre. By and large, however, this part of the coast produced relatively few slaves, and the French companies operating from Saint-Louis sought compensation by developing the trade of the Sénégal basin in gum and hides and by penetrating upriver toward the alluvial goldfields of Bambuk. Little of permanence was achieved in the 18th century, however, in part because of the resistance of the local peoples, but mainly because of the growing naval power of Britain. Britain's strategic interests almost invariably led it to occupy Gorée and Saint-Louis in each of the sea wars of the century, and from 1758 to 1779 its government attempted to consolidate its conquests there into a formal colony.

But the Colony of the Senegambia was not a success. Britain's merchants were not willing to follow up its naval and military successes in this region, and French traders were allowed to creep back. The main results of Britain's initiative were to interrupt French imperial ambitions in the Sénégal valley for nearly a century, and, on the British side, to contribute to a growing opinion—associated particularly with the loss of the North American colonies and the views of Adam Smith—that formal empire was less important and valuable than the independent operations of a growing host of individual British traders, operating wherever there was profit to be found under the general cover of British naval supremacy.

British traders competed with the French on the Gambia River, where both nations' companies maintained forts, and also established themselves to some extent on the coast of Sierra Leone, but initially the main centre of British activity in western Africa was the Gold Coast. Because the Gold Coast had been the scene first of the major Portuguese and then of the major Dutch successes in western African trade, its peoples were better organized than most to provide European traders with what they sought, and the fact that they could supply gold as well as slaves remained of major importance.

During the period of intensive competition in the later 18th century, the number of major European forts on this 300-mile-long coastline had risen to approximately 30. The Dutch West India Company still had more Gold Coast forts than anyone else, and these by and large were the strongest and best maintained. But their headquarters at Elmina was now rivaled by the British castle at Cape Coast only a few miles away, and indeed almost every Dutch fort had an adjacent British establishment competing with it. The French never succeeded in getting a permanent foothold on the Gold Coast; Swedish and German ventures eventually came under Dutch or British control, and traders from Denmark retained forts only on the eastern Gold Coast, where there was little gold and slaves were the main articles of trade.

Although the formal position of the Dutch on the Gold Coast remained strong throughout the 18th century, and indeed into the 19th century, they steadily lost trade to the British merchants. One reason for this was simply that Britain had displaced the Netherlands as the major naval and sea-trading power in western Europe and, through the developing Industrial Revolution, was better able to supply overseas traders with cheap goods for the world market. The British were also more successful than their rivals in adapting the nature of their operations to changing conditions of trade. The Dutch
give way
to the
British

The Dutch on the Gold Coast and the French in Senegal tended to hold to the view that the African trade should be conducted through large corporations, which had military and administrative as well as commercial responsibilities and which were rewarded for these by their monopoly rights. Such companies had been essential if the original Portuguese monopoly of African maritime trade were to be broken, or if the national interest in it were to be maintained in the subsequent period of militant European rivalry for the trade. The intensity of the competition during about 1650 until about 1713 had made the business of building or capturing and of maintaining and defending coastal forts extremely expensive. On the other hand, the breakthrough into trade with Africans had been made, and the ever-increasing demand for slaves led to a great widening of European commercial activities along the coast. Thus by the beginning of the 18th century there were few parts of the coastlands where African rulers and merchants were not prepared and organized to sell slaves in some numbers.

Hence the future lay not with the cumbersome companies, with large amounts of capital locked up in costly forts, but with a host of small European traders, who were not tied to particular shore installations but were seeking for the best terms of trade they could find along the coast. This type of European trader was naturally welcomed by African rulers, newly embarking on trade with the Europeans, who had no wish to see the latter establish permanent bases on their coasts, which, as the Gold Coast forts had done, might develop political claims to challenge their own traditional jurisdictions. It was the British traders, protected by their country's command of the sea and backed by the abundant supplies of goods and capital produced by its revolutionary economic growth, who were most successful in exploiting the new pattern of trade.

The old monopoly companies had never been strong on the coast between the Gambia River and the Gold Coast. In the north this was largely due to the effects of the

breakdown of the early Portuguese attempts at controlling the trade. Farther south, the territories of modern Liberia and Côte d'Ivoire had not excited much interest among early European traders. Their coastline was treacherous for navigation, and their thick forests supported a scanty population that was little organized for commerce. Such trade as had developed, principally in ivory and in agricultural produce, did not warrant much investment in shore establishments. Thus, as the American demand for slaves increased, the Upper Guinea coast became frequented by increasing numbers of small traders who competed bitterly with each other for slaves.

The greatest opportunities for the new class of individual European traders lay not to the west but to the east of the Gold Coast, where populations were denser and much better organized, not only politically but also commercially and specifically in their access to developed trade routes linking them with inland centres of population, production, wealth, and organized government. European sea captains knew this coast well enough, for the best sailing routes to return to Europe from the Gold Coast ran via the Gulf of Guinea and its islands. European trade had been held back there only because there had been no staple export to compare with the gold of the Gold Coast. Nevertheless, their ships' need of provisioning for the return voyage, the local trade between the Niger delta and the Gold Coast, and the early slave trade to São Tomé and Brazil had led to a demand developing among the African peoples for European manufactures such as metals and metalware, cloth, guns and ammunition, and spirits, and there was a network of traders and trade routes to expand trade with the interior if a staple African export could be found.

The rapidly increasing demand for slaves as West Indian and American plantation production began to boom provided this staple. In the second half of the 17th century, Dutch, French, English, and Portuguese traders became increasingly involved in trade on the coast between the Gold Coast and Benin, which soon in fact received the name of the Slave Coast. Initially the company-fort pattern of trading was applied here, but it never took root to the extent that it had done on the Gold Coast, in part because the local rulers insisted that the forts should be built in their own inland towns. As the slave trade further developed, both on the Slave Coast itself and also further east, in the Niger delta region, it became typically an enterprise of individual European or American traders or small partnerships, who acknowledged the authority of the local rulers and paid the fees and duties these demanded.

As has been seen, in the 1620s, on the eve of the great growth of the Atlantic slave trade that followed the Dutch entry into it, the number of African slaves reaching the Americas was about 10,000 a year. In the last quarter of the 17th century, the average annual American import was some 25,000, and the total number of African slaves imported during the century has been estimated at 1,494,000. In the following century it operated on a vastly greater scale; the best available estimate for the number of Africans imported into the New World in the 18th century is some 5.2 million. After about 1815, and especially after the 1840s, the measures taken to outlaw European and American slave dealing, and also—more significantly—the possession of slaves in the Americas, began to take effect, and in the 1860s the Atlantic trade was finally brought to an end after a further 2,780,000 slaves had been landed in the Americas.

The peak of the Atlantic slave trade seems to have been reached in the 1780s, when on average some 78,000 slaves were brought to the Americas each year. About half these slaves were transported in the ships of British merchants. Their nearest competitors, the French and Portuguese traders, carried each about a fifth of the total. Subsequently the French trade (and also the Dutch and Danish trades) virtually ceased as a result of the British blockade of Europe during the Revolutionary and Napoleonic wars of the turn of the century, and the British predominance was even more marked, possibly 60 percent of the trade being in British hands, compared with perhaps 25 percent for Portugal and 15 percent for North American merchants.

The slave-trade era. All the estimates for the volume of the Atlantic slave trade that have been given so far are for numbers of slaves landed in the Americas, as such numbers are generally more readily ascertainable than figures for slaves leaving Africa. A fair proportion of these slaves never reached the other side of the Atlantic because of deaths from disease, maltreatment, or maritime disaster. Evidence from the 18th and 19th centuries, when the vast majority of the slaves were transported, suggests that on average the loss may have been about 15 percent; in earlier times losses are likely to have been higher, perhaps averaging 20 percent.

Not all the slaves were taken from western Africa as defined in this article. Considerable numbers were always taken from Africa south of the equator, and in the 19th century the measures taken to stop the North Atlantic slave trade were quicker and more effective than those against the trade across the South Atlantic. It seems safe to suggest that, up to and including the 18th century, 60 percent of the slaves were taken from the western African coasts from the Sénégal River to the Cameroons and that in the 19th century the proportion dropped to about one-third. It is thus possible to arrive at the following estimates for the loss of population to western Africa.

Population Loss Due to Atlantic Slave Trade

	from Africa as a whole		from western Africa north of the equator	
	arriving overseas	leaving Africa	percentage	estimated total
Before 1600	290,000	370,000	60	220,000
1601–1700	1,490,000	1,870,000	60	1,120,000
1701–1810	5,150,000	6,130,000	60	3,680,000
After 1810	2,780,000	3,270,000	33	1,090,000
Total	9,710,000	11,640,000	—	6,110,000

It is not easy to assess what effects such a loss of population may have had on western Africa and on the course of its history. In the first place, it must not be forgotten that almost all statistics concerning the slave trade involve some degree of estimation. Those used here are based on the analyses of the available data by the American historian Philip D. Curtin and by the Canadian historian Paul E. Lovejoy; they are unlikely to be more than ±20 percent from the reality.

Second, there is really no means of knowing the size of the population of western Africa at any time during the period of the Atlantic slave trade. Working backward from the population data available in the 20th century (which are not themselves always very reliable), and from the evidence these provide for rates of growth, it is possible to suppose that at the beginning of the 18th century, when the Atlantic slave trade was entering its dominant phase, the total population of western Africa may have been about 25,000,000, and that its natural rate of increase may have been some 0.15 percent per annum. Although these estimates can be little more than guesses, they do tend to suggest that the commonly held idea that the export slave trade actually depopulated western Africa is not likely to be right.

When the slave trade was at its height during the 18th century, the export of slaves was averaging 45,000 a year. This loss would have been about equal to the assumed natural increase in population, so that the effect might have been to have checked population growth rather than to have actually diminished the population. In earlier centuries, or in the 19th century, it would not even have had this effect: population would have been growing, albeit more slowly than with no export of slaves.

But these are gross calculations that take no account of the uneven selection of slaves for export. Since the American planters, and hence the slave traders, looked in particular for fit slaves in the prime of life, between about 15 and 35 years old, it may be argued that robbing western Africa of people particularly from this group of its population would especially tend to reduce births and thereby reduce the capacity of the population to maintain its numbers. On the other hand, however, the planters preferred their slaves to be male, and only about a third of

The Slave Coast (marginal label)

Comparative statistics of population loss (marginal label)

those exported were women. Thus, since western African men who could afford it were polygynous, the birth rate may have been less affected than might have been expected. There is also evidence to suggest that the fitter or more intelligent slaves were often kept at home, and that less fit individuals were in many ways prepared to deceive the European buyers as to their age or condition.

It can also be argued that, since some parts of the coast saw the export of many more slaves than did others, the regions adjacent to these coasts suffered much more severely than the overall figures for western Africa as a whole might suggest. In the peak period of the 1780s, the distribution of exports along the coast was approximately as follows: from the Senegambia and Sierra Leone, about 7,000 slaves a year (about 15 percent of the total from western Africa as a whole); from the Gold Coast, about 9,400 (20 percent); from the Slave Coast and the Benin region, about 16,000 (35 percent); and from the Niger delta and the Cameroons, about 13,400 (29 percent). The three last zones—Lower Guinea—today have populations as dense as any to be found in tropical Africa, and the available evidence suggests that their population was also relatively great in the 18th century—certainly by and large denser than that of most parts of Upper Guinea.

It is therefore possible to conclude that the largest numbers of slaves came from just those regions that could most afford to export population. It is also unlikely to be a coincidence that it was this same area—from the Gold Coast to the Cameroons—which was the most highly developed coastal region in terms of government, economic production, and trade. It was only in areas of low population and poor indigenous organization that foreign slave traders ever needed to set out to capture slaves for themselves. This naturally made the Africans involved hostile to further dealings with the traders, while it also tended to reduce the power of the population to maintain and feed itself, so that in both cases supplies of slaves were ultimately fewer. For the most part, the European traders bought the slaves they needed from African merchants and rulers who had organized to offer slaves for sale.

About half these slaves were unfortunates in their own societies: criminals, the mentally or physically handicapped, debtors or those who had been sold for debt or pledged as security for a debt, those who had offended men of power or influence, or simply those who in some way had become outcasts from the family and tribal systems. Selling such people was usually simply an alternative to keeping them in some kind of servitude in domestic society or, in more extreme situations, condemning them to execution or to serve as human sacrifices in the festivals of ancestral or land cults.

The remainder of the slaves exported were strangers to the societies that sold them, sometimes unwary travelers or border villagers who were kidnapped, but for the most part prisoners of war. Europeans sometimes argued that African kings went to war often with the prime purpose of securing slaves for the slave trade. In the 19th century, when the Europeans themselves had outlawed the slave trade, this argument was used to justify the advance of European colonial rule. On the other hand, in the 18th century, some European slave traders claimed that the acquisition of slaves was simply a consequence of wars which were natural occurrences. From this they argued that they were actually doing a service to such captives and to humanity by buying them and selling them into hard labour on the American plantations. They claimed that they were rescuing the slaves from the danger of being executed or of becoming human sacrifices and that slavery under civilized Christian masters was preferable to slavery in primitive, pagan African society.

Despite the speciousness of the latter claim, the 18th-century slavers' argument seems nearer the truth than that of the 19th-century abolitionists. African wars, like wars anywhere else, were the consequence of rivalries for wealth and power between states. Whereas elsewhere the wealth and power of a monarchy might be measured in terms of the amount of territory it controlled, or in terms of the monetary value of its resources, the prime measure of both power and wealth in Africa was people. By and

large land in Africa had very little economic value. There was almost invariably far more land available than there were people to cultivate it or to develop its mineral and other resources. The key to the strength of a kingdom thus lay in its ability to gain control of human energy, and an obvious way to do this was to take people away from its neighbours and rivals. This, indeed, was how western African kingdoms had come to be built up, by the natural rulers of particular small kinship groups securing for themselves and their units more clients and slaves than their neighbours, and by using them to extend their power over these neighbours and even farther afield.

People then were the important resource. Often, indeed, a person was the unit of value in which other resources were measured: thus the value of horses, or guns, or parcels of trade goods was often expressed in terms of the numbers of slaves (*i.e.*, disposable people) for which they might be exchanged. If more people were available, then more land, or gold or iron or salt, might be exploited or more trade might be done (the environment was hostile to transport animals, so that trade depended heavily on the availability of porters and canoemen). Thus there would be greater surpluses available to support the monarch, his household, his administration, and his army, and to maintain specialized manufactures, crafts, and services.

The purpose of wars was thus to increase the power and wealth of a kingdom by increasing its human power and diminishing that of its rivals. The ruling philosophy cannot therefore have been one favouring the export of slaves. But it was one in which the economic value of a person was very well established. With the growth of trade, and especially of international trade which made available desirable commodities that seemed as valuable or sometimes more valuable than people, it was natural for African kings and their traders to think of selling some men and women in exchange for these commodities, and especially so if the foreign merchants who offered these commodities were themselves interested in acquiring slaves.

This situation had first arisen, and at a very early stage, in the trans-Saharan trade. Labour was needed to work the Saharan salt deposits, and the civilizations of the Mediterranean and Middle East had long had a demand for slaves. Some North African and Middle Eastern exports, particularly perhaps horses, were so valuable in the Sudan that its kings were quite ready to exchange some of their scarce human power to secure these. However, the problems involved in marching slaves across the Sahara with its scarce and widely separated resources of water were formidable. Although reliable estimates are lacking, it is generally supposed that the trans-Saharan slave trade could rarely if ever have transported more than 6,000 or 7,000 slaves a year. After the middle of the 17th century, however, the demand of the Atlantic trade for slaves was practically insatiable, and, as has been seen, at its peak during the 18th century, each year about seven times as many slaves were leaving the western African coasts.

A high proportion of these slaves, nearly a third, were being exported—as has been seen—from the Niger delta region. The communities of Ijo (Ijaw), Ibibio, and Efik fishermen and salt makers, who controlled the waterways to the interior, developed city-states whose whole fortunes came to be bound up with the slave trade. Most of their slaves were brought from their immediate hinterland. It is probably significant that some of this hinterland, particularly that inhabited by the Igbo (Ibo) and the Tiv, today has the highest population densities to be found anywhere in tropical Africa—some Igbo densities being as much as 1,500 persons to the square mile. Igbo country is not rich in natural resources, however, and its water supplies are poor. In the 20th century one result has been that many Igbo have emigrated to sell their labour in other parts of Nigeria. It is not unreasonable to assume that something of this population pressure may have already been evident during the slave-trade era and that many communities in the hinterland of the Niger delta could only survive and prosper by selling some of their people.

This was almost certainly a unique situation. It is doubtful whether there could have been anywhere else in western Africa a buoyant surplus of labour to encourage this kind

of exploitation. It is noteworthy, indeed, that, although the American demand for slaves was rising steadily from about 1630 onward, every other part of the coast seems quite soon to have reached a figure for slave exports which thereafter remained more or less constant until the 19th century. Then two things happened: first, there was a breakdown in the system of law and order that had hitherto operated in Yoruba country to the west of the Niger delta, with the result that exports from the Slave Coast began to increase; and second, after the early 1860s, the American demand fell off sharply. There is a strong implication that in the 17th and 18th centuries the other major slave-exporting regions with relatively large populations had developed politico-economic systems which were able more or less consciously to calculate the balance of advantage for themselves of engaging in the export slave trade. By and large their conclusion seems to have been that it was more profitable to exchange some of their labour for European goods than it was to keep it all at home, but that it was dangerous to export more than a certain controlled quantity.

The Atlantic slave trade was not simply a rape of African labour to serve European purposes in the Americas. In any case, slaves were not the sole African exports by sea during the slave-trade era. Gold, gum, hides, timbers, palm oil, and other commodities were also traded, and the European merchants needed to buy large quantities of provisions to feed the slaves during the Atlantic crossing. The slaves and other exports had to be purchased, and in exchange Africans received supplies of other goods—cloth, metals, tools, knives and other hardware, guns and ammunition, beads and small manufactures, tobacco and spirits—that, however much their prices may have been inflated in relation to their cost in Europe or America, were thought by their purchasers to be at least as valuable as the slaves or other goods they had sold.

From the African point of view, the main importance of the slave trade may have been that it led to a great growth of all kinds of trade at the coasts and to a considerable stimulation of economic and political activity and organization for some distance into the interior of Guinea, a region which had hitherto been remote from the main centres of trade in western African history, which had been in the Sudan. It is difficult to quantify this growth of commercial activity, but coastal exports and imports combined, negligible prior to about 1500, may—in contemporary values—have been worth something like $3.5 million a year by 1700 and $8 million or more by 1800. This was a considerable trade by the standards of the time, as can be seen from comparison with an estimate in the 1850s of the value of the trade of Kano, then the most prosperous of the Sudanic kingdoms, at some $500,000 a year.

Some consequences of this rapid increase of trade on the Guinea Coast were fairly general. One was the appearance on the coast itself of a new class of African merchants, who freed themselves from some of the restrictions of traditional society and were able to accumulate personal wealth and power to rival that of the local kings. Sometimes, indeed, as at Komenda on the Gold Coast or at Opobo in the delta, the new men actually set themselves up as kings. This development owed much to the direct influence of the European trade on the coast. Some Europeans settled more or less permanently in Africa, married local women, and created new merchant dynasties, such as the Brews of the Gold Coast. Others of the new men were former slaves who had returned from America, particularly perhaps from Brazil to the Slave Coast. Many were local Africans, but usually men who had started by gaining useful contacts and training in the service of European merchants. All the new men were experienced in European ways and often secured for their sons elements of a European education.

The growth of Guinea's international trade encouraged the spread and acceptance of regular systems of currency. Many, perhaps most, of the Guinea currencies were already extant on the coast when the Europeans arrived, but the growth of trade meant that certain of these became the sole acceptable currency within relatively large and well-defined areas, such as iron bars in Upper Guinea

and much of the Niger delta, ounces of gold dust on the Gold Coast, and cowrie shells on the Slave Coast. Another development was the emergence on a considerable scale of production for sale. In Asante (Ashanti), for example, some villages were given over to the production of a particular commodity, such as cloth, and some of the chief men ran plantations with slave labour (as also, in the 19th century, did the kings of Dahomey).

The emergence of the trading city-states of the Niger delta represented a social revolution as well as a political innovation. The kinship system gave way to the "House" system, by which both freemen and the large numbers of slaves needed to operate trading canoes and strategic and trading settlements were bound together by common economic interests into large corporations headed by the leading merchants. On the Gold Coast and Slave Coast, however, political development was more akin to that which had earlier taken place in the Sudan under the influence of trans-Saharan trade.

Behind the Gold Coast the original centres of Akan trade and power had been north of the forest and northward-looking. The growth of trade at the coast led to new developments among the settlements in the forest, which had hitherto served only to produce gold and kola nuts for the northern trade. In the 17th century three major forest kingdoms emerged: Denkyera in the west, Akwamu to the east, and between them, Akyem. These competed with each other in expansion parallel to the coast to control as many as possible of the paths of trade to the European forts. Akyem lost, while Denkyera achieved such an overweening power that some of its northern tributaries secured guns and new techniques of political and military organization from Akwamu and rose in revolt. This was the effective origin of the new monarchy of Asante based on Kumasi, situated in the central forest where the major trade routes from the Gold Coast converged and met with the major routes of the Hausa and the Mande-Dyula traders from the north.

By the beginning of the 18th century the power of Denkyera had been crushed, and in the next 70 years Asante armies went on to build up an empire that in the north engulfed Bono and Gonja (Guang) and levied tribute on Dagomba and in the south incorporated or made tributary virtually all the small states that had been involved in the rise of Denkyera, Akyem, and Akwamu. The only part of modern Ghana that was not under the sway of Kumasi was the central coastlands, where the small Fanti (Fante) states, gaining some measure of protection from their close association with the various European forts, began to come together in a federation to resist Asante influence.

As the Atlantic trade began to expand east of the Gold Coast to the Slave Coast, similar political developments began to manifest themselves in its hinterland also. Toward the end of the 17th century the northernmost Yoruba kingdom, Oyo, began to turn away from its traditional rivalry with the adjacent savanna kingdoms of Nupe and Borgu and to use its cavalry to assert control of the trade routes through the open country southwestward to the small Aja states on the coast in which the Europeans had established trading posts. A measure of control was also asserted more directly to the south over other Yoruba peoples and kings in the forest. Here a boundary was established with the kingdom of Benin, which in the later 17th century decided that it was in its interests to open up its ports to European merchants and to sell slaves to them to secure a share of the goods they were offering.

By the early 18th century strains caused by the virulent competition between the European traders and their African associates were leading to the dissolution of traditional social and political controls among the Aja, who had a number of small kingdoms under the nominal leadership of the king of Allada. The resultant disorder was not to the liking of the kings of Dahomey, the youngest of these monarchies, who, in colonizing the northern marches of Aja territory, had evolved much more authoritarian and militant forms of government and society. Between 1724 and 1734, Dahomey enforced its concepts on the other Aja peoples by conquest and began to build up a centralized state to control the entire Slave Coast.

Other trading commodities

Systems of currency

The southward expansion of Oyo

Initially Dahomey, wishing to conserve labour, was reluctant to sell slaves to the Europeans. This was not to the liking of Oyo, whose foreign trade was dependent on its being able to sell slaves to the Europeans on the Slave Coast. Nor was it really in the long-term interests of the centralized trading system of the Dahoman kings themselves, for these had little but slaves to offer in return for the guns and other goods they needed to buy from the Europeans. From 1726 to 1748 the consequence was continual warfare on the Slave Coast, the ultimate results of which were that Dahomey was led by force of arms to recognize Oyo suzerainty and that the slave trade became firmly established, both under strict royal control in Dahomey's port of Whydah (Ouidah) and, increasingly, in ports beyond its control to the east, such as Badagri and Lagos.

The armies of Denkyera, Akwamu, Asante, and Dahomey all made use of firearms, and Akwamu seems to have been a pioneer in the development of tactics suited to the new weapons. The Portuguese had not imported guns into western Africa on any scale and as a matter of policy had sold them only to their allies. In the highly competitive trading situation that followed the Dutch breaking of the Portuguese monopoly, all the European trading nations vied with each other to sell guns, and they soon became an essential article of trade.

The muskets exported to western Africa were cheap varieties specially made for the African market. They were undoubtedly serviceable for hunting and for the protection of crops from the depredations of birds and wild animals, but it is debatable how significant their acquisition was in the rise of the new Guinea kingdoms of the 17th and 18th centuries. It is notable, for instance, that Oyo's military victories were attributed to its employment of cavalry and that it was consistently successful against Dahomey, whose soldiers were equipped with muskets.

Guns as symbols of prestige as well as power

From the African point of view, guns were expensive—though less perhaps to buy than to keep in working order and supplied with powder. In this respect, guns were not dissimilar to horses and, like horses, they became the particular prerogative of kings and their henchmen, symbols of prestige but also elements in the growth of royal power at the expense both of subjects and of unfortunate neighbouring peoples who did not evolve state systems. It followed that the trade in firearms—and also in those African exports, such as slaves and gold, which were most in demand by the European sellers of firearms—tended to be under strict royal control. Similarly, competition to secure supplies of guns and ammunition—as of horses in the Sudan—and to deny such supplies to rivals was a factor of some significance in the new era of power politics in Guinea.

By the 18th century the kingdoms and empires of Guinea, especially those of Lower Guinea, though commonly less extensive, were as powerful as those that had been established in the western Sudan. As with the latter, control of trade with the outside world had been an important element in the growth of these states. However, the relationships between the growth of trade and the growth of states in the two systems, those of Guinea and of the Sudan, were not entirely identical. The rise of the Guinea states, for instance, was associated with a growth of trade that was particularly dependent on the growth of a demand for one particular African export, slaves. Any cessation of this demand was therefore likely to create strains for the Guinea states; and Asante, Dahomey, and Oyo had hardly established paramountcies in their areas when Europeans began seriously to question both the morality and the economic value of slave labour.

It is also noteworthy that the Guinea peoples did not generally establish networks of itinerant traders extending far beyond their homelands, as the Mande and Hausa had done. The Asante, Dahomey, and Benin trading systems seem essentially to have been state corporations operating under royal control or license only within the boundaries of their political influence. The northern limits of the Guinea trading system hardly extended more than 300 miles from the coast. Conversely, Mande–Dyula and Hausa traders had ventured far beyond the political and military limits of their kings' authority (which, in the case

of the Hausa, were always very restricted). Even after the rise of the Atlantic trade and of the Guinea kingdoms, traders from the north continued to be of prime importance to the commerce of Guinea and, sometimes, to its political life. The community of Muslim northerners settled in Kumasi, for example, sometimes played a significant role in Asante politics, and the northern trade also led to Islām gaining important ground among the Yoruba. Thus the Guinea states were also likely to be affected by any important changes in the political and economic life of the western Sudan.

THE ISLĀMIC REVOLUTION IN THE WESTERN SUDAN

The Moroccan occupation of the Niger Bend in 1591 meant that the domination of the western Sudan by Mande or Mande-inspired empires—Ghana, Mali, Songhai—which had persisted for at least five centuries, was at last ended. The Songhai kings were pushed southeast into their original homeland of Dendi, farther down the Niger close to Borgu, and Mande political power was limited to the so-called Bambara—*i.e.,* "pagan"—kingdoms of Segu (Ségou) and, later, of Kaarta, upstream and to the west of Macina. In and around the Niger Bend itself, the long-term effect of the Moroccan conquest was to open up the Domi-
nance of
Tuareg country to the Tuareg and Arabized Berber tribes of the Saharan fringes. By the middle of the 18th century the and descendants of the Moroccan conquerors, who had settled Berber down in the Niger Bend cities as a ruling caste, the Arma, tribes had become tributary to the desert pastoralists.

The same tribes operated, or at least profited from, the trans-Saharan trade, and some of them had acquired leading positions in western African Islām. The Kunta tribe of Arabized Berbers had become preeminent in both these respects by the 18th century. It dominated the salt trade to Timbuktu, and in the person of Sīdī Mukhtār (died 1811) it had produced a spiritual leader so respected among the Muslims of the western Sudan that the Kunta were able to exercise on the quarrels between the pastoral tribes a mediating influence which was clearly to the general benefit of commerce and urban society.

Mukhtār's position was due to qualities of learning and holiness that were in part personal but also in large measure due to his leading role in the Qādirīyah, one of the Muslim brotherhoods (tariqas) in which particular traditions of both sanctity and learning were passed on from teacher to teacher. These brotherhoods or religious orders had arisen with the growth, from about the 11th century onward, of mystical currents of Muslim thought (especially in eastern Islām, where the Qādirīyah had begun). Mysticism proved to be congenial to Berber society in North Africa (where the Tijānīyah order evolved in the 18th century), and from here the tariqa entered the Sahara, arriving in western Africa by the beginning of the 16th century.

Hitherto Islām had been spread in western Africa essentially by merchants who, in order to secure their livelihood, chose to accommodate themselves and their religion within the pagan social and political framework that existed where they settled—which for the most part was only in the towns. But with the coming of the tariqa—of which the Qādirīyah was one of the first and, until the Tijānīyah began to advance in its tracks in the 19th century, certainly the foremost—western Africa began to experience the growth of organized groups of devout Muslims who were both specifically trained and morally compelled to work toward a true Islāmic society. Moreover, if the people and their rulers remained irresponsive or hostile, it was the Muslims' duty to preach the doctrine of conversion by force, through the jihad, divinely justified war or rebellion against rulers who were pagans or not true Muslims.

This doctrine was particularly attractive to the Fulani, who, as has been seen, were scattered in stranger communities between the agricultural settlements throughout the western African savannas. As the wealth, organization, and power of agricultural and urban society increased, so there was less scope available for the free movement of the Fulani cattle and less freedom for their herdsmen. The Fulani were subject to increased pressures to pay rents, taxes, and services to the rulers of the settled commu-

nities who, from the Fulani point of view, were aliens who had no natural right to these things. Although the bulk of the Fulani were pagans, they were, as pastoralists, naturally open to influence from the Saharan pastoralists who were Muslims and among whom the tariqa had been established. The Fulani also had ethnic links with the long Islāmized Tukulor of the far west, and they had a considerable class and influential Muslim clerical class of their own. The Fulani clerics were thus particularly receptive to the doctrine of jihad and, throughout the Sudan, could ally themselves with considerable numbers of disgruntled and mobile pastoral kinsmen to make jihad a military reality.

The
Fulani
jihad

The earliest known Fulani jihad occurred in Bondu, close to the Islāmized Sénégal valley, where in the second half of the 17th century Fulani clerics succeeded in taking over political power from local Mande rulers. Early in the following century, considerable numbers of Fulani began to do the same in alliance with the local Muslim Mande traders in the nearby Fouta Djallon. By about 1750 a Muslim theocracy had been erected whose leaders were soon engaged in organizing trade to the Upper Guinea coast on which European traders were active. In the second half of the 18th century the same pattern was repeated in the Fouta Toro, the homeland of the Tukulor, for there, though the dispossessed rulers were Muslims, as a group they were too self-interested and exploitative to suit the clerics.

News of these developments in the westernmost Sudan naturally spread through the Fulani diaspora to more easterly territories influenced by the teaching of Sīdī Mukhtār and other like-minded tariqa divines. In 1804 the most famous of the western African jihads was launched in Hausaland by Usman dan Fodio.

Usman was the leading Fulani cleric in Gobir, the northernmost and most militant of the Hausa kingdoms. This was in a disturbed state in the 17th and 18th centuries. The growth of Tuareg power in Aïr on its northern frontiers had led the Gobir ruling class to seek compensation to the south and southwest, in the territories of Zamfara and Kebbi. There the breakup of the Songhai empire had led to a power vacuum, which had been an encouragement to Fulani settlement. The kings of Gobir, like other Hausa monarchs, were at least nominally Muslims, and for a time Usman had been employed at their court. He then used the influence he had gained to develop a Muslim community of his own, some miles away from the capital, governed according to the strict principles of law preached by the Qādirīyah. The kings of Gobir gradually came to the conclusion that they could not afford to tolerate this independent jurisdiction within their unsettled kingdom and began to take steps against the Muslim community. By 1804 the situation became such that Usman felt he had no alternative but to declare a jihad and to adopt the role of an independent Muslim ruler (*amīr al-mu'minīn* or, in Hausa, *sarkin musulmi*).

Both sides appealed for wider support. While the Hausa kings proved incapable of concerted action against the movement of Islāmic rebellion, discontented Fulani and oppressed Hausa peasantry throughout Hausaland welcomed the opportunity to rid themselves of vexatious overlords and arbitrary taxation. Within three years almost all the Hausa kings had been replaced by Fulani emirs who acknowledged the supreme authority of Usman. The most serious fighting was in and around Gobir itself, where the maintenance of large Fulani forces in the field alienated the local peasantry. Fortresses had to be established for the systematic reduction of the country, and in the process the old kingdom of Gobir was destroyed and two major military encampments, Sokoto and Gwandu, eventually emerged as the twin capitals of a new Fulani empire.

The rise of
the Fulani
empire

The core of this empire was composed of the three large former kingdoms of Katsina, Kano, and Zaria (Zegzeg), in which, together with the smaller former kingdom of Daura, a Fulani aristocracy had taken over the Hausa system of government and had brought it into line with the principles of Islām as stated by Usman. But the jihad had not stopped at their boundaries. Hausa clerics and adventurers joined with the Fulani in creating new Muslim emirates farther afield, among the pagan and hitherto

largely stateless peoples of the Bauchi highlands, for example, and in the open grasslands of northern Cameroon, where there were large numbers of Fulani. There the vast new emirate of Adamawa was created. In the south Fulani and Hausa clerics intervened in a succession dispute in the old pagan kingdom of Nupe and by 1856 had converted it into a new emirate ruled from Bida. There had also been considerable Fulani and Muslim penetration into northern Yorubaland, and, in about 1817, its governor rashly invoked Fulani and Hausa aid in his rebellion against the king of Oyo. The governor's new allies took over, the new emirate of Ilorin was created, and the disintegration of the Oyo empire was accelerated.

The only serious check to Fulani conquest was in Bornu. By 1808 the forces of Fulani rebellion and invasion had reduced its ancient monarchy to impotence. Bornu and Kanem, however, had their own clerical class and tradition, and in the latter province arose a new leader, Muḥammad al-Kānemī, who asserted that the Fulani clerics did not have a unique right to interpret Muslim law for the government of humanity. Al-Kānemī was able to inspire a spirited national resistance, which by 1811 had turned the tide against the Fulani. By 1826 he was the effective master of a new Islāmic state, though the traditional kings were maintained in office until 1846, when the puppet of the time rebelled against al-Kānemī's son and successor, 'Umar, but was defeated and killed.

Usman dan Fodio was a scholar and theologian who had little inclination for the political and military direction of the movement he had inspired. His main role was to maintain the jihad's spiritual and moral force and direction, and he left a remarkable memorial of this in his innumerable writings. The practical commanders of the jihad were his brother, Abdullahi, and his son, Muḥammad Bello, who were men of action as well as considerable scholars. These two eventually became joint viceroys of the new empire, Bello ruling its eastern half from Sokoto and Abdullahi the western half from a seat of government at Gwandu. They oversaw the installations of the provincial emirs, received tribute from them, and endeavoured to ensure that their governments and systems of taxation followed the principles of Muslim law and were not arbitrary and extortionate. Gradually the original scholarly and clerical impulse of the jihad weakened (though it was never wholly forgotten), and the emirs tended to become more representative of the military Fulani aristocracy, which tended to intermarry into the old Hausa ruling class. Standards of scholarship decayed and Hausa, rather than Arabic, became the language of administration. But for half a century or more after the jihad, some 200,000 square miles of territory enjoyed a unified system of relatively impartial law and administration, and this was much to the advantage of its agriculture, industry, and trade.

Both Sokoto and Gwandu were in the extreme northwest of the empire, where the jihad had had its origins and where it continued longest, for Kebbi was never entirely subdued. It is possible also that it was in this direction, looking up the Niger toward the Kunta and to the considerable Fulani population of Macina, that it was thought that there might be further advances. Doubtless it was for these reasons that Abdullahi settled at Gwandu with responsibility for the western empire. The main Fulani successes, however, were to the southeast in Bello's sphere, and it was Bello who in 1817 succeeded to his father's titles of caliph and *sarkin musulmi*.

When, about 1818, a jihad began in Macina, it was an independent movement led by a local Qādirī Fulani, Ahmadu ibn Hammadi. Ahmadu was certainly cognizant of Usman's jihad, and the circumstances in which his own movement was born were very similar to those that had occasioned the jihad in Hausaland. Ahmadu established an independent Muslim community that brought him into conflict with his local, pagan Fulani chief, who was unwise enough to call for help from his suzerain, the Bambara king of Segu. The result was a general rising under Ahmadu that established a theocratic Muslim Fulani state throughout Macina and extended to both the ancient Muslim centres of Jenne (Djenné) and Timbuktu.

The third major western African jihad of the 19th century

The jihad
in Macina

was that of al-Ḥājj ʿUmar Tal (c. 1797–1864), a Tukulor cleric from the Fouta Toro. As a young man, ʿUmar went on the pilgrimage (hajj) to Mecca (hence the honorific al-Ḥājj), and in all spent some 20 years away from his homeland. Twelve of these were spent at Sokoto, where he married a daughter of Bello's. He also spent some time with al-Kānemī in Bornu, and he shared with both men in the great revival of Muslim scholarship in the western Sudan. But ʿUmar had a wider experience of the Muslim world than either Bello or al-Kānemī, and he must have been acquainted with both the modernism of Muḥammad ʿAlī Pasha's regime in Egypt and the new puritanism of the Wahhābiyah in Arabia. Also while in Arabia he seems to have been appointed the western African caliph of the relatively new Tijānīyah brotherhood, which was appreciably more activist in its demand for reform than the Qādiriyah. About 1838 ʿUmar arrived home in the Fouta, where he quickly became estranged from the local clerics. In 1848 he moved away with such followers as he had to Dinguiraye, on the borders of the Fouta Djallon. There he built up a community of his own, attracting and training military and commercial adventurers as well as religious reformers. His community traded with the Upper Guinea coast for firearms and was consciously conceived as the nucleus for a new state. In 1852 the Dinguiraye community came into conflict with the adjacent Bambara chiefs. A jihad was launched northward through the gold-bearing valleys across the upper Sénégal, where in 1854 the Bambara kingdom of Kaarta fell. ʿUmar then turned west down the Sénégal toward his own homeland and the French trading posts. But he was repulsed by the French, and after 1859 he sought to join with the Fulani of Macina in the conquest of the more powerful Bambara kingdom of Segu. The Macina Fulani were opposed to the idea of a Tijāni power advancing into their own Qādirī zone in the Niger valley and even gave some aid to Segu. After ʿUmar's forces had conquered Segu in 1861, they continued eastward, and, finding that Ahmadu's somewhat autocratic and intolerant regime had estranged the longer established Muslim communities, they established ʿUmar's hegemony as far as Timbuktu (1863).

The empire of al-Ḥājj ʿUmar Tal In less than 10 years al-Ḥājj ʿUmar's armies had conquered an empire almost as large as that of the Sokoto Fulani. It does not, however, appear to have been as well founded. Outside of the Niger valley and the major trading settlements, the majority of its inhabitants were basically pagans who had only accepted Islām because they had been subjected to the shock of conquest by comparatively small bodies of well-armed and well-led adventurers. This was a different situation from that in which relatively large numbers of Muslim Fulani and Hausa had poured out from the old Hausa states into territories already prepared for them by the infiltration of Islām and the presence of Hausa traders and Fulani settlers. In ʿUmar's empire individual captains, exempt from taxation themselves, settled down to exploit their conquests as virtually independent fiefs. Along the Niger axis of empire there were both old, established Muslim towns and Fulani communities whose inhabitants regarded the Tijānī Tukulor as upstarts. In 1864 ʿUmar was killed attempting to suppress a Fulani rebellion in Macina, and for many years his son and successor, Aḥmadu Seku (d. 1898), had to compete for his inheritance with his father's numerous other relations and captains.

The most important result of ʿUmar's conquests was that they established the Tijānīyah as the most powerful tariqa in western African Islām, and this, together with the earlier consolidation of Muslim power in the east under Sokoto, ultimately ensured that Islām became the dominant religion throughout the western Sudan, and one capable of peaceful expansion deep into Guinea. Already circumstances had changed, however, since the Fulani cavaliers had built up the Sokoto Muslim empire. Al-Ḥājj ʿUmar's empire builders relied on horses for their mobility, but they were also musketeers who knew the value of trade with the Europeans at the coast. Even more significantly, they had already come into conflict with, and had been worsted by, European military and political power advancing inland from the coast.

THE GUINEA COASTLANDS AND THE EUROPEANS (1807–79)

In addition to the Islāmic revolution in the Sudan, the major themes of western African history in the 19th century are the successful campaign against the export of slaves, the trade that for the previous 200 years had been the mainstay of Guinea commerce; the search by both Africans and Europeans for a stable new relationship in the absence of slave trading; and the failure of the major African kingdoms to adjust to the new economic and social circumstances swiftly enough to withstand growing European pressures.

These three themes are closely interwoven in the course of events in Africa. It should be noted, however, that The the major decisions regarding the abolition of the slave abolition trade were taken outside Africa and were responses to of slavery economic and political changes and pressures in Europe and America. Many of the Christian churches had never accepted the morality of trading in human beings, and the 18th-century Evangelical movements in Protestant Europe led to open campaigning against the Atlantic slave trade and also against the institution of slavery itself. These things were equally condemned by new secular currents of thought associated with the French Revolution. Because plantation production in tropical America was no longer as profitable a field for investment by northern Europeans as industry, or as trade with other parts of the world, the propaganda against the slave trade began to take effect. Denmark outlawed slave trading by its citizens in 1803, Great Britain in 1807, the United States in 1808, Sweden in 1813, The Netherlands in 1814, and France (for the second time) in 1818.

The most significant of these actions against the slave trade was that of Britain. British ships had been by far the largest carriers of slaves at the end of the 18th century, and only Britain really possessed the naval resources necessary to secure enforcement of anti-slave-trade laws on the high seas. Furthermore, when Portugal, Spain, and some American countries expanded their slave trading to meet the deficiency caused by the British withdrawal, they met with strong opposition from Britain. The underlying reason for this was that Britain, more than any other European nation, had considerable amounts of capital, experience, and goodwill accumulated in trade with Africa. When British merchants tried to develop new lines in African trade to replace their old slave trade, however, they commonly found that, as long as their European or American rivals continued to buy slaves, African kings and merchants were generally not willing to organize alternative exports. Economic interest therefore combined with abstract morality to induce successive British governments to bring pressure on other governments to outlaw their slave trades and to permit the British navy to help enforce their laws on their ships at sea.

But these measures did not stop the export of slaves from Africa. Some nations, notably France and the United States, whose own naval controls were fitful, objected strongly to British warships stopping, searching, and, if need be, arresting their ships at sea. Furthermore, as long as there was a market for slaves in the Americas (i.e., until all the American countries had abolished the institution of slavery), there were lawless individual traders who felt that the profits to be gained from running slaves across the Atlantic more than outweighed the risk of arrest. Except when actually embarking slaves on the African coast or unloading them in American waters, the chances of interception at sea were in fact quite small. Although the British navy maintained in western African waters an anti-slave-trade squadron of up to 20 ships, which between 1825 and 1865 arrested 1,287 slave ships and liberated about 130,000 slaves, during the same period about 1.8 million African slaves are believed to have been landed in the Americas.

The final cessation of the export of slaves from Africa to the Americas took place toward the end of the 1860s. The decisive factor was the abolition of slavery in the United States in 1865. Slavery was then legal only in Cuba and Brazil—and only to the 1880s—and the risks of transporting slaves to these two markets became too high. Before this, British governments had already embarked on

a policy of taking or supporting active steps in Africa to stop slaves from being offered for sale on its coasts and to encourage the production of alternative exports. The immediate results of these efforts were often not very great. For example, many African governments and merchants were no more inclined than many European or American governments or merchants to enforce or to observe the anti-slave-trade treaties that British officials wished upon them. They saw no reason why their economic interests, which were bound up with slavery and trade in slaves, should be subordinated to the new economic interests of British traders following what was to them the capricious decision that slavery and the slave trade were wrong.

The British naval presence   What was significant was that Britain, through its desire to stop the export of slaves from western Africa and to protect the interests of British merchants desiring to trade in other commodities, maintained a substantial naval presence in western Africa and was also acquiring new political, commercial, and missionary presences. These led to increasing interference in the domestic affairs of African societies and their governments.

This interference began with the British naval squadron's need of shore stations to serve as bases for its patrolling ships and as landing places for the appreciable numbers of slaves it was intercepting. The slave ships had to be taken to a European jurisdiction to be condemned, and the slaves they had carried could not simply be returned to the societies that had sold them, but needed to be maintained as wards for whom Britain accepted political and moral responsibilities. British political officers and missionaries therefore became established on African soil, and the area of their activities was continually increasing. Explorers were penetrating the hinterland in search of new avenues for trade. British traders were competing with the slave traders. The liberated Africans were branching out into trade for themselves or simply returning home with new Western and Christian attitudes. All these were apt to ask for political or missionary support, and, behind this, naval action could be called upon if there were difficulties with the local African rulers.

For the greater part of the 19th century the prime centre for British naval, political, and missionary activities on the western African coast was Sierra Leone. Toward the end of the 18th century the Sierra Leone peninsula had been chosen by British philanthropists as a suitable place to which Africans who had been taken to Britain as slaves and freed there, or who had fought on the British side in the U.S. War of Independence, might be repatriated. A first group was sent out and settled on the site of the future Freetown in 1787. Although many of the early settlers did not survive, others were brought, and by 1811 Freetown had a liberated African population of about 2,000.

After a first false start, the philanthropists hoped to find funds for the maintenance of their settlement by placing it under the control of a company they had floated to trade with the interior. But the only trade that prospered in the Sierra Leone region was the slave trade, in which the company naturally did not engage, and after 1799, their colony, whose indeterminate constitutional status caused many difficulties, was able to survive only with the help of annual grants-in-aid from the British government. Eventually, in 1808, the British government agreed to take over direct responsibility for the colony from the Sierra Leone Company.

British coastal settlements   Freetown was not the only British settlement on the western African coast. Officials of a descendant of the old African Company of slave trading days still occupied a number of forts on the Gold Coast and one in the Gambia, and these were now meant to provide support for British merchants engaged in other trades. In 1817, after the settlements on the Sénégal, which had been in British hands during the Napoleonic Wars, had been handed back to France, a considerable number of British traders and their African associates moved to the mouth of the Gambia River and established there the new settlement of Bathurst (Banjul). Neither the Gambia nor the Gold Coast were exclusive British spheres, however. The French were strong competitors on the former, and both the Dutch and the Danes still held forts on the latter, and where European interests were divided, there was no certainty that the British settlements would prosper in competition with slave traders, nor that they could be developed as effective bases in an active campaign against that trade.

From 1808, however, British policy required that such a base be maintained in western Africa, and Freetown was the obvious choice. It had one of the best natural harbours on the coast, and it was already experienced in the resettlement of liberated slaves. Christian missions had begun to establish themselves there since 1806, and it became the seat of a British governor and of anti-slave-trade courts and the headquarters of the navy's western African squadron. During the next 60 years this squadron was to swell the population under British rule by landing some 60,000 men and women, from all over western Africa, whom it had taken from arrested slave ships. Freetown's only serious disadvantage was that it was at one end of the slave-exporting coast. In 1827, therefore, the British navy also began to use the island of Fernando Po in the Gulf of Guinea as an alternative base and freed-slave settlement. But this activity aroused the interest of the Spanish government, which had had a legal claim to the island since 1778, and in 1834 the settlement was abandoned.

From 1814 to 1824 the British governor and commander in chief at Freetown was Sir Charles M'Carthy, an active military man who thought that the most effective means of achieving Britain's aims in western Africa was to extend its formal dominion over the most vexatious outlets for the slave trade. The home government for a time countenanced this policy and in 1821 transferred the forts on the Gambia and Gold Coast to M'Carthy's administration. During the 10 years of his government its expenditure quadrupled to nearly $400,000 a year. There was no corresponding increase in British trade (nor any diminution of the slave trade), however, with the result that the cost had to be met by British taxpayers who were antagonistic to spending money on colonies. In 1824 M'Carthy's forward policy led him to make common cause with the Fanti against Asante claims to overlordship on the Gold Coast. In the war that followed, however, he was defeated and killed, and the British government decided that it should withdraw from all formal commitments in western Africa except at Sierra Leone.

In fact the most prosperous British trade was developing on a part of the coast on which there was no British interference other than naval action to intercept slave ships and to secure anti-slave-trade treaties. That was the Niger delta. British shipping had been paramount there when the British slave trade had been abolished in 1807, and the merchants of the delta city-states had quickly adapted themselves to offering palm oil as an alternative export to slaves.

Britain's Industrial Revolution had occasioned a growing demand for vegetable oils as lubricants and for the manufacture of soap, and the new Lancashire cotton industry was producing in quantity a commodity with which palm oil might readily be purchased. By the 1830s the British purchases of palm oil in western Africa were worth nearly $2 million a year. About nine-tenths of this trade was initially with the Niger delta. The oil palm grows throughout a belt just behind the western African coast, and the oil from its fruit was already widely consumed and traded locally. Africans of the delta were much quicker and more successful in developing an export trade in palm oil than were those of other coastal regions. One reason was simply that the oil was not easy to transport in quantity, and its value was not high in proportion to its bulk. Canoe transport was thus easier and cheaper than headloading or cask rolling, and the delta afforded a ready-made system of waterways. But its hinterland also had an unusually dense population in a relatively poor agricultural environment and therefore had both a greater need to exploit the semiwild palm trees than was usually the case and more labour with which to do this and to manufacture and transport the oil. Moreover, the collection of the fruit and the manufacture of the oil were traditional household activities, and to exploit these for export necessitated a commercial system that was both wide and intensive and, in addition, highly responsive and flexible.

British trade with the Niger delta

The small, highly competitive city-states of the Niger delta, built up and ruled by merchants, could exploit the overseas demand for palm oil much more quickly and efficiently than was possible elsewhere. In Liberia and western Côte d'Ivoire, for example, the trading network, like the population, was thin and little advanced. Elsewhere export trading (for example, in slaves or gold) had been directed, or at least controlled, by large-scale organizations that were less flexible, politically motivated, and much less responsive to commercial pressure; among these were the traditional political hierarchies of large kingdoms such as Benin, Asante, and Dahomey, or the new politico-religious administrations of the Fouta Djallon or of al-Ḥājj 'Umar. It may be noted, incidentally, that the successful development of palm-oil exports from Yorubaland followed upon the collapse of the Oyo empire there. It was not until about the 1860s, when the total British purchases of palm oil were worth about $6 million a year, that exports from the rest of western Africa, with Yorubaland in the vanguard, began to equal those of the Niger delta.

British official policy toward western Africa remained one of minimum intervention until the 1870s. Indeed, the view that Britain should withdraw from all commitments other than in Sierra Leone was most forcefully asserted by a Parliamentary Select Committee as late as 1865. In fact, however, both positive and negative results of the active British campaign against the Atlantic slave trade made it impossible for the policy of nonintervention to be maintained in practice.

The growth of the spirit of European scientific inquiry during the 18th and 19th centuries combined with a practical interest in finding out what Africa produced besides slaves that could be of value to world trade and what political, economic, and transport systems existed to permit such products to be brought down to the coast, to lead to a great movement of European exploration of the interior of western Africa between 1788 and 1855. This movement was primarily directed from Britain, and from 1805 the British government sponsored many of the major expeditions.

These explorations suggested a possible strategy of breaking through the barrier of the established slave-trading states at the coast by using the Niger River to trade directly with the interior. This seemed attractive after the rejection of the M'Carthy policy of positive coastal action, and from 1832 onward the British government sponsored or helped to sponsor a number of expeditions designed to develop navigation up the Niger. By 1854 quinine and the

steamship had solved the technical problems of navigating the lower river, but a new political problem had been created in the objections of both black and white traders in the delta to their established trading system being bypassed in this way.

By the middle of the century the development of the liberated African community in Sierra Leone under the tutelage of British administration, churches, and education meant that some of its members were providing a considerable reinforcement for the British interest in western Africa. Economic activities in Sierra Leone itself were limited, and Sierra Leoneans soon finding their way along the coast as independent pioneers of trade and Westernization or as auxiliaries to British traders, officials, and missionaries. Their most significant influence was in Yorubaland. By the 1840s at least half the liberated Africans were of Yoruba extraction, and by this time their homeland afforded considerable scope both for independent traders and for people seeking to introduce Christian and Western ideas and ways into African life. Both these circumstances derived from the failure of the Oyo empire in the 18th century to establish a stable form of central government capable of maintaining a firm control over the provinces it had conquered. There remained a dangerously uncertain balance of power between the king and the traditional chiefs of the capital.

Such a situation was by no means unique in the history of the kingdoms of Guinea (or, for that matter, of western Africa). Dahomey seems to have avoided it only because its kings, initiating their kingdom through the conquest of peoples who were not of their own stock, had been able to build up an unusually authoritarian form of government. But in both Benin and Asante traditional kinship organizations imposed restraints on royal authority, and tensions could develop when it came to sharing the rewards of empire and trade. There was a near disastrous civil war at Benin at the end of the 17th century, though the king emerged from it with his authority strengthened, apparently because he was able to play off the town chiefs against the chiefs of his palace. Asante had come into being as an alliance of petty kingdoms against Denkyera, and its kings, desiring to be more than merely primus inter pares, began by entrusting the new kingdom's conquests mainly to the chiefs of their capital, Kumasi. But the chiefs then sought to control the monarch, and the latter had to turn for help from the provincial rulers to release him from this situation. Ultimately, however, from the time of Osei Kojo (c. 1764–77), the kings secured their

European penetration into western Africa in the late 19th century.

preeminence throughout the kingdom by building up a new hierarchical military and civil administration, which was responsible uniquely to them and which limited the power of both sets of chiefs.

At Oyo the traditional town chiefs, who commanded the army of the capital, converted the kings into puppets during the 1750s and '60s. About 1774 they gave the throne to a king, Abiodun, who escaped from their control and used provincial forces to establish royal authority over the capital. After Abiodun's death (*c.* 1789), the provincial chiefs began to act with increasing independence. When (*c.* 1817) the viceroy of the north invited Fulani aid to help consolidate his rebellion, the result was not simply that the kings of Oyo lost their northern provinces to the Fulani; they also lost control over the northern trade routes on which they depended for their vital supplies of horses and slaves, and eventually (*c.* 1836) they had to evacuate their capital to the south. By this time there was no longer any central authority, and everywhere ambitious men were vying with each other to create personal dominions over as many clients and slaves as possible.

One consequence of this situation was a great increase in the number of slaves available for export from nearby Dahomey, which by 1818 had thrown off the last vestiges of Oyo suzerainty and was soon sending its armies deep into Yorubaland, and from independent traders at ports such as Lagos and Badagri. It was the close attention given by the British navy to these coasts that had led to the build-up of Yoruba former slaves in Sierra Leone. By the 1840s considerable numbers of these people were returning to Lagos and Badagri and, especially, the new inland town of Abeokuta, originally built up as a refuge where Egba (southern Yoruba) peoples could withstand pressures from Ibadan, the most powerful of the new Yoruba political units, and from Dahomey. The advent of the settlers from Sierra Leone soon brought British missionaries, and a new British-aligned influence was added to the tangled web of Yoruba politics.

The first British consulate

British officialdom soon followed. In 1848 a British consulate had been established for the Gulf of Guinea to maintain British interests in the complex situation arising from the splintered politics of the Niger delta and the beginnings of navigation on the river itself.

The consuls joined with naval officers in attempts to stop the king of Dahomey from exporting slaves, and, when repulsed, turned to Lagos, where they saw their opportunity in a split in the royal family. In 1851 the British navy restored to his throne a deposed monarch who had promised to stop the Lagos slave trade. He was in fact powerless to do this without continued British support. Lagos became the seat of a second British consulate in 1853, and in 1861 it was annexed. British and Sierra Leonean traders endeavouring to develop palm oil trade with Yorubaland were soon trying to persuade the colonial government at Lagos that only a further advance of its authority into the hinterland would stop its wars and its export of slaves and allow their own affairs to prosper.

The first serious advance of British power in western Africa occurred on the Gold Coast. After the withdrawal of British officials and troops in 1828, the British Gold Coast traders took on a young army officer, George Maclean, to represent their interests there. Maclean negotiated a peace with Asante and established an informal jurisdiction through the coastal states, which brought security for both British and Asante merchants. The consequent fourfold increase in British trade combined with the uncertain legal status of Maclean's jurisdiction to bring British officials back to the forts in 1843. In 1850 they took over the Danish forts also, but the continued Dutch presence on the coast prevented them from raising an effective revenue from customs duties, and they quarrelled with the coastal peoples over the issue of direct taxation. They therefore failed to erect an effective coastal administration of their own on the foundation laid by Maclean, and they equally rejected alternatives proffered by educated Africans in cooperation with the coastal chiefs. Trade declined, and Asante's armies began to invade the coastlands to protect its interests there. Eventually the Dutch were led to withdraw altogether (1872) and the British to invade Asante

and destroy its capital and to declare the whole coast a colony (1874).

Three-quarters of a century of turmoil following the British decision to campaign against the Atlantic slave trade and to foster the interests of legitimate trade and Christian civilization in western Africa had therefore resulted in the establishment of the new colony of Sierra Leone and direct British intervention in African affairs in much of the most prosperous area of the old trade— the Gold Coast, Lagos, and the delta and lower river of the Niger.

African sovereignty had also been infringed between Sierra Leone and the Ivory Coast where, inspired by the Sierra Leone example, private U.S organizations had settled freed slaves for whom there was no place in their own society prior to 1863. British and French merchants questioned the right of the settlers to control and to tax their trade and, since formal U.S. policy was anticolonial, the result, in 1847, was the proclamation of the Republic of Liberia. The settler government then embarked on a long struggle to assert control over the local Africans. Because, unlike a colonial government, it had no metropolitan resources or finance to help, this was a prolonged business.

The Republic of Liberia

The growth of British trade, and of British influence and power, in western Africa was by no means to the liking of the government, traders, and navy of France— Britain's principal competitors in the previous century. But France's mercantile interest in western Africa was not as strong as Britain's, and its traders there received less official and naval support than did the British. Not until the 1870s and the opening of the European scramble was any serious effort made to develop the trading footholds that were established on the coast between Senegal and Sierra Leone, on the Ivory Coast, and between the Gold Coast and Lagos.

France's main effort in western Africa was devoted to developing its old interests in Senegal following the British withdrawal in 1817. Initially an attempt was made to replace the former business of exporting labour to the West Indies by developing a local plantation economy. By the 1820s this was foundering, and matters then drifted until the arrival in 1854 of a new governor, Louis Faidherbe, a soldier with experience in the conquest of Algeria and in the government of its peoples. Faidherbe's concept was to secure control of the exports of the westernmost Sudan by extending French military and political control up the Sénégal River and to encourage local African production of the peanut (groundnut) to help meet the growing French and European demand for vegetable oils. By the time of his departure in 1865, Senegal had become the prototype for subsequent European colonization in western Africa and a springboard from which the French could think of conquering the whole Sudan.

Senegal as a colonial prototype

COLONIZATION

The European scramble to partition and occupy African territory is often treated as a peripheral aspect of the political and economic rivalries that developed between the new industrial nations in Europe itself and that were particularly acute from about 1870 to 1914. Its opening has commonly been taken to be either the French reaction to the British occupation of Egypt in 1882 or the Congo basin rivalry between agents of France and of Leopold II of the Belgians that led to the Berlin West Africa Conference of 1884–85, both of which are seen as being exploited by Bismarck for purposes of his European policy.

In western Africa, however, it seems fair to say that the beginnings of the scramble and partition were evident at least a generation before the 1880s and that they were determined by the local situation as much as or more than they were by European domestic rivalries. Already during 1854–74, the logic of the situation in western Africa had led France and Britain to take the political initiatives of creating formal European colonies in Senegal, in Lagos, and in the Gold Coast. All along the coast, in fact, the traditional African political order was becoming ineffective in the face of European economic and social pressures. For most of the 19th century these pressures had been predominantly British, but in the 1870s French compa-

nies began to offer effective competition to the British traders not only in Upper Guinea, where they had always been strong, but also on the Ivory Coast, in the ports immediately to the west of Lagos, and even in the lower river and delta of the Niger. An unstable situation was developing in which the European traders were likely to call for further intervention and support from their governments, and especially so if the terms of trade were to turn against them. Low world prices for primary produce during the depression years from the 1870s to the mid-1890s certainly caused difficulties for Europeans trading to western Africa and led them to think that an increase in European control there would enable them to secure its produce more cheaply.

The changing balance of power in western Africa was not confined to the coastlands. By the 1870s formal French and British armies had already ventured into the interior and had inflicted defeats on such major African powers as those of al-Ḥājj 'Umar and Asante. In 1879 Faidherbe's heirs on the Sénégal River had launched the thrust that was to take French arms conquering eastward across the Sudan to Lake Chad and beyond.

By the end of the 1870s France and Britain, therefore, were already on the march in western Africa. The principal effect of the new forces stemming from domestic power rivalries in Europe itself—the most dramatic of which was the appearance in 1884 of the German flag on the Togoland coast, between the Gold Coast and Dahomey, and in the Cameroons—was to intensify and to accelerate existing French and British tendencies to exert their political and military authority at the expense of traditional African rulers.

French incentives to expand There can be no question but that, by the end of the 1870s, the advance of the British interest in western Africa had been more rewarding than the advance of the French interest. Devoting their attention primarily to the active economies of the Niger delta, the Lagos hinterland, and the Gold Coast, British traders had secured $24 million of business a year, compared with the French merchants' trade of $8 million, three-quarters of which was concentrated on the Sénégal River. Initially, therefore, the French had much more incentive for expansion than the British.

Britain was already in political control of the Gold Coast, and the arrival of the German treaty makers in Togo and in the Cameroons in 1884 hastened it to declare its protectorate over most of the intervening coastline on which British traders were active. The gap left between Lagos and Togo was swiftly filled by the French, and from 1886 they also established formal authority over all other parts of the coastline that were not already claimed by the governments of Liberia, Portugal, or Britain. In this way the baselines were established from which France subsequently developed the colonies of Dahomey, the Ivory Coast, and French Guinea.

France's advance inland from these southern coasts was subsidiary, however, to the main thrust, which was eastward from the Sénégal region through the Sudan. The glamour of its past had persuaded the French that the Sudan was the most advanced, most populated, and most productive zone of western Africa. Once they had reached the upper Niger from the Sénégal (1879–83), the French forces had a highway permitting them further rapid advances. By 1896 they had linked up with the troops that had conquered Dahomey (1893–94) to threaten the lower Niger territories which British traders had penetrated from the delta.

The rapid French advance across western Africa from the Sénégal River had denied the British any chance of exploiting the commercial hinterland of the Gambia River and had severely restricted their opportunities from Sierra Leone. Government and mercantile interests nonetheless were able to agree on the need for British action to keep the French (and also the Germans from Togo and from the Cameroons) out of the hinterlands of the Gold Coast, Lagos, and the Niger delta. Asante submitted to an ultimatum in 1896 (the real war of conquest was delayed until 1900–01, when the British had to suppress a widespread rebellion against their authority), and a British protectorate was extended northward to the limits of Asante influence.

On the Niger, British interests were first maintained by an amalgamation of trading companies formed in 1879 by Sir George Goldie to combat French commercial competition. In 1897 the British government agreed to support Goldie's Royal Niger Company in the development of military forces. Three years later, however, it recognized the foolishness of allowing the company's servants and soldiers to compete for African territory with French government officials and troops and to enforce its monopolistic policies on all other traders within its sphere. The company was divested of its political role, and the British government itself took over direct responsibility for the conquest of most of the Sokoto empire. Thus, although the French eventually reached Lake Chad, they were kept to the southern edges of the Sahara, and most of the well-populated Hausa agricultural territory became the British protectorate of Northern Nigeria. In 1914 this was merged with the Yoruba territories, which had been entered from Lagos during the 1890s, and with the protectorate over the Niger delta region to constitute a single Colony and Protectorate of Nigeria. From company territory to protectorate

As early as 1898 Europeans had staked out colonies over all western Africa except for some 40,000 square miles of territory left to the Republic of Liberia. Portugal had taken virtually no active part in the scramble, and its once extensive influence was now confined within the 14,000 square miles that became the colony of Portuguese Guinea. Germany, the latecomer, had claimed the 33,000 square miles of Togo (together with the much larger Cameroon territory on the eastern borders of what is usually accepted as western Africa). France and Britain remained, as before, the main imperial powers.

France claimed by far the larger amount of territory, nearly 1.8 million square miles compared with some 450,-000 square miles in the four enclaves secured by Britain. In other terms, however, France had done less well. Its territory included a large part of the Sahara, and the three inland colonies of French Sudan (modern Mali), Upper Volta (modern Burkina Faso), and Niger were by and large scantily populated and, because of their remoteness from the coast, were contributing little or nothing to the world economy. In 1897 the trade of the four British colonies was worth about $24 million, compared with about $14 million for the seven French territories, and their combined population of more than 20 million was more than twice as great.

The political boundaries established by the Europeans by 1898 (though usually not surveyed or demarcated on the ground until much later) largely determine the political map of western Africa today. The only subsequent change of significance followed the British and French conquests of the German colonies during World War I (1914–18). While the larger parts of both Togo and Cameroon were entrusted by the League of Nations to the French to administer as separate colonies, in each case a smaller western part was entrusted to Britain to be administered together with the Gold Coast and Nigeria respectively. Ultimately British Togo chose to join with the Gold Coast and so became part of the new independent Ghana. The northern part of British Cameroon similarly joined with Nigeria, but the southern part chose instead to federate with the former French Cameroon.

If 20 years had sufficed for the European powers to partition western African lands, at least a further 20 years were needed to establish colonial regimes that were effective throughout all the vast territories claimed by Europe and that were accepted by all the Africans involved. The first problem was a military one.

Small and mobile columns of African soldiers, led and trained by European officers and noncommissioned officers and equipped with precision rifles, machine guns, and artillery, rarely experienced much difficulty in defeating the great empires created by the 19th-century jihadists. These chose to meet the invaders in pitched battles in which their massed feudal levies, with few modern weapons and limited skill in their use, served only as targets for the superior firepower and discipline of their opponents. Once these battles had been lost, the surviving leaders were usually ready to acknowledge the Europeans Feudal levies versus modern technological warfare

as new overlords. The main problems were really ones of distance and logistics. Thus it was not until 1900–03 that Sir Frederick Lugard's forces were sufficiently established in northern Nigeria to defeat the Sokoto Fulani, while the French "pacification" of the even more remote territory further north, which eventually became their colony of Niger, was not really completed until the 1920s.

A much more serious military problem was often presented by smaller political units, which were ethnically more homogeneous and often more densely populated than the jihad empires. Their subjugation was often a protracted business in which the Europeans had to fight virtually for each settlement. This was the case with the British campaign against Asante in 1900–01, with the subjugation of the Sierra Leone protectorate in 1898–99, and above all, perhaps, with the advance of British power into the densely populated Igbo and Tiv territories, which was hardly complete until as late as 1918. Similarly, the most formidable resistance faced by the French came not from the Tukolor, but from the more southerly empire established from the 1860s onward from the hinterland of Sierra Leone to western Gonja by the Mande leader Samory Touré. Though Samory was a Muslim whose activities did much to consolidate the hold of Islām in his territories, he was not a cleric like Usman dan Fodio or al-Ḥājj 'Umar. He came from a family of Dyula traders and soldiers, and the principles of his government recalled those of ancient Mali rather than of the jihad empires. Samory established his network of military and political control over territories long subject to Mande commercial penetration and settlement, and a number of campaigns had to be fought against him until he was finally captured and exiled by the French in 1898.

Once the superior firepower and organization of the Europeans had secured their military supremacy, they were faced with an even larger problem; namely, how the small forces they commanded were to maintain a permanent occupation and effective control over the vast territories they had overrun. Lugard, for instance, had conquered the Sokoto empire with only about 3,000 soldiers, only 150 of whom were Europeans, and to administer his northern Nigerian colony of some 250,000 square miles and 10 million people he had a civil establishment of only 200 Europeans. This kind of situation persisted almost throughout the colonial period. At the end of the 1930s, for example, the European establishment available to the British governor of the Gold Coast to control nearly four million people were only 842. It is obvious, then, that the conquerors were often very slow to extend effective rule throughout their empires, and particularly to those parts of them that were most remote, presented serious political problems, or seemed least profitable.

Initial difficulty of administration
No European control could be exercised without the cooperation of large numbers of Africans. This was secured in two ways. First, just as the Europeans had relied on Africans for the rank and file of their armies and police, so their administrations and economic enterprises could not function without a host of Africans employed as clerks, messengers, craftsmen of all kinds, and labourers. All of this employment offered new opportunities to Africans, and to ensure an efficient labour force all European administrations began to supplement and develop the schools begun by the missionaries.

As well as recruiting and training large numbers of Africans as auxiliaries in all spheres of European activity, the colonial powers also came to rely on African chiefs as essential intermediaries in the chain of authority between the colonial governments and their subjects at large. Both the French and the British colonial regimes were essentially hierarchical. The administration of each colony was entrusted to a governor who was responsible to a colonial minister in the government in Europe (in the French case, via a governor-general at Dakar). These governors were assisted by senior officials and a secretariat in the colonial capital, and their decisions and orders were transmitted for implementation to provincial and district commissioners. A district officer, however, could not deal directly with each of the tens, or even hundreds, of thousands of Africans in his care. He therefore gave orders either to the

traditional chiefs or to Africans who had been recognized as local rulers by his government, and these intermediaries passed them on to the people at large.

In this connection a difference of theory began to be discernible between French and British policy. The French regarded the local African chiefs as the lowest elements in a single administrative machine. This administration was to be conducted on entirely French lines. The British, on the other hand, came to believe more and more in "indirect rule." British authority was not to reach directly down to each individual African subject. While the British retained overall control of a colony's administration, it was to be made effective at the district level by cultivating and by molding the governments of the traditional African rulers.

The policy of indirect rule

Indirect rule was neither a new nor a specifically British expedient. Maclean had been an indirect ruler on the Gold Coast in the 1830s; Goldie had proposed indirect rule for the empire his Royal Niger Company had hoped to conquer; and, in the early days of their expansion, the French had often had no alternative but to seek to control their newly won territories through the agency of the African governments they had conquered. Once they were firmly established, however, the French almost invariably moved away from the practice. The British, on the other hand, evolved a theory of indirect rule that they tried to apply systematically to their colonies during the first half of the 20th century. This was largely due to the influence of Lugard. In 1900–06 he had seen no other way to control the vast population in northern Nigeria, whose rulers he had defeated, and he had subsequently been promoted governor-general (1912–19) of a united Nigeria, which was by far the most important British colony in Africa. After his retirement to Britain, he became a dominating influence on the formation of colonial administrative policy, so that indirect rule became accepted as the ideal philosophy of government for British tropical Africa.

Not all areas of western Africa were as suitable for Lugardian indirect rule as northern Nigeria. Lugard himself experienced considerable problems in trying to apply it to the largely chiefless societies of eastern Nigeria and to the Yoruba of the southwest, where authority and law were not as clear-cut. In the Gold Coast indirect rule proved more acceptable to the Asante than the direct rule imposed after the conquest of 1900–01. Farther south, however, the Western-style economy and modes of thought had made such inroads that there were endless problems in the implementation of indirect rule, and the full constitutional apparatus for it was hardly installed until the 1940s.

The development of indirect rule also implied a contradiction with an earlier tradition of British colonial government, that of the colonial legislative council. The governors of British colonies were allowed more initiative than French governors and were supposed to exercise this in the interests of their individual territories insofar as these did not contradict the overriding British interest. To help them in this, each colony was equipped with a legislative council that included representatives of local opinion, and this council's consent was normally required before laws were enacted or the colonial government's budget was approved.

The institution of the legislative council had evolved from experience with settler colonies outside Africa; when such councils were introduced into tropical Africa from the 1840s onward, most of their members were colonial officials. A minority of "unofficial" members represented trade and the professions rather than the traditional communities, and these were not elected but were nominated by the governor. However, 19th-century colonial officials, traders, and professionals were almost as likely to be black as white, and the early legislative councils were by no means ineffective vehicles for the expression of African interests and of criticisms of British policy. It was thus possible both for the British and for the educated African elite in their colonies to view the legislative councils as embryo parliaments that would eventually become composed of elected African members who would control the executive governments, which would themselves, through the growth of education in the colonies, become more and more composed of African officials.

The legislative councils as embryo parliaments

Although very little thought was given to the matter, because it was supposed that the development might take centuries, it was supposed that the British colonies in Africa would follow the example of Canada and Australia and ultimately emerge as self-governing members of the empire. The equally remote future for the French colonies, on the other hand, was thought to be the acculturation (*assimilation*) of their people, so that ultimately they would all become full French citizens, the colonies would be integrated with metropolitan France, and the African citizens would share equally with the French-born in its institutions.

Both of these ideals were more appropriate to the colonial situations in western Africa before the great scramble for territory that began in 1879, when the colonies were comparatively small territories in which European influence had been slowly but steadily gaining ground for a considerable period. They were effectively shelved when it came to grappling with the problem of governing the enormously greater numbers of Africans without any real previous contacts with European ways who were quickly brought under colonial rule in the years after 1879. Thus, on the French side, though those born in the four major communes (Saint-Louis, Gorée, Rufisque, and Dakar) of the old colony of Senegal continued to enjoy the French citizenship that they had been granted prior to 1879, other Africans became French subjects (possessing the obligations of citizens but not their rights), who could only qualify for citizenship after stringent tests. By 1937, out of an estimated 15 million people under French rule in western Africa, only some 80,500 were citizens, and only 2,500 of these had acquired their citizenship by means other than the accident of birth in one of the four communes.

In the British colonies, however, where the legislative councils were already a reality, there was a dichotomy between them and the institution of indirect rule. Initially, insofar as this was resolved at all, it was at the expense of the development of the legislative councils. Thus the competence of the council in the Gold Coast was not extended to Asante before 1946, while in Nigeria until 1922 the council's competence was restricted to the small territory of Lagos. It was not until 1922 that any elected members appeared in the councils, and they remained for a generation a small proportion of the total unofficial membership, chosen only by tiny electorates in a few coastal towns. For the rest, the African population remained firmly under British control through the mechanism of indirect rule. The implication was not only that the norms of African society and political behaviour were far removed from those of western Europe but also that the British had by no means accepted that African society and politics would or should evolve in that direction. Those few Africans who had become educated and acculturated in Western ways were not thought to be representative of the mass. There was a move to exclude local Africans from the colonial administration, which became regarded as a professional service, liable to serve anywhere in Africa, with the role of holding the ring until, in some unexplained fashion, the native administrations under indirect rule had developed sufficiently to make British control superfluous.

Colonial rule. In fact, of course, the very existence of colonial rule meant that the fabric of African societies was exposed to alien forces of change of an intensity and on a scale unparalleled in the previous history of western Africa. Hitherto remote territories like Niger and Mauritania, where there had been very little change since the introduction of Islām, were from about 1900 suddenly caught up in the same tide of aggressive material changes that had for some time been affecting the coastal societies in Senegal or in the southern Gold Coast and Nigeria. From the African point of view, there was little to choose between the European colonial powers. Portugal, despite the fact that it was virtually bankrupt at the onset of the colonial period, was as significant a bringer of change as France, Germany, and Britain. In fact, in the long run, a strange combination of its poverty with memories of its older colonial tradition were to make Portugal's sense of a *mission civilisatrice* even more pervasive than that of its stronger rivals.

Liberia's formal status as an independent republic did not mean that the forces of change associated with the colonial period were excluded from its territory. Its Afro-American ruling elite were orphaned members of a very rapidly changing Western society, who felt it essential to impose its ethos on black Africa. While colonial administrators often had a narrow, 19th-century concept of government as an arbiter, rather than as an active protagonist of change, the Liberians felt a need actively to enlist the support of Western capital and enterprise if they were to consolidate their rule over African peoples and to maintain the independence of their republic.

Up to 1912 the inexperience and relative weakness of Liberia's ruling elite meant that it achieved little except to run up a dangerous indebtedness to ingenuous and potentially rapacious European investors. In 1925–26, however, the tide began to turn for them when the American Firestone Tire & Rubber Company, worried lest its supplies of raw material should become a British colonial monopoly, secured a new American loan for Liberia and began to operate a one-million-acre plantation concession in the hinterland of Monrovia. The country was now supplied with a sure access to world trade, and its government with the means to achieve a stable revenue. Within 25 years Liberia's foreign trade grew from less than $3 million a year to some $45 million, and government revenue from a mere $500,000 a year to nearly $10 million. The evident dangers that Liberia might become too dependent on a single export crop, and that it and its administration might become sole fiefs of the American company, began to disappear when during World War II U.S. strategic interests caused its government to begin to give aid to Liberia and to develop its first modern port, and when in the 1950s both American and European interests began to exploit Liberia's large-scale deposits of high-grade iron ore. By the 1960s Liberia was on the way to becoming one of the richer western African countries, and the ruling elite began to feel sufficiently secure to share both some of its political power and some of its prosperity with the native peoples.

A cardinal rule for all colonial administrations in Africa before the 1930s was that colonies ought not to be a financial burden on the metropolitan governments and their taxpayers: the cost of colonial administration and development should be covered by the local revenues they could raise. So long as such a doctrine was maintained, it was impossible for any but the richest colonial administrations to devise coherent plans for the economic development of their territories; indeed, prior to the 1940s, the colonial government of the Gold Coast was virtually unique in putting forward such a plan, and then only in the 1920s, which were by and large exceptionally prosperous years.

The principal sources of revenue were (1) duties on trade entering and leaving the territory and (2) direct taxation (usually a poll tax or hut tax). But only those coastal colonies that had already entered the world economy prior to about 1880 had much in the way of trade on which customs duties might be levied or a sufficient internal production of commodities and circulation of money to produce any significant income from direct taxation. Other territories—such as British northern Nigeria, or the French colonies of the Sudan (Mali) and Niger—could not really provide enough revenue to support even the most essential administrative services, such as policing or—for that matter—tax gathering. For some time, therefore, these administrations were in receipt of grants-in-aid from some central source, and it was an attempt to shift this burden from metropolitan resources that as much as anything led the French in 1895 to bring together their western African colonies under a government general and that led Lugard to argue for the unification of the Nigerian colonies, which he eventually achieved in 1912–14. In each case it seemed advisable to use some of the comparatively buoyant revenues of the coastal territories to subsidize the administrations of those in the interior.

It was obvious enough that what was needed was to increase the European commercial penetration of western Africa. But only the prospect of the most lucrative prizes could induce private European investors to place substan-

[margin note left: The colonialists as harbingers of material change]

[margin note right: Sources of revenue]

tial amounts of capital in Africa in advance of adequate European administrations that could guarantee the safety and security of their investments and in advance of the economic infrastructures that would ensure their efficient deployment. The only lure that really operated to attract European investment in advance of the provision of such services was the prospect of rich mineral deposits. The greater part of western Africa's mineral wealth lies in ores such as those of iron, aluminum, and manganese, which are extremely bulky in relation to their value and require very large investments in transport and other facilities before they can be economically worked, and for which there was relatively little overseas demand before the 1930s. The possibilities of diamond mining in Sierra Leone and the Gold Coast were not really recognized until the 1930s.

Early investment incentives

In effect then, it was only the gold of the Gold Coast and Asante forests and, to a lesser extent, the tin of the Bauchi plateau in central Nigeria, that attracted the early attention of European investors.

Modern methods of gold mining first began to be employed on the Gold Coast as early as 1878, but the industry could not make much headway before 1902. By that time the colonial government had taken the decisive steps of defeating Asante, beginning to build a railway system, and establishing an effective civil administration in the relevant areas, which could ensure proper land surveys and some means of controlling and adjudicating disputes over the ownership of land and the validity of concessions of it. Bauchi tin mining began much later, in 1903, but similar, if less acute, difficulties prevented much progress before 1914.

Despite their poverty, and despite the risk of saddling the home governments and taxpayers with unwanted expenditure, colonial governments found that there was no alternative to their providing the basic infrastructures needed by the vast territories they claimed to rule. It was impossible to wait for private European enterprise to provide railways, harbours, telegraph lines, roads, medical services, schools, and all the other things that were needed to support an effective government, let alone to provide some possibility of economic growth sufficient to pay for better government.

French territories.   The problems facing the French were much more formidable than those facing the British. The British colonies were essentially based on territories close to the sea, in which European trade had been long established and whose African peoples were already accustomed to producing for the world market. The French had such a colony in Senegal, but from this they had expanded over vast, remote, and thinly populated territories that required very considerable investment before they could be efficiently administered or developed. By and large the French public had appreciably less capital to invest overseas than the British public had. By 1936 it was estimated that, whereas the British colonies in western Africa had attracted about $560 million of capital, the total outside investment in French West Africa amounted only to some $155 million.

French strategy was initially to open up and develop its western African empire from a base in Senegal on the same Sénégal–Niger river axis along which it had been conquered. As early as 1882 work was begun on a railway to link the heads of navigation of the two rivers at Kayes and at Bamako (which became the capital of the French Sudan). But this line was not completed until 1906, by which time it had become evident that Saint-Louis, at the mouth of the Sénégal River, was not capable of development into a modern port, and that the Sénégal was really suitable for navigation for only three months in the year. So first a railway was completed from Saint-Louis to the new harbour of Dakar in the lee of Cape Verde (1885), and then during 1907–24 a line was built directly from Dakar (since 1902 the federal capital for French West Africa) to Kayes to bypass the Sénégal River altogether.

The construction of an effective west–east transport system from the coast to the upper Niger thus took some 42 years to complete, and the only part of it that was profitable was that serving the peanut-growing areas of Senegal. There was a lag of some 20 years after 1924 be-

fore the thinly populated and impoverished French Sudan could respond to the stimulus of its improved communications with the outside world. Indeed the only major crop developed for the world market that could withstand the high costs of transport to the coast—over some 700 miles of railway—was cotton, and that only after considerable further investment in irrigation. Ultimately the main economic role of the Sudan was to provide foodstuffs for Senegal, whose peasant farmers found it more profitable to concentrate on growing peanuts for export.

Changes in French economic strategy

By 1914 French economic strategy had shifted from the concept of opening up the inland territories of the French Sudan, Upper Volta, and Niger, to the encouragement of agricultural production in the coastal colonies. To a limited extent, the way was pioneered by European plantations, more especially perhaps in the Ivory Coast. Generally these colonies were made remunerative by administrative pressures to induce African farmers to produce for export. Ultimately, just as the economy of the Senegal had become largely dependent on the export of peanuts, so that French Guinea became dependent on bananas (though at the very end of the colonial period, European and American capital began the successful exploitation of considerable deposits of bauxite and iron ore), and the economies of Dahomey and of Togo (after its conquest from Germany) became dependent on palm produce. The most dramatic successes were achieved in the Ivory Coast, where considerable exports were developed of coffee, cocoa, bananas, and lumber. Railways were built from suitable points on the coast to facilitate the export of these crops.

In the 45 years from 1912–13 to 1956–57, the French had boosted the foreign trade of their western African empire from about $58 million a year to about $600 million a year, with the result that the revenues available to their colonial administrations increased from about $8.5 million a year to as much as $315 million. (These figures exclude the part of Togo that was incorporated in the French empire only after 1914–18, and the trade and revenue of which by the mid-1950s were worth some $24 million and $4 million a year respectively.) In absolute terms in relation to the total population, which in the same period is thought to have doubled to an estimated 19 million, the results were not so spectacular; in 1956–57 foreign trade per capita overall amounted to about $32 and government revenue to about $17. The significance of the figures is also obscured by the federal system to which all the colonies except Togo were subject and which was deliberately used to enable the richer colonies to help the poorer. The trade and revenue figures cannot be easily broken down between the individual colonies. Whereas the estimated gross national products (GNPs) for Senegal and the Ivory Coast were in the order of $180 and $160 per capita respectively (the former considerably inflated by the colony's possession of the federal capital), only Togo (about $73) and French Guinea and Sudan (about $58 and $53, respectively) were thought to have GNPs per capita higher than $40.

British territories.   Each of the four British colonies must necessarily be treated as an independent unit, as each was so treated in British policy. The Gambia was merely a strip of land, averaging only seven miles in width, on either side of 292 miles of navigable waterway penetrating into what otherwise was French Senegal. Even in the 1950s its population did not exceed 300,000, and the possibilities for any sort of development were limited. In fact the colony achieved a fair degree of prosperity by concentrating on the production of peanuts, grown in part by farmers who migrated annually from Senegal for the purpose. By 1956–57 foreign trade was some $60 per capita and government revenue $14.

The Sierra Leone situation was one of a relatively dense population exploiting or even overexploiting a poor environment for its subsistence, and initially the most that was achieved was to develop some palm produce for export. During the 1930s the situation began to change when European companies began to exploit extensive diamond-bearing gravels and to mine high-grade iron ore. By the mid-1950s foreign trade, which had been $14 million ($9

per capita) in 1913–14, had risen to $101 million ($44). About half of this was based on the activities of the foreign-owned mining companies. These provided little local employment; and furthermore, large numbers of people had been led to abandon farming to dig for diamonds on their own account. This gave rise to numerous social, economic, and political problems, because legally the diamond-bearing grounds had been conceded to the European companies. These factors may explain why the increase in government revenue, and hence the capacity of the government to sponsor further development, was low in comparison with other western African territories. It rose from $3.6 million ($2.40 per capita) in 1913–14 to $27 million ($11.70) in 1956–57, a factor of increase of 4.9, which compares unfavourably with a factor of 21.1 for French West Africa as a whole, 11.4 for the Gold Coast, 6.1 for Nigeria, or even 5.9 for the Gambia.

Com- | parative | increases | in revenue (margin note, left)

The Gold Coast was a complete contrast, indeed one of the most successful examples of colonial development anywhere in British tropical Africa. The people of its coastlands were long accustomed to world trade, and indeed to British rule, with the result that the Gold Coast entered the colonial period with a very high level of economic activity. In 1912–13 its foreign trade was worth $42.5 million ($28.30 per capita) while government revenue was $6.5 million ($4.30 per capita). Subsequent development was facilitated by the possession, within a manageable area that was adequately but not too densely populated, of a considerable variety of resources.

The first railway was built inland from Sekondi in the southeastern Gold Coast between 1898 and 1903 with the dual purpose of supporting gold mining and ensuring political control of Asante. This railway subsequently was used for the removal of manganese ore and bauxite. Extensive diamond diggings, worked equally by individual Africans and by European companies, began to be developed from 1919 onward. But the mainstay of the economy became cocoa, which local farmers began to produce on small plots in the forest toward the end of the 19th century. They found a reliable market for their produce. Cocoa became the most valuable export when it outranked gold in 1913, and thereafter went on to contribute more than four-fifths of exports and to constitute something between a third and a half of the world's supply.

The prosperity derived from cocoa in the 1920s enabled the governor, Sir Frederick Gordon Guggisberg, to pledge the country's revenues for loans to finance a coherent program of economic and social development. The Gold Coast's first deep-water port was built at Takoradi, the cocoa-producing forestlands were equipped with a comprehensive railway and road system, and the foundations were laid for educational and medical services as good as any in tropical Africa. Subsequent development was severely checked by the Great Depression of the 1930s and by events of World War II, but by the mid-1950s the postwar demand for tropical produce generated trade for the Gold Coast, estimated to have fewer than five million people, of about $500 million a year, not far short of that generated by all the 19 million people living in French West Africa. Government revenue reached the high level of $27.50 per person, by far the highest in western Africa, while the GNP of about $200 per person was probably higher than that of any tropical African country.

Nigeria provides yet another contrast. The people of its southern territories, like those of the southern Gold Coast or of Senegal, had long been in touch with the world economy. In 1912–13 the country's trade, at some $65 million a year, was 50 percent higher than the Gold Coast's and greater even than the combined total for the eight French colonies, including Senegal. But Nigeria was a giant territory, three times as large as the other three British colonies put together, and though compared with the French federation it was relatively small and compact (373,000 square miles), it had the same problem of extending over a considerable area of the remote western Sudan. This could not be ignored—as the much smaller northern Gold Coast or such northern French colonies as Niger were effectively ignored—because the Nigerian Sudan contained more than half the country's enormous population.

By the mid-1950s the Nigerian population was more than 32 million, more than half that of western Africa.

Two things were clearly needed: first, to develop a transport system to make it possible to control and open up the populous north; and, second, to use some of the wealth generated from the growth of foreign trade in the south to stimulate development in the north. No coherent policy was possible, however, before the amalgamation of the separate colonial administrations, which was achieved under Lugard in 1912–14. Initially, even railway building tended to provoke disunion. The first line was built inland from Lagos in 1898–1901 to open up Yorubaland. Before this line was extended to the north across the Niger, the northern government had begun its own railway, from the highest point of navigation on the river, through its new administrative capital of Kaduna, to Kano. In 1912 this was intercepted by an extension of the Lagos line, and subsequently branches were built to areas active in tin mining and the cultivation of peanuts. Finally, another line was built from a new eastern port, Port Harcourt, to the coal mines around Enugu (1916), and this was subsequently extended to Kaduna (1927). By the 1930s Nigeria had 1,900 miles of railway, nearly as many as those possessed by all the French territories together (2,160 miles) but built at nearly twice the cost.

While southern Nigerian development, based essentially on cocoa production in the west and processing of palm oil and kernels in the east, followed much the same pattern as that of the southern Gold Coast, and with essentially similar social consequences, the development of peanuts as the prime export crop of the north did not produce comparable results for its appreciably larger population. By the mid-1950s the trade of Nigeria, at some $800 million a year, was still greater than that of all French West Africa in total, but it was appreciably less per capita, $25.30 compared with $32.20, and the annual revenue available to government, at $173 million, was small in proportion to the total population, only about $5.50 per capita. Inevitably a serious gap had developed between the economic and social progress of the south and that of the north.

Nigerian | trade (margin note, right)

DECOLONIZATION AND THE REGAINING OF INDEPENDENCE

The end of the colonial period and the establishment during 1957–76 of all the former colonies as independent states was attributable both to a change in European attitudes toward Africa and the possession of colonies and to an African reaction to colonial rule born of the economic and social changes it had produced.

Europeans had colonized western Africa in the later 19th and early 20th centuries confident that their civilization was immensely superior to anything Africa had produced or could produce. Yet hardly had their colonies been established than these convictions began to be challenged. World War I, and the immense misery and loss of life it caused, led some Europeans to doubt whether nations who could so brutally mismanage their own affairs had any moral right to dictate to other peoples. Some reflection of this view was seen in the League of Nations and the system of mandates applied to the former German colonies. Although in western Africa these were entrusted to either French or British administration, the mandated territories did not become the absolute possessions of the conquerors, and the role of the new rulers was declared to be to equip the mandated territories and their peoples for self-government.

A second shock to European self-confidence came with the Great Depression of the 1930s, when trade and production shrank and millions of Europeans had no work. It began to be argued that a remedy lay in more active development of the overseas territories controlled by Europe. If more European capital and skills were directed to the colonies, so that they could produce more raw materials for European industry more efficiently, both Europe and the colonies would gain; as the colonies became wealthier through the exploitation of their resources, the people of the colonies would buy more from Europe.

In 1929 Britain had enacted the first Colonial Development Act, providing that small amounts of British

First
Colonial
Develop-
ment Act

government money could be used for colonial economic development, thus breaking the deadlock by which the only colonial governments that could embark on development programs to increase the wealth of their subjects, and to improve their own revenues, were those that already commanded sufficient revenue to pay for the programs or to service the loans the programs required. The idea that the colonies should be actively developed, in the European as much as in the African interest, was broadened during and after World War II. Transport and currency problems made it urgent for Britain and France to exploit strategic raw materials in their colonies. Furthermore, during 1940–44, when France itself was in German hands, it was only from the colonies and with their resources that General Charles de Gaulle and his associates could continue the fight.

The British funding policy, initiated in 1929, of providing the funds needed for colonial development was greatly expanded in the 1940s and extended to social as well as economic plans. After the war the governments of both Britain and France required their colonial administrations to draw up comprehensive development plans and in effect offered to provide the funds for those that could not be funded from local resources.

In view of past history, the need for such plans was probably greater in the French colonies than in the British, and the French West African program for 1946–55 envisaged the investment of $1,108,000,000, compared with programs totaling $549 million for the four British colonies. Virtually all of the financing for the French program came from France itself. But some of the British colonies had built up considerable reserves from the high prices commanded by their produce during the war and immediate postwar years, and they themselves were able to provide much of the money needed. This tended to accentuate already existing disparities. In the extreme case the Gold Coast plan envisaged spending $300 million, only 4 percent of which was British money. This was the same level of expenditure, roughly $60 per capita, as envisaged for French West Africa. Nigeria's program, with a contribution from Britain of 42 percent, proposed to spend $220 million—only about $7 per capita. The figures for Sierra Leone were $21 million, 45 percent from the United Kingdom, and $10 per capita; and for the tiny Gambia $8 million, 35 percent, and $27 per capita.

The accompanying political changes were more cautious and turned out to be inadequate to accommodate African aspirations—which had been derived from social changes occasioned during the classical period of colonial rule and further whetted by the policies of active economic development. On the British side, during 1945–48 the legislative councils were reformed so that African representatives outnumbered the European officials. Many of these African members, however, were still government nominees, and, because of the British attachment to indirect rule, those who were elected were mainly representative of the traditional chiefs.

Political advance for the French colonies was naturally seen in terms of increased African participation in French political life. In 1944 it was proposed that the colonies become overseas territories of France. Delegates from the colonies in fact participated in the making of the new postwar French constitution, but this was subject to referenda in which metropolitan French votes predominated. The constitution eventually adopted in 1946 was less liberal to Africans than they had been led to expect.

The emergence of African leaders. By the later 1940s, however, there were appreciable numbers of Africans in both the French and the British colonies who had emerged from traditional society through the new opportunities for economic advancement and education. In coastal areas Christian missionaries and their schools had advanced with the European administrations. The colonial governments, requiring African subordinates for their system, commonly aided and developed the elementary and vocational education initiated by the Christian missions and often themselves provided some sort of higher education for the chiefly classes whose cooperation they required. If rather little of this education had penetrated to the Sudan

Gold Coast
develop-
ment

by the 1940s, in some coastal areas Africans had become eager to invest some of their increasing wealth in education, which was seen as the key to European strength.

Relatively few Africans started up the French educational ladder—school attendance by the mid-1950s was some 340,000, about 1.7 percent of the total population—but those who did found themselves in a system identical with that in France. In British West Africa schools had got a footing before there was much administration to control them, and their subsequent development was more independent. The British educational system therefore developed into a pyramid with a much broader base than the French one. By the mid-1950s there were more than two million schoolchildren in Nigeria, about 6 percent of the total population and a much higher proportion of the population of the south, in which the schools were concentrated; in the Gold Coast there were nearly 600,000, some 12 percent of the population. Many more people in the British than in the French territories thus got some education, and appreciably more were able to attend universities. In 1948 universities were established in the Gold Coast and Nigeria; by 1960 the former territory had about 4,500 university graduates and the latter more than 5,000. The first French African university was a federal institution at Dakar opened in 1950; by 1960 the total number of graduates in French West Africa was about 1,800.

Univer-
sities

By the 1940s there was enough education to make European-style political activity possible in all the coastal colonies. Such activity may be traced back to at least the 1890s, when Gold Coast professionals and some chiefs founded the Aborigines' Rights Protection Society (ARPS) to prevent the wholesale expropriation of African lands by European entrepreneurs or officials. The ARPS went on to campaign against the exclusion of qualified Africans from the colonial administration. Following this, in 1918–20, a National Congress of British West Africa was formed by professionals to press for the development of the legislative councils in all the British colonies into elective assemblies controlling the colonial administrations.

In French West Africa early political activity was concentrated in the four towns of Senegal whose people possessed political rights before 1946. Because the seat of power was very clearly in France, with Senegalese electors sending a deputy to the French National Assembly, the result by the 1930s was the emergence of a Senegalese Socialist party allied to the Socialists in France.

By the late 1940s both the French and the British territories possessed an educated, politicized class, which felt frustrated in its legitimate expectations; it had made no appreciable progress in securing any real participation in the system of political control. In fact, anything approaching effective African participation seemed more remote than ever. Implementation of the development programs led to a noticeable increase in the number of Europeans employed by the colonial regimes and their associated economic enterprises. On the other hand, because many Africans had served with, and received educational and technical training with, the British and French armies, the war had led to a great widening of both African experience and skills. Furthermore, the postwar economic situation was one in which African farmers were receiving high prices for their produce but could find little to spend their money on, and in which the eagerly awaited development plans were slow to mature because European capital goods were in short supply.

An
African
elite

The formation of African independence movements. There thus developed a general feeling among the intelligentsia that the colonies were being deliberately exploited by ever more firmly entrenched European political and economic systems and that there had developed a new, wider, and mobilizable public to appeal to for support. In 1946 politicians in French West Africa organized a federation-wide political association, the African Democratic Rally (RDA). The RDA and its members in the French National Assembly aligned themselves with the French Communist Party, the only effective opposition to the governments of the Fourth Republic. The result, during 1948–50, was the virtual suppression of the RDA in Africa by the colonial administrations.

In British West Africa the tensions were greatest in the Gold Coast. In 1947 the established politicians brought in Kwame Nkrumah, who had studied in the United States and Britain and had been active in the Pan-African movement, to organize a nationalist party with mass support. In 1948 European trading houses were boycotted, and some rioting took place in the larger towns. An official inquiry concluded that the underlying problem was political frustration and that African participation in government should be increased until the colony became self-governing. In 1951, therefore, a new constitution was introduced in which the legislative council gave way to an assembly dominated by African elected members, to which African ministers were responsible for the conduct of much government business. By this time Nkrumah had organized his own mass political party, able to win any general election, and during the following years he negotiated with the British a series of concessions that resulted in 1957 in the Gold Coast becoming the independent state of Ghana.

Once the British had accepted the principle of cooperating with nationalist politicians, their other western African colonies began to follow the example set by the Gold Coast. But Nkrumah had been greatly aided by the high price for cocoa in the 1950s (which meant that by 1960 Ghana's trade was worth $630 million a year and that government revenue, at more than $280 million, was broadly adequate to give the people what they wanted in the way of modernizing programs) and by the comparatively high level and generally wide spread of education in a sizable yet compact territory that was without too serious ethnic divisions. The other colonies were not so well placed.

The small size of The Gambia was the principal factor contributing to the delay of its independence until 1965. Sierra Leone was a densely populated country that was appreciably poorer than Ghana (its GNP per capita, at about $70, being approximately one-third of Ghana's) and in which there was a wide disparity in levels of education and wealth between the Creoles—the descendants of liberated slaves who lived in and around Freetown—and the rest of the people. When independence was achieved in 1961, these deeply rooted problems had been papered over rather than solved.

Nigeria presented the greatest challenge to British and African policymakers alike. In the south two nationalist parties emerged, the Action Group (AG), supported primarily by the Yoruba of the west, and the National Convention of Nigerian Citizens (NCNC), whose prime support came from the Igbo of the east. These parties expected the whole country quickly to follow the Ghanaian pattern of constitutional change. But any elective central assembly was bound to be dominated by the north, which had some 57 percent of the population and whose economic and social development had lagged far behind. The north's political leaders—most of whom were conservative Muslim aristocrats closely allied with the British through indirect rule—were not at all eager to see their traditional paramountcy invaded by aggressive and better-educated leaders from the south.

The first political expedient was to convert Nigeria into a federation of three regions. In 1957 this allowed the east and the west to achieve internal self-government without waiting for the north, but it left open the questions of how politics were to be conducted at the centre and how Nigerian independence was to be secured. At this juncture it occurred to the northern leaders that by allying themselves to one of the southern parties they might maintain their local monopoly of power and gain prestige in the country as a whole by asking for its independence. The problem of central politics was thus resolved when the northern leaders entered a coalition federal government with the NCNC, and in 1960 Nigeria became independent.

Meanwhile, in French West Africa the RDA, led by Félix Houphouët-Boigny, broke with the Communist Party. The votes of a small bloc of African deputies in the French National Assembly were of considerable value to the shifting coalitions of non-Communist parties that made up the unstable French governments of the 1950s, and the RDA began to seek to influence these governments to allow greater freedom to the colonies.

By 1956 Houphouët-Boigny's policy had secured a widening of the colonial franchises and the beginnings of a system by which each colony was on the way to becoming a separate unit in which African ministers would be responsible for some of the conduct of government. The implications of this approach, however, did not meet with the approval of some other African leaders, most notable among them Léopold Sédar Senghor in Senegal and Ahmed Sékou Touré in Guinea. Senghor had stood outside the RDA since the days of its alliance with the Communists, which he had thought could only bring disaster. Together with Sékou, who had remained within the RDA, he argued that Houphouët's policy would split up the western African federation into units that would be too small and poor to resist continued French domination.

In 1958 the French Fourth Republic collapsed and de Gaulle was returned to power. On Sept. 28, 1958, in a referendum, the colonies were offered full internal self-government as fellow members with France of a French Community that would deal with supranational affairs. All of the colonies voted for this scheme except Guinea, where Sékou Touré led the people to vote for complete independence. Senegal and the French Sudan were then emboldened in 1959 to come together in a Federation of Mali and to ask for and to receive complete independence within the community. These two territories separated in the following year, but all the others now asked for independence before negotiating conditions for association with France, and by 1960 all the former French colonies were de jure independent states.

By that time only the excessively conservative regimes of Portugal and Spain sought to maintain the colonial principle in western Africa. Encouraged and aided by independent neighbours, Guinean nationalists took up arms in 1962 and after 10 years of fighting expelled the Portuguese from three-quarters of Portuguese Guinea. In 1974 the strain of this war and of wars in Mozambique and Angola caused the Portuguese people and army to overthrow their dictatorship. Independence was quickly recognized for Guinea-Bissau in 1974 and for the Cape Verde Islands and São Tomé e Príncipe in 1975.

Spain concluded in 1968 that the best way to preserve its interests in Equatorial Africa was to grant independence to its people without preparing them for it. The result was chaos. Potential phosphate riches led Spain to hold on to the Spanish Sahara, however, until the death of Francisco Franco in 1975, and growing pressure from Morocco led to agreements by which, in the following year, despite an armed nationalist revolt sponsored by Algeria, the territory was partitioned between Morocco and Mauritania. In 1976, under Algerian sponsorship, the nationalists proclaimed the Sahrawi Arab Democratic Republic. Mauritania signed an agreement with the nationalists' armed wing, the Popular Front for the Liberation of Saguia el Hamra and Rio de Oro (Polisario) in 1979 and renounced all claims to its sector, but Morocco refused to yield its sector and engaged in an armed struggle with the Polisario over the territory.   (J.D.F.)

WESTERN AFRICA SINCE INDEPENDENCE

Western Africa's political history since independence has been dominated by two factors. First, the hopes raised by political independence in many countries were not realized. National leaders clung to personal power and frustrated expectations of political evolution along democratic lines, with corruption, self-seeking, and a loss of political direction as a consequence. Dissatisfaction was commonly focused on the military, which in most states was the only institutionalized authority apart from the government. Since the 1960s western Africa has been characterized by a pattern of military coups. In some states successive coups have taken place as one military faction replaced another; in others, the army has intervened as periodically as restored civilian regimes have failed.

Second, the relative economic position of western Africa has seriously declined since independence. Government mismanagement has played a part, but significant underlying factors have played a larger role. At independence few states had the economic resources to satisfy popular

AG and NCNC in Nigeria

Margin notes (right column):
Intimations of imperial decline

Regional economic decline

expectation. Internationally approved, ambitious public- and private-sector industrial modernization programs were often ill-judged and harmful to the agricultural sector. A declining capacity to feed themselves led in many states to costly import substitution. At the same time, export crops were dependent on declining world market prices, and the price of imported oil rose spectacularly in the 1970s. Many states experienced chronic balance-of-trade deficits and incurred crippling international debts. In the 1970s and '80s drought and famine exacerbated the situation. A deepening indebtedness and difficult and prolonged nego- tiations with lending and rescheduling agencies such as the International Monetary Fund (IMF) and the World Bank resulted and continued into the 21st century.

Francophone countries. In Senegal, Léopold Senghor, with strong French support, maintained power until his resignation in 1980 by balancing conflicting factions and promising controlled political liberalization. His nomi- nated successor, Abdou Diouf, continued these general policies together with the link to France. In the 1980s Senegal experienced budget deficits and agreed to a pro- gram of fiscal restraint with the IMF and the World Bank, which was continued by Abdoulaye Wade when he became president in 2000.

Côte d'Ivoire was ruled after independence by the strong- ly pro-French Félix Houphouët-Boigny, who died during his seventh term in office in December 1993. A period of sustained economic growth, marked by significant foreign investment, ended in the 1980s. The country was further harmed by political strife in the 1990s and civil war in the early 21st century.

In Guinea, Ahmed Sékou Touré held power from in- dependence in 1958 to his death in 1984. Initially he re- pudiated any connection with France and the Western powers. Guinea adopted a variant of international Marx- ism, experienced a number of internal political crises, and embraced economic policies that ran into trouble in the 1970s. Following Sékou Touré's death, the army seized power. President Lansana Conté survived a coup attempt in 1985 and, with a ruined economy, accepted a stringent IMF and World Bank retrenchment program. The coun- try's first multiparty elections were held in December 1993, but continuing economic hardship led to ongoing unrest within Guinea that continued into the 21st century.

In Cameroon, Ahmadou Ahidjo successfully created a unified state from French and British trusteeship territo- ries, but his government became increasingly authoritari- an. In 1979 there was a regional uprising, an attempted coup, and an upsurge of covert opposition from Anglo- phone elements. In 1982 Ahidjo resigned the presidency in favour of the prime minister, Paul Biya, who ruled into the 21st century. In 1984 another coup attempt by the army was suppressed with considerable violence. Biya's reasser- tion of presidential authority thereafter was greatly assist- ed by access to oil revenues. Cameroon has experienced significant if sometimes fragile economic growth and has good economic prospects.

Chad became independent in 1960. In 1975 the historic division between the Muslim north and non-Muslim south had erupted in violence. Prolonged warfare followed, in which France and Libya intervened. Chad remains a po- litically unstable country with major economic problems, although the development of oil reserves that began in 2000 hold economic promise. In Mali, Modibo Keita was oust- ed by the army in 1968. The successor regime was over- thrown in 1991. A new constitution in 1992 established a secular, multiparty state. The 1980s, '90s, and 2000s have been dominated by chronic deficits in foreign trade and an economic crisis that was deepened by severe droughts.

In Niger, Hamani Diori was removed in 1974 owing to the economic hardships that followed severe drought. His successor, Seyni Kountché, used uranium revenues to con- solidate his rule, but by the time Kountché died in 1987, the uranium boom had ended. Subsequent leaders inherit- ed an economy distressed by debt and political strife. Niger entered the 21st century struggling to maintain peace and improve its dismal economic situation.

Upper Volta experienced a series of coups as successive civilian and military regimes unsuccessfully grappled with a disabled economy. In 1983 Captain Thomas Sankara as- sumed power. He changed the name of the country to Burkina Faso in 1984. Sankara was a charismatic figure who undertook socialist agricultural initiatives. These foundered, but Sankara refused to approach the IMF. In 1987 he was assassinated and replaced by Captain Blaise Compaoré, who ruled into the 21st century. State capital- ism replaced Sankara's socialism, and overtures were made to the IMF in an attempt to solve the chronic trade deficit.

Dahomey, which changed its name to Benin in 1975, suf- fered five military coups until, in 1972, Major Mathieu Kérékou seized power. Kérékou's Marxist sympathies aroused widespread apathy and disillusionment. In the 1980s socialism was cautiously abandoned, and Benin was opened to foreign investment. In 1984 public-sector cuts were instituted under IMF oversight, but retrenchment alienated Benin's large educated elite and those with so- cialist leanings. Despite much progress having been made since the late 1980s, Benin's economy was still under- developed at the beginning of the 21st century.

In Mauritania, the government of Moktar Ould Daddah was unable to cope with drought, poverty, and military confrontation with Algerian-supported Polisario Front na- tionalist guerrillas in Western Sahara (formerly Spanish Sa- hara). In 1978 it was replaced by the military, which concluded peace with the Polisario Front but became em- broiled in hostilities with Morocco. In 1984 Colonel Maaouya Ould Sidi Ahmed Taya replaced Colonel Mo- hamed Khouna Ould Haidalla in a bloodless coup and re- stored diplomatic relations with Morocco. Throughout the 1980s the government was plagued by internal ethnic con- flicts between black Africans and Muslims of Arab extrac- tion. Taya was ousted in a coup in 2005.

In Togo, the army intervened twice in the 1960s, and since 1967 the country has been ruled by General Gnass- ingbé Eyadéma. Togo benefited from phosphate revenues until this boom collapsed in the mid-1970s. From 1979 Togo periodically resorted to the IMF for help with eco- nomic stabilization and debt rescheduling. General Eyadé- ma ruled until his unexpected death in 2005 and was succeeded by his son, Faure Eyadéma.

Anglophone countries. Nigeria, among the former British colonies, is the demographic giant of western Africa. It has a wealth of resources, but its federal structure has been threatened by regional and ethnic rivalries. In 1964 political arrangements broke down under these strains, and in 1966 the army intervened in an attempt to create a unitary government. Regional rivalries deepened, and in 1967 Igbo officers from eastern Nigeria declared a secessionist republic of Biafra. After three years of warfare the federal government of General Yakubu Gowon liqui- dated Biafran independence. Gowon tried to prevent fu- ture secession by enlarging the number of regional states to 12 (increased to 19 in 1976), but his government lost sup- port because of its perceived reluctance to surrender power. Gowon was toppled in 1975 by a coup led by Brigadier Murtala Ramat Mohammed, who was himself assassinated in 1976. The army continued in power under General Olusegun Obasanjo, who instituted measures to restore Nigeria to civilian rule. In 1979 multiparty elec- tions led to the formation of the Second Republic under President Alhaji Shehu Shagari, who in mid-1983 won a second term. By then, however, the revenues generated by Nigeria's oil boom in the 1970s were drying up. There was a widespread belief that Nigeria's oil wealth had been cor- ruptly squandered, and at the end of 1983 the Second Re- public was replaced by a military regime under Major General Mohammed Buhari. In 1985 Buhari was himself replaced in a military coup by General Ibrahim Babangi- da, who promised to return Nigeria to civilian rule by 1992. Babangida failed to do this and resigned in August 1993. An interim government was installed, but the first elections for civilian rule were annulled. General Sani Abacha seized power in 1993 and ruled until his death in 1998; civilian rule was restored the next year and contin- ued into the 21st century.

In 1957 Ghana achieved independence under the charis- matic leadership of Kwame Nkrumah. His prominence in the international arena was offset by corruption and an in-

Socialism in Burkina Faso and Benin

creasingly autocratic political machine. In 1966 Nkrumah was overthrown by the army. In 1969, under military tutelage, the Second Republic was instituted under Kofi Busia. The successive regimes of Generals Ignatius Kutu Acheampong and Frederick W.K. Akuffo failed to resolve Ghana's deepening economic crisis. The military reluctantly promised a return to civilian rule in 1979. In June of that year, however, a group of junior officers under Flight Lieutenant Jerry Rawlings carried out a coup, purged senior figures in the army, and held elections. But the Third Republic, headed by Hilla Limann, proved incapable of reversing economic catastrophe, and in 1981 Rawlings led another coup. In the 1980s and '90s the government headed by Rawlings pursued broadly socialist programs of democratization. At the same time it tackled Ghana's long-term economic decline and concluded a wide-ranging structural adjustment program with the IMF and the World Bank. The Fourth Republic was inaugurated in 1993, and Rawlings continued to rule until he stepped down in 2000; John A. Kufuor was elected to succeed him.

In Sierra Leone there were military coups in 1967 and 1968, and then the army installed Siaka Stevens at the head of a civilian government. In 1985 Stevens was succeeded by General Joseph Saidu Momoh. Momoh's regime was marked by economic difficulties. Relations with the IMF fluctuated, chiefly because IMF-recommended austerity measures produced widespread unrest. Momoh was overthrown in 1992, and the civil war that began a year earlier continued until 2002.

Gambia achieved independence in 1965. The country later formed the confederation of Senegambia with Senegal in 1982, but the confederation disbanded in 1989. The Gambian government faced serious economic problems in the 1980s and instituted a series of austerity measures. A coup in 1994 led to a period of military rule, but civilian rule was restored by 1997. Gambia typically has a trade deficit and remained dependent on foreign aid in the early 21st century.

Lusophone countries. The Lusophone states of western Africa have also experienced problems. Since gaining independence in 1974, Guinea-Bissau has been plagued with economic and political strife, which was exacerbated by a brief civil war in the late 1990s. The country remained heavily dependent on foreign aid in the early 21st century.

After gaining independence in 1975, Cape Verde remained politically stable and became a multiparty democracy in 1992. Although the government has since made strides in reaching economic goals, poverty and high rates of unemployment continued to plague the country into the early 21st century.

Liberia. Liberia, the only western African state not formally colonized by a European power, has also been beset by political and economic problems. During President William V.S. Tubman's long tenure in office (1944–71), the ruling Afro-American True Whig Party concluded that its maintenance of power depended on an economic and political partnership with the indigenous African Liberians. Tubman's successor, President William R. Tolbert (1971–80), sought ways to implement this policy. In 1979, however, long-term inequalities, rural poverty, and economic mismanagement produced serious food riots. In 1980 government repression precipitated a military coup led by Master Sergeant (later Commander in Chief) Samuel K. Doe. Doe was unable to resolve the country's economic problems, and in 1986 the IMF and World Bank withdrew from Liberia. Civil war led to Doe's downfall and murder in 1990 and to the subsequent and highly criticized rule of Charles Taylor. The war ended in 2003, and Liberia began the arduous task of rebuilding the country. Presidential elections were held in late 2005. Ellen Johnson-Sirleaf was declared the winner; she became the first woman to be elected head of state in Africa.

COUNTRIES OF THE WESTERN SUDAN

Burkina Faso

Burkina Faso is a landlocked state in western Africa with an area of 103,456 square miles (267,950 square kilometres). A former French colony, it gained independence as Upper Volta (République de Haute-Volta) in 1960; the name Burkina Faso was adopted in 1984. The country is bounded to the north and west by Mali, to the south by Côte d'Ivoire, Ghana, and Togo, and to the east by Benin and Niger. The capital, Ouagadougou, is about 500 miles (800 kilometres) by road from the sea.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Burkina Faso consists of an extensive plateau, which is slightly inclined toward the south. The lateritic (red, leached, iron-bearing) layer of rock that covers the underlying crystalline rocks is deeply incised by the country's three principal rivers—the Black Volta, Red Volta, and White Volta—all of which converge in Ghana to the south to form the Volta River. The Oti, another tributary of the Volta, rises in southeastern Burkina Faso. In the southwest there are sandstone plateaus bordered by the Banfora Escarpment, which is about 500 feet (150 metres) high and faces southeast. The country is generally dry and the soil infertile. Great seasonal variation occurs in the flow of the rivers, and some become dry beds in the dry season.

Climate. The climate is generally sunny, hot, and dry. In the north the climate is semiarid steppe, known locally as the Sahelian type and characterized by three to five months of rainfall, which is often erratic. To the south it becomes increasingly of the tropical wet-dry type sometimes called Sudanic, characterized by greater variability of temperature and rainfall and greater total rainfall.

Four seasons may be distinguished in Burkina Faso: a dry and cool season from mid-November to mid-February,

with temperatures dropping to about 60° F (16° C) at night; a hot season from mid-February to June, when maximum temperatures rise to about 104° F (40° C) in the shade and the harmattan—a hot, dry, dust-laden wind blowing off the Sahara—is prevalent; a rainy season, which lasts from June to September; and an intermediate season, which lasts from September until mid-November. Annual rainfall varies from about 40 inches (1,000 millimetres) in the south to less than 10 inches in the north.

Plant and animal life. The northern part of the country consists of savanna, with prickly shrubs and stunted trees that come to life during the rainy season. In the south the prickly shrubs give way to scattered forests, which become more dense along the banks of the perennial rivers. While tree growth in the north is discouraged by the climate, farmers in the south often permit only useful trees, such as the karite (shea tree) or the baobab, to survive.

Animal life in the eastern region includes buffalo, antelope, lions, hippopotamuses, elephants, and crocodiles. Elephants, buffalo, and antelope are also found in the southeast and on the banks of the Black Volta, while herds of hippopotamuses are to be seen some 40 miles from the city of Bobo Dioulasso. Animal life also includes monkeys. Bird and insect life is rich and varied, and there are many fish in the rivers.

Settlement patterns. The population as a whole is unevenly distributed among the different regions. The Mossi country is densely settled. Situated in the eastern and central regions, it contains about two-thirds of the total population. In the remaining regions the population is scattered.

About four-fifths of the population is rural—the highest proportion in western Africa—and lives in some 7,700 villages. Villages tend to be grouped toward the centre of the country at higher elevations away from the Volta valleys. For several miles on either side of the Volta rivers, the land is mostly uninhabited because of the prevalence of

the deadly tsetse fly, which carries sleeping sickness, and the simulium fly, which carries onchocerciasis, or river blindness.

Ouagadougou, the administrative capital and the seat of government, is a modern town in which several commercial companies have their headquarters. It is also the residence of the *morho naba*, emperor of the Mossi, and an important regional centre for international aid programs.

The principal towns

Apart from Ouagadougou, the principal towns are Bobo Dioulasso, Koudougou, Ouahigouya, Kaya, Fada Ngourma, and Banfora. Bobo Dioulasso, in the west, was the economic and business capital of the country when it formed the terminus of the railroad running to Abidjan, Côte d'Ivoire, on the coast; since 1955, however, when the railroad was extended to Ouagadougou, it has lost some of its former importance, although it remains a commercial centre.

The people. Two principal ethnic groups live in Burkina Faso. The first of these is the Voltaic (Gur) group, which may be further divided into five subgroups—the Mossi, which include the Gurma and the Yarse, the Gurunsi, the Senufo, the Bobo, and the Lobi. The second group is the Mande family, which is divided into four subgroups: the Samo, the Marka, the Busansi, and the Dyula. In addition, there are Hausa traders, Fulani herders, and the Tuareg, or rather their settled servants, the Bella.

Each of the ethnic groups found in Burkina Faso has its own language, although Moré, the language of the Mossi, is spoken by a great majority of the population and Dyula and Hausa are widely used in commerce. French, the official language, is used for all communication with other countries. About one-third of the population are animists, attaching great importance to ancestor worship. Islām exerts an increasing influence upon customs, and Muslims account for about one-half of the population. The seat of the Roman Catholic archbishopric is Ouagadougou, and there are eight bishoprics. There are few Protestants in the country.

In the early 21st century, yearly population growth averaged more than 2 percent; nearly one-half of the population is below the age of 15. Average life expectancy is slightly below the average for western Africa.

The economy. Most of the population is engaged in subsistence agriculture or stock raising. Difficult economic conditions, made worse by severe intermittent droughts, have provoked considerable migration from rural to urban areas within Burkina Faso and to neighbouring countries such as Côte d'Ivoire and Ghana. More than one-third of the country's labour force may be abroad at any given time.

The development of industry in Burkina Faso is hampered by the small size of the market economy and by the absence of a direct outlet to the sea.

Resources. Minerals, especially manganese and gold, represent potential wealth for this otherwise poorly endowed country. Gold mines at Poura, southwest of Koudougou, have been developed and intermittently operated, and smaller gold deposits are known to exist in other parts of the country. Reserves of nickel, bauxite, lead, phosphates, titanium, vanadium, zinc, and limestone are being studied, with some development occurring with the last two. Substantial manganese deposits at Tambao in the northeast were developed in the 1990s, but limited output and transportation complications hindered the economic viability of the project.

Agriculture. Agricultural production consists of subsistence foodstuffs, with the surplus being sold as cash crops. Surplus cotton is an important export in Burkina Faso, and surplus shea nuts are also exported. Sorghum, millet, corn (maize), peanuts (groundnuts), rice, sesame, and sugarcane are grown for local consumption. Stock raising, a principal source of revenue, includes cattle, sheep, goats, pigs, donkeys, horses, and camels. Chickens, ducks, and guinea fowl are also raised.

Industry. Industry is limited to a number of plants, mainly in the cities and larger towns, that produce processed sugar, beer, soft drinks, edible oils, soap, and flour, and that assemble bicycles.

Finance. Burkina Faso, along with other French-speaking states in western Africa, is a member of the West African Economic and Monetary Union. These states share a common central bank, with headquarters in Dakar, Senegal, and a common currency, the CFA (Communauté Financière Africaine) franc. Branches of the central bank in Burkina Faso are located in Ouagadougou and Bobo Dioulasso. Among the partially or wholly state-owned commercial banks, the most important is the Banque Internationale du Burkina in Ouagadougou. Burkina Faso is also a member of the Economic Community of West African States (ECOWAS), a body encompassing most states in western Africa, which attempts to integrate and harmonize the economic interests of the region. One of the poorest countries in the world, Burkina Faso relies heavily on international aid and on remittances from migrants to help offset its current account deficit.

Trade. External commerce, both in imports and in exports, is primarily with France, Côte d'Ivoire, Japan, and neighbouring countries. Many cattle are exported to Côte d'Ivoire and to Ghana. There is a deficit in the balance of payments, largely due to the relatively small amounts of exports, which are not of sufficient value to equal the value of imported materials required for promoting further development.

Transportation. In addition to the rail line that links Ouagadougou to the port of Abidjan in Côte d'Ivoire, the capital is also linked by road to the principal administrative centres in the country and to the capitals of neighbouring countries. The railroad to Abidjan is 712 miles long, of which 321 miles run through Burkina Faso. Running from east to west before crossing the border, the line serves the towns of Koudougou, Bobo Dioulasso, and Banfora.

Burkina Faso has one of the most poorly developed road networks in proportion to its size among the western African states. Only about a quarter of the network is usable year-round. The remainder consists mostly of unpaved rural roads. Three important road-building projects completed in the late 1960s and early 1970s were financed by the European Development Fund. The first of these roads runs from Bobo Dioulasso to Faramana to the Mali frontier, the second from Ouagadougou to Pô to the Ghanaian frontier, and the third from Ouagadougou to Koupéla. Additional internationally aided road maintenance and improvement programs, particularly in the country's northeast, were carried out in the 1980s and '90s.

International airports are located at Ouagadougou and Bobo Dioulasso. Internal air service, linking about 50 smaller airstrips, is supplied by the national airline.

Administration and social conditions. *Government.* A constitution, adopted by referendum in 1991, allowed for multiparty elections and a parliamentary republic with a president as chief of state and a prime minister as the head of the government. The president is elected by universal suffrage to a five-year term. The legislative branch of the government is represented by the National Assembly, whose members are elected to a five-year term by universal suffrage. The constitution provides for an independent judiciary.

Local government

Burkina Faso is divided into 45 provinces, which, in turn, are divided into 382 *départements*. Each province is administered by a high commissioner.

Education. Although primary education is free and compulsory for six years, school enrollment figures in Burkina Faso are among the lowest in western Africa. French is the language of instruction in primary and secondary schools. Higher education is sought at Ouagadougou University (established 1974). Other institutes in Ouagadougou sponsored by neighbouring francophone states offer degrees in rural engineering and hydrology. Some students seek higher education in France; in Dakar, Senegal; or in Abidjan, Côte d'Ivoire.

Health and welfare. The state of health of the Burkinabé is very poor. Periodic droughts have contributed to malnutrition and related diseases, especially among young children and pregnant women. Only about one-third of the people have access to safe drinking water.

Gastrointestinal diseases and malaria are the main causes of death. Onchocerciasis, sleeping sickness, leprosy, yellow fever, and bilharzia are also endemic. The government carried out a successful child-immunization program in 1985, as a result of which infant and child mortality have decreased, though adult mortality has not. Hospitals exist only in the leading towns, but the government improved primary health care by raising the number of village clinics to 7,000.

Cultural life. Folklore is rich, reflecting the country's ethnic diversity. On national occasions each region is represented in the capital by its own folkloric group.

Ouagadougou draws large numbers of visitors to the biennial Pan-African Film Festival (FESPACO). The International Crafts Fair, which is held in alternate years, celebrates the rich and diverse craft production of the nation's artisans. Several daily newspapers are published, including the government-sponsored *Sidwaya*, as well as a number of weeklies. There are three national parks—those of Po, Arly, and in the east, straddling the border with Benin and Niger, the great "W" National Park.

For statistical data on the land and people of Burkina Faso, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.   (P.H.Gu./M.Ec.)

HISTORY

Early history. Axes belonging to a Neolithic culture have been found in the north of Burkina Faso. The Bobo, Lobi, and Gurunsi are the earliest known inhabitants of the country. In about the 15th century AD conquering horsemen invaded the region from the south to found the Gurma and the Mossi kingdoms, in the eastern and central areas, respectively. Several Mossi kingdoms developed, the most powerful of which was that of Ouagadougou, in the centre of the country. Headed by an emperor titled the *morho naba* ("great lord"), the Ouagadougou Mossi state defeated attempted invasions by Muslim Songhai and Fulani neighbours yet maintained valuable commercial links with major western African trading powers such as the Dyula, the Hausa, and the Asante (Ashanti).

European exploration and colonization. The German explorer Gottlob Adolf Krause traversed the Mossi country in 1886; and the French army officer Louis-Gustave Binger visited the *morho naba* in 1888. France obtained a protectorate over Yatenga in 1895; and Paul Voulet and Charles-Paul-Louis Chanoine defeated the *morho naba* Boukari-Koutou (Wobogo) in 1896 and then proceeded to overrun the Gurunsi lands. The Gurma accepted a French protectorate in 1897; and in 1897 likewise the lands of the Bobo and of the Lobi were annexed by the French (though the Lobi, armed with poisoned arrows, were not effectively subdued until 1903). An Anglo-French convention of 1898 fixed the frontier between France's new acquisitions and the northern territories of the Gold Coast.

The French divided the country into administrative *cercles* ("circles") but maintained the chiefs, including the *morho naba*, in their traditional seats. At first attached to French Sudan (or Upper Senegal-Niger, as that colony was called from 1904 to 1920), the country was organized as a separate colony, Upper Volta (Haute-Volta), in 1919. In 1932 it was partitioned between Côte d'Ivoire, Niger, and French Sudan. In 1947, however, Upper Volta was reestablished to become an overseas territory of the French Union, with a territorial assembly of its own. The assembly in 1957 received the right to elect an executive council of government for the territory, which at the end of 1958 was transformed into an autonomous republic within the French Community. When independence was proclaimed on Aug. 5, 1960, the new constitution provided for an executive president elected by universal adult suffrage for a five-year term and an elected Legislative Assembly.

(H.J.D./Je.D./M.Ec.)

Independence. Since Burkina Faso became an independent nation, the military has on several occasions intervened during times of crisis. In 1966 the military, led by Lieutenant-Colonel (later General) Sangoulé Lamizana, ousted the elected government of Maurice Yaméogo. General Lamizana dominated the nation's politics until November 1980, when a series of strikes launched by

workers, teachers, and civil servants led to another coup, this time headed by Colonel Saye Zerbo.

Colonel Zerbo's short-lived rule ended in November 1982, when noncommissioned army officers rebelled and installed Major Jean-Baptiste Ouedraogo as president. The Ouedraogo government soon split into conservative and radical factions, with the radicals seizing power on Aug. 4, 1983. They set up a National Revolutionary Council (CNR) with Captain Thomas Sankara as head of state.

A year after taking power, Sankara renamed the country Burkina Faso, meaning "Land of Incorruptible People," and ordered all officials, including himself, to open their bank accounts to public scrutiny. His government was successful at promoting vaccination and housing projects, tree planting to hold back the Sahel, women's rights, and curbing government waste.

Initially a coalition of radical groups that included army officers, trade unionists, and members of small opposition groups, the Sankara regime gradually lost most of its popular support as power became concentrated in the hands of a few military officers—the most important of which were Sankara, Captain Blaise Compaoré, Major Jean-Baptiste Boukari Lingani, and Captain Henri Zongo. As popular support continued to decline, on Oct. 15, 1987, a military coup led by Compaoré overthrew Sankara, killing him and eight others.

Compaoré took power at the head of a triumvirate that also included Captain Zongo and Major Lingani. Calling themselves the Popular Front (FP), they promised to adhere to the original principles of the Sakara revolution. The FP stressed self-sufficiency in food and less strident relations with conservative states in the region, especially Togo and Côte d'Ivoire. Zongo and Lingani were executed in 1989 after the discovery of a coup plot was alleged. In 1996 the Popular Front became the Congress for Democracy and Progress, a party that was formed from at least 10 other parties.

Compaoré was the only presidential candidate in elections held in 1991; he won although more than 70 percent of the voters boycotted the election. Multiparty elections occurred in 1998, but Compaoré was again the winner. Compaoré attempted to appease the population by creating the "College of Elders," which consisted of prominent elders, citizens, and religious leaders, one of whose suggestions was a national day of forgiveness that first took place in March 2001. Continuing political tensions, however, including demands to investigate the deaths of several prominent persons, forced Compaoré to face difficult problems; constitutional reforms virtually ensured he could be in power for the first decade of the 21st century.

For later developments in the history of Burkina Faso, see the BRITANNICA BOOK OF THE YEAR.   (M.Ec.)

Cape Verde

Cape Verde (República de Cabo Verde) is a republic comprising a group of islands that lie 385 miles (620 kilometres) off the west coast of Africa, between 14°30′ and 17°30′ N and between 22°30′ and 25°30′ W, with a total land area of 1,557 square miles (4,033 square kilometres). Praia on São Tiago is the capital.

PHYSICAL AND HUMAN GEOGRAPHY

Cape Verde is named after the westernmost cape of Africa, which is the nearest point on the continent. The country consists of 10 islands and five islets, which are divided into the Windward (Barlavento) and Leeward (Sotavento) groups. The Windward Islands consist of Santo Antão, São Vicente, Santa Luzia, São Nicolau, Boa Vista, and Sal, together with the islets of Raso and Branco. The Leeward Islands include Maio, São Tiago (Santiago), Fogo, and Brava and the three islets called the Rombos—Grande, Luís Carneiro, and Cima.

The largest port in the islands is Porto Grande at Mindelo, on São Vicente. Its deepwater harbour accommodates sizable vessels and is used primarily as a fueling station.

The land. *Relief, drainage, and soils.* The islands are mountainous and are volcanic in origin. Only the three oldest—Boa Vista, Maio, and Sal, the so-called Rasas

("Flat") islands—have suffered enough erosion to have much level ground. Fogo (meaning "Fire") has an active volcano, Mount Cano, whose last major eruption was in 1951. Its cone rises 9,281 feet (2,829 metres) above sea level. The peak of Mount Coroa on Santo Antão is 6,493 feet. São Tiago and São Nicolau both have mountains more than 4,200 feet high. All the islands, especially the Windwards, have been eroded by sand carried by high winds, so that the outline of the landscape appears jagged.

There are few watercourses that run all year, and even these do not reach their ends during the dry season. Dry watercourses fill up for several days during the short, intense rainy season. Rains tend to occur as torrential storms, causing severe soil erosion and great damage to agriculture. Groundwater is the primary source of domestic water supply. Some groundwater sources, however, are sulfurous; others, mainly on São Vicente and Boa Vista, are slightly salty due to the low water tables.

Almost a quarter of the land area is rock of volcanic origin; basalt is a common type. More than 60 percent of the land is arid and lacking in humus and thus is suitable only for rough grazing. Sand and limestone outcrops are common in these areas. The remaining 15 percent is fertile; it contains alluvial deposits and is suitable for irrigation.

Soil erosion has been one of Cape Verde's greatest problems. It began to have a serious effect in the early 19th century, attributable to overgrazing by goats. Since independence a nationwide campaign to prevent erosion has been under way, involving planting drought-resistant varieties of acacia trees (which now cover 7.5 percent of the land surface), building small dikes, and improving farming techniques.

Climate. Moderate, stable temperatures and extreme aridity characterize the climate. February is the coolest month, with an average temperature of 71° F (22° C), and September is the warmest, having an average of 80° F (27° C). The islands are almost constantly under the influence of a dry northeast wind. Consequently there is almost no rainfall, except for a period from August through October, when an average of 1.6 inches (39 millimetres) a month is recorded. These rains can fail for years at a time.

Plant and animal life. On islands higher than 1,000 feet, which includes most of the larger islands, elevations are great enough to generate rainfall on the windward slopes. Grasses and some pine plantations are found in these relatively moist locations. The leeward slopes, however, exhibit a characteristic rain shadow effect that produces desert conditions, and the sparse shrub cover almost disappears. The shrubs remaining in these areas are mostly thorny or bitter; some are toxic. A sea mist on the higher hills permits some agriculture, and irrigated valley bottoms are densely cultivated. Salt areas on Maio and Sal have interesting xerophilous plants.

The scarcity of water limits the number of land turtles in the archipelago, but two species of sea turtles lay their eggs on the sandy shores of the uninhabited islets. There are many geckos, lizards, and several species of skinks. A species of giant skink is protected by law, but it may be extinct. There are 19 known species of butterflies, but none is endemic, and all the species are of African origin.

There are 105 known species of birds, of which only 38 breed regularly, including four species of petrels and two of shearwaters. Other bird species include the greater flamingo, the frigate bird and the buzzard (both nearly exterminated), the Egyptian vulture, the Cape Verde Islands kite, and the red-billed tropic bird. Several other birds are represented by local species, of which the kingfisher is among the most conspicuous. The only truly endemic species, however, are the cane warbler and the Raso lark, which is restricted to Raso, one of the smallest uninhabited islets. The rest of the birds are overseas migrants. Remarkably, gulls and terns do not breed on the islands.

Mammals of Cape Verde include the feral goats found on Fogo, the descendants of domestic goats that were brought to the islands. The islands' rodent population probably originated with rodents brought on early ships. The long-eared bat is the only indigenous mammal.

Settlement patterns. The majority of the population is rural, living in small villages in fertile valleys or on the coast in fishing communities. Proximity to a water supply is the determining feature in settlement location. There are three urban centres: Praia, Mindelo, and the island of Sal (centred on the international airport at Espargos). Their continuing growth and development are based on good access to transportation networks.

The people. The overwhelming majority of the islands' population is Creole (mulatto), the descendants of early contacts between Portuguese settlers and Africans brought as slaves to work on the plantations in the 16th century. Among the latter, Fulani (Fula) and Mandingo people from the region of Senegal, The Gambia, and Guinea-Bissau predominated.

Although Portuguese is the official language and is used in formal situations and for most written material, Crioulo is the mother tongue of most people. It is one of the oldest of the Portuguese creole languages. Different dialects of Crioulo exist on the different islands.

Most of the population is Roman Catholic, but a flourishing Protestant mission is based in Praia with a publishing venture in Fogo. Particularly in Sotavento, the celebration of Roman Catholic saints' days with drumming, dancing, and singing reveals the underlying African culture.

The population growth rate of more than 2 percent per year is high by world standards but is relatively low for western Africa. A steady emigration of young males seeking employment abroad and one of the lowest birth rates in sub-Saharan Africa have been responsible for dampening Cape Verde's population growth. Life expectancy, at 60 years for males and 64 years for females, is the highest in western Africa.

About half of the people live abroad as emigrant workers, often returning upon retirement. This trend began in the early 19th century with the arrival of American whaling ships that offered the opportunity for work and travel to the United States. Cape Verdeans still work on foreign merchant ships, and Boston, Mass., has a large immigrant community. During Portuguese rule, Cape Verdeans worked throughout the Portuguese empire as government officials and labourers. More recently, Portugal, The Netherlands, and France have become important destinations.

The economy. The economy is mixed, with approximately half the national production generated by state-owned concerns. Agriculture absorbs most of the labour force, although small-scale industry and services together generate a larger share of the gross national product (GNP). The mainstays of the economy are the revenue from Amílcar Cabral International Airport on Sal, foreign aid, and emigrants' remittances. These enable the balance of payments to stay generally positive despite imports far exceeding exports. As a nonaligned nation, Cape Verde receives aid from a variety of sources. There is one state bank, the Banco de Cabo Verde. The currency is the Cape Verdean escudo.

Resources. Cape Verde has few natural resources. The lack of fresh water is a problem. On São Vicente and Sal it is provided by desalination plants (which also generate electricity). Water is also obtained from springs, wells, and rainwater stored in cisterns. The country relies on imported oil for fuel. Fish are the major natural resource. Salt from Boa Vista, Maio, and Sal (meaning "Salt") was once an important export. Pozzolana, a volcanic rock that is used in making cement, is exported.

Agriculture. Bananas and coffee have been the chief agricultural exports. Crops grown for local consumption include corn (maize), sugarcane, castor beans, broad beans, potatoes, and peanuts (groundnuts). Severe and recurrent droughts affect the islands, causing unemployment and a dramatic fall in crop output. Deaths from starvation are a thing of the past, but there is a heavy reliance on imported foodstuffs. During the decade-long drought of the 1970s, 95 percent of food needs were met by imports.

Industry. Small-scale industries such as textiles and pharmaceuticals play an increasingly important role in the economy. Fish processing is becoming well established. In 1981 a cold-storage plant was opened in Mindelo, and canning facilities exist. Tuna, shark, and lobster are important exports.

Birds

Transportation. There are international air services from Sal to Lisbon, Boston, Moscow, Senegal, Guinea-Bissau, and Brazil. Within the islands, regular ferries and planes provide local service. All the islands except Brava have airports. With the exception of São Tiago the road networks are limited. There is a small national shipping line and a national airline, Transportes Aéreos de Cabo Verde (TACV). Ship repairing is carried out in Mindelo, where dry docks accommodate vessels of up to 2,800 tons deadweight.

Administration and social conditions. *Government.* After independence the African Party for the Independence of Cape Verde (PAICV) was the only legal political party. A multiparty system was introduced in 1990. A new constitution in 1992 established the president as head of state, elected by universal adult suffrage. The president, in consultation with the National Popular Assembly (also elected by universal suffrage), appoints the prime minister and the Council of Ministers. Local assemblies are headed by elected executive committees. At the middle level there are island committees, also elected by universal adult suffrage. The Supreme Tribunal of Justice, at Praia, is the highest court and oversees a network of popular tribunals at the local level.

Education. According to official policy, education is compulsory at the primary level for children aged seven to 14 years, but in the mid-1980s only two-thirds of all school-age children were enrolled in either primary or secondary schools. Secondary schooling is provided by four *liceus* and one industrial and commercial school. There are three teacher-training schools as well. The islands have no university. Only about half the adult population is literate, but the government has launched a major effort to build schools and train teachers to combat this problem.

Health and welfare. The major health problem is diarrhea in infants, caused by poor hygiene. There are isolated cases of malaria on São Tiago and leprosy on Fogo. The Ministry of Health is responsible for a network of locally run hospitals and health centres. A mother and child protection program has operated since 1977 with preventive medicine as a priority. Successful vaccination campaigns have reached 90 percent of the children. The infant mortality rate, while still high by world standards, is significantly lower than in other western African countries.

Cultural life. Portuguese customs and culture have influenced the islands, but they are blended with African traditions as well. Popular culture demonstrates the African heritage. There is a rich body of oral narratives. Popular characters in these stories are Ti Lobo and Chibinho ("Uncle Wolf and Nephew"). Improvised singing is a feature of social gatherings and festivities. The melancholic *morna,* expressing the sorrows of emigration and love, is a song form unique to Cape Verde.

Since the late 19th century, Cape Verde has produced some outstanding writers and poets. Between 1936 and 1960 the cultural magazine *Claridade* ("Clarity") was the focus for an artistic movement that marked a break with Portuguese literary traditions and established a Cape Verdean identity. Baltasar Lopes da Silva, who used the pseudonym Osvaldo Alcântara for his poetry, is a key figure from this period. Later writers have extended the movement's interest in the Creole culture to use Crioulo as well as Portuguese. Corsino Fortes is the best-known poet of this later generation.

One television channel and two government radio stations broadcast in Portuguese and Crioulo. A weekly government newspaper, *Voz di Povo* ("Voice of the People"), is published in Praia. Foreign publications circulate freely, as do local magazines. There is a publishing house, the Cape Verdean Institute of Books, which specializes in works on Cape Verdean history and culture.

For statistical data on the land and people of Cape Verde, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

There is no evidence of the islands having been inhabited prior to the arrival of the Portuguese, but it is thought that the Moors had visited Sal to collect salt supplies in pre-

(margin: Cape Verdean literature)

vious centuries. In 1460 the Portuguese navigators Diogo Gomes and António de Noli sighted Maio and São Tiago. In 1462 the first settlers from Portugal landed on São Tiago, subsequently founding there the oldest European city in the tropics—Ribeira Grande (now Cidade Velha). Sugar was planted in an attempt to emulate the success of the earlier settlement of Madeira. Cape Verde's dry climate was less favourable, but, with the development of transatlantic slave trade, the importance and the wealth of the islands increased. In 1532 the first bishop was consecrated. The prosperity of Ribeira Grande, however, attracted pirates, who attacked the city in 1541. The English later attacked it twice—in 1585 and 1592—the first time under the command of Sir Francis Drake. After a French attack in 1712, the city was abandoned. Portugal attempted to administer its possessions and commerce on the African coast through the islands. Until the 19th century, trade was controlled through the crown-issued monopoly contracts. English, French, and Dutch activity in the area meant, however, that the crown was never really able to enforce its edicts. Smuggling was rife.

(margin: The founding of Ribeira Grande)

From the 17th to the 19th century Cape Verde was famous for its woven cotton cloth (*panos*). Cotton grew easily, and indigo produced a rich blue dye. The skill of narrow-loom weaving had come with the slaves from the western African coast. The cloths were a valuable form of currency for the slave trade on the mainland.

With the decline of the slave trade (which was finally abolished in 1876) and with increasing drought, the prosperity of the islands slowly vanished. In the early 1800s, they experienced recurrent drought and famine as well as government corruption and maladministration. Conditions improved toward the end of the 1800s, with the establishment at Mindelo of a coaling station and a submarine cable station. After World War I, prosperity again declined as fewer ships visited Mindelo. The colonial administration encouraged emigration to the cocoa plantations of São Tomé and Príncipe.

The Portuguese administration of Cape Verde was unified under a governor in 1587. The status of the islands was changed in 1951 from that of a colony to an overseas province. In 1961 all of the citizens were given full Portuguese citizenship.

(margin: Portuguese administration)

During the war for independence from Portugal (1961–75) fought by its colonies in Africa, Cape Verde was used as a garrison by the Portuguese army. Some Cape Verdeans fled to Guinea-Bissau to join the African Party for the Independence of Guinea-Bissau and Cape Verde (PAIGC), under the leadership of Amílcar Cabral.

On July 5, 1975, Cape Verde became an independent republic. The first president, Aristides Pereira, had been secretary general of the PAIGC since 1973. The island republic is a member of the Organization of African Unity and of the United Nations.

Disapproval of the coup in Guinea-Bissau in 1980 prompted the dissolution of the Cape Verde branch of PAIGC and resulted in the formation in 1981 of the PAICV. President Pereira was reelected in February of the same year. In 1990 a multiparty system was established, and Antonio Mascarenhas Monteiro of the Movement for Democracy (MPD) became president in 1991 elections. Cape Verde affirmed its nonaligned status and sought foreign aid to salvage its economy and to fund development. Cape Verde plays an active diplomatic role in its relationship with the other former Portuguese colonies in Africa.

(W.M.B./C.S.Sh./Ed.)

For later developments in the history of Cape Verde, see the BRITANNICA BOOK OF THE YEAR.

Chad

The Republic of Chad (République du Tchad) is an independent landlocked state in north central Africa. It has an area of 495,755 square miles (1,284,000 square kilometres). It is bounded on the north by Libya, on the east by The Sudan, on the south by the Central African Republic, and on the west by Cameroon, Nigeria, and Niger. Chad obtained independence from France on Aug. 11, 1960. The capital, N'Djamena (formerly Fort-Lamy), is almost

1,000 miles (1,600 kilometres) by road from the western African coastal ports.

PHYSICAL AND HUMAN GEOGRAPHY

Although it is the fifth largest country on the continent, Chad—much of the northern part of which lies in the Sahara—has a population density of only about 10 persons per square mile (four persons per square kilometre). Most of the population lives by agriculture; cotton is grown in the south, and cattle are raised in the central region. Chad is one of the world's poorest countries.

The land. The frontiers of Chad, which constitute a heritage from the colonial era, do not coincide with either natural or ethnic boundaries.

Relief and drainage. In its physical structure Chad consists of a large basin bounded on the north, east, and south by mountains. Lake Chad, which represents all that remains of a much larger lake that covered much of the region in earlier geologic periods, is situated in the centre of the western frontier; it is 922 feet (281 metres) above sea level. The lowest altitude of the basin is the Djourab Depression, which is 573 feet above sea level.

In the early Holocene, possibly until as recently as 7,000 years ago, the lake stood at a level of about 1,100 feet above sea level, or some 180 feet higher than today, and was as much as 550 feet deep. At that stage Mega-Chad, as it has been called, occupied an area of some 130,000 square miles and overflowed southward via the present-day Kébi River and then over the Gauthiot Falls westward to the Benue River and the Atlantic Ocean. Older dune systems, flooded by Mega-Chad, form linear islands in the present lake and extend hundreds of miles to the east, the interdunal hollows being occupied by diatomites and other lake sediments.

The mountains   The mountains that rim the basin include the volcanic Tibesti Massif to the north (of which the highest point is Mount Koussi, with an altitude of 11,204 feet [3,415 metres]), the sandstone peaks of the Ennedi Plateau to the northeast, the crystalline rock mountains of the Ouaddaï (Wadai) region to the east, and the Oubangui Plateau to the south. The semicircle is completed to the southwest by the mountains of Adamawa and Mandara, which lie mostly beyond the frontier in Cameroon and Nigeria.

Chad's river network is virtually limited to the Chari and Logone rivers and their tributaries, which flow from the southeast to feed Lake Chad. The remaining Chad waterways are either seasonal or are of insignificant size. The Chari, which arises from headstreams in the Central African Republic to the south, is later joined from the east by the Salamat Wadi and from the west by the Ouham River, its largest tributary. After entering an ill-defined area of swampland between Niellim and Dourbali, it flows through a large delta into Lake Chad. The Chari is about 750 miles in length and has a flow that normally varies between 600 and 12,000 cubic feet (17,000 to 340,000 litres) per second, according to the season. The Logone, which for some of its course runs along the Cameroon frontier, is formed by the junction of the Pendé and Mbéré rivers; its flow varies between 170 and 3,000 cubic feet per second, and its course is more than 600 miles long before it joins the Chari at N'Djamena. The level of Lake Chad fluctuates according to the flow of these rivers, as well as according to the degree of precipitation, evaporation, and seepage. The droughts of the 1970s and early '80s in the Sahel region of western Africa reduced the lake to record low levels. By 1985 it had been reduced to a pool, immediately to the north of the Chari–Logone mouth, occupying about 1,000 square miles.

Soils. Several types of soil formation occur in Chad, apart from the sand of the desert zone and the sheer rock of the mountainous areas. On the south side of Lake Chad the soils are derived from clayey deposits that accumulated on the floor of Mega-Chad. Along the seasonally flooded banks of the Chari and Logone rivers and the Salamat Wadi, hydromorphic (waterlogged) soils occur. Tropical iron-bearing soils, red in colour, are found on the exposed folds and mounds of the Ouaddaï region's upland slopes. In the Kanem region (area north of Lake Chad) subarid soils are characteristic, except in the depressions that oc-

cur between the dunes on the shores of Lake Chad, where hydromorphic soils liable to salinization are found.

Climate. Chad's wide range in latitudes (that extend southward from the tropic of Cancer for more than 15°) is matched by a climatic range that varies from wet and dry tropical to hot arid. At the towns of Moundou and Sarh, in the wet and dry tropical zone, between 32 and 48 inches (800 and 1,200 millimetres) of rain falls annually between May and October. In the central semiarid tropical (Sahel) zone, where N'Djamena is situated, between 12 and 32 inches of rain falls between June and September. In the north rains are infrequent, with an annual average of less than one inch being recorded at Largeau.

Chad thus has one relatively short rainy season. The dry season, which lasts from December to February everywhere in the country, is relatively cool, with daytime temperatures of about 85° to 95° F (29° to 35° C) and nighttime temperatures that drop to about 55° F (13° C). From March onward it becomes very hot until the first heavy rains fall. At N'Djamena, for example, daytime temperatures average more than 100° F (38° C) between March and June. Heavy rains begin at N'Djamena in July, and average daytime temperatures drop to the low 90s F (mid-30s C), but nighttime temperatures remain in the 70s F (20s C) until the onset of N'Djamena's dry, cool season in November.

Plant and animal life. Three vegetation zones, corre-   Three lated with the rainfall, may be distinguished. These are a   vegetation wet and dry tropical zone in the south, characterized by   zones shrubs, tall grasses, and scattered broad-leaved deciduous trees; a semiarid tropical (Sahel) zone, in which savanna vegetation gradually merges into a region of thorn bushes and open steppe country; and a hot arid zone, composed of dunes and plateaus in which vegetation is scarce and occasional palm oases are to be found.

The tall grasses and the extensive marshes of the savanna zone have an abundant wildlife. There large mammals—such as the elephant, hippopotamus, rhinoceros, warthog, giraffe, antelope, lion, leopard, and cheetah—coexist with a wide assortment of birds and reptiles. The rivers and the lake are among the richest in fish of all African waters. The humid regions also contain swarms of insects, some of which are dangerous.

Settlement patterns. Conditioned by soil and climate, land is put to different uses in the three vegetation zones. In the wet and dry tropical zone, farmers cultivate rice and sorghum in the clay soils and peanuts (groundnuts) and millet in the sandier areas. Manioc, recently introduced,

Shostal Associates/Superstock

The village of Korbo, in south central Chad.

is also cultivated. Between the latitudes of 11° and 15° N, the retreat of the rivers in the dry season leaves behind flooded depressions called *yaere,* allowing a second crop of "dry season" sorghum, or *berbere,* to be cultivated. Since 1928 the cultivation of cotton in the area between the Logone and Chari rivers has been encouraged, first by the colonial administration and since 1960 by the national government. Cotton cultivation, while tending to upset the ecological balance by exhausting the soil, has nevertheless resulted in the introduction of a cash economy in place of a barter economy. The cultivation of rice, begun in 1958 in irrigated plots in the Bongor region, south of N'Djamena, has proved successful. A joint venture with France introduced sugarcane cultivation in the 1970s. Improved strains of both cotton and rice have produced higher yields.

The intermediate semiarid tropical zone is inhabited by both sedentary cultivators and nomadic pastoralists. The northern limit of the bloodsucking tsetse fly, deadly to cattle and the carrier of sleeping sickness to humans, is latitude 10° N; beyond this limit, extensive stock raising begins, occasionally in association with agriculture, as for example in the Kanem region. The inhabitants raise millet and grow peanuts wherever the mean annual rainfall exceeds 15 inches. Cotton is grown where and when rainfall exceeds 30 inches. Large herds of cattle migrate over the semiarid tropical zone in search of pasture and water. In very limited areas bordering Lake Chad, the presence of water allows three harvests of wheat and corn (maize) to be grown in some years on irrigated plots called polders. Elsewhere the seminomadic inhabitants are almost completely dependent upon rainfall. Drought has had serious repercussions, affecting both the livestock and the pastoralists, whose livelihood depends on milk products.

In the hot arid zone, nomads live among their herds of camels, frequenting palm groves in such oases as that at Largeau. Farther north, in the Tibesti Mountains, tiny plots of millet, tomatoes, peppers, and other minor crops are grown for local consumption, often in the shade of date palms. These garden crops depend on irrigation from springs breaking out from the sandstones and volcanic rocks at widely separated points and shallow wells in the sandy sediments flooring steep-sided valleys.

Urban life
Urban life in Chad is virtually restricted to the capital, N'Djamena. Founded in the early years of the 20th century, the city has undergone a dramatic growth in population due not to a high degree of industrialization but to the other attractions of urban life. The majority of the population is engaged in commerce. Other major towns, such as Sarh (formerly Fort-Archambault), Moundou, and Abéché, are less urbanized than is the capital.

The people. The population of Chad presents a tapestry composed of different languages, peoples, and religions that is remarkable even amid the variety of Africa. The degree of variety encountered in Chad underscores the significance of the region as a crossroads of linguistic, social, and cultural interchange.

Linguistic groups. More than 100 different languages and dialects are spoken in the country. Although many of these languages are imperfectly recorded, they may be divided into the following 12 groupings: (1) the Sara-Bongo-Bagirmi group, representing languages spoken by about one million people in southern and central Chad, (2) the Mundang-Tuburi-Mbum languages, which are spoken by several hundred thousand people in southwestern Chad, (3) the Chado-Hamitic group, which is related to the Hausa spoken in Nigeria, (4) the Kanembu-Zaghawa languages, spoken in the north, mostly by nomads, (5) the Maba group, spoken in the vicinity of Abéché and throughout the Ouaddaï region of eastern Chad, (6) the Tama languages, spoken in the Abéché, Adré, Goz Béïda, and Am Dam regions, (7) Daju, spoken in the area of Goz Béïda and Am Dam, (8) some languages of the Central African groups, particularly Sango (also the lingua franca of the Central African Republic), which are spoken in the south, (9) the Bua group, spoken in southern and central Chad, (10) the Somrai group, spoken in western and central Chad, and (11) Mimi and (12) Fur, both spoken in the extreme east.

In addition to this rich assortment, Arabic is also spoken in various forms and is one of the two official languages of the country. The dialects spoken by the nomadic Arabs differ from the tongue spoken by settled Arabs. A simplified Arabic is spoken in towns and markets; its diffusion is linked to that of Islām.

French is the other official language, and it is used in communications and in instruction as well, although the national radio network also broadcasts in Arabic, Sara Madjingay, Tuburi, and Mundang. While a regional form of French, showing local linguistic and environmental peculiarities, is spoken widely in the towns, its penetration into the countryside is uneven. Its use is closely linked to the development of education.

Ethnic groups. As might be expected, the linguistic variety reflects an ethnic composition of great complexity. A general classification may nevertheless be made, again in terms of the three regions of Chad.

In the wet and dry tropical zone, the Sara group forms a significant element of the population in the central parts of the Chari and Logone river basins. The Laka and Mbum peoples live to the west of the Sara groups and, like the Gula and Tumak of the Goundi area, are culturally distinct from their Sara neighbours. Along the banks of the Chari and Logone rivers, and in the region between the two rivers, are found the Tangale peoples.

Peoples of the semiarid tropical zone
Among the inhabitants of the semiarid tropical zone are the Barma of Bagirmi, the founders of the kingdom of the same name; they are surrounded by groups of Kanuri, Fulani, Hausa, and Arabs, many of whom have come from outside Chad itself. Along the lower courses of the Logone and Chari rivers are the Kotoko, who are supposedly descended from the ancient Sao population that formerly lived in the region. The Yedina (Buduma) and Kuri inhabit the Lake Chad region and, in the Kanem area, are associated with the Kanembu and Tunjur, who are of Arabic origin. All of these groups are sedentary and coexist with Daza, Kreda, and Arab nomads. The Hadjeray (of the Guera Massif) and Abou Telfàn are composed of refugee populations who, living on their mountainous terrain, have resisted various invasions. On the plains surrounding the Hadjeray are the Bulala, Kuka, and the Midogo, who are sedentary peoples. In the eastern region of Ouaddaï live the Maba, among whom the Kado once formed an aristocracy. They constitute a nucleus surrounded by a host of other groups who, while possessing their own languages, nevertheless constitute a distinct cultural unit. The Tama to the north and the Daju to the south have formed their own separate sultanates. Throughout the Ouaddaï region are found groups of nomadic Arabs, who are also found in other parts of south central Chad. Despite their widespread diffusion, these Arabs represent a single ethnic group composed of a multitude of tribes. In Kanem other Arabs, mostly of Libyan origin, are also found.

In the northern Chad regions of Tibesti, Borkou, and Ennedi the population is composed of black nomads. Their dialects are related to those of the Kanembu and Kanuri.

Religious groups. The great majority of Muslims are found in the north and east of Chad. Islāmization in Kanem came very early and was followed by the conversion to Islām of the major political entities of the region, such as the sultanates of Wadai, Bagirmi, and Fitri, and—more recently—the Saharan region. Islām is well established in most major towns and wherever Arab populations are found. It has attracted a wide variety of ethnic groups and has forged a certain unity which, however, has not resulted in the complete elimination of various local practices and customs.

Animism flourishes in the southern part of the country and in the mountainous regions of Guera. The various traditional religions provide a strong basis for cohesion in the villages where they are practiced. Despite a diversity of beliefs, a widespread common feature is the socioreligious initiation of young people into adult society.

In Chad, as elsewhere, Christian missionary work has not affected the Muslim population; it has been directed toward the animist populations in the cities in the western regions south of the Chari River and in parts of the central uplands area. There are three Roman Catholic dioceses,

with an archbishop at N'Djamena. There are some Protestant mission groups, and an effort has been made to form a Chad Evangelical church.

Demographic trends. More than two-fifths of the population of Chad are under the age of 15. Nearly one-fourth of the people are considered to be urban dwellers, the majority living in N'Djamena. The population is increasing at a comparatively low rate for an African country. Emigration—especially to The Sudan, Nigeria, and northern Cameroon—resulting from drought, conflict, and famine, may help to account for this.

The economy. *Resources.* Chad's principal mineral resource is natron (a complex sodium carbonate), which is dug up in the Lake Chad and Borkou areas and is used as salt and in the preparation of soap and medicines. Annual production is a few thousand tons. There are indications of deposits of gold in the Ouaddaï area, uranium in the Ennedi Plateau area, uranium and wolframite in the Aozou Strip in the far north, and bauxite near Laï. Oil has been found north of Lake Chad.

Agriculture and fishing. Cotton is Chad's primary product. Although it is basically an export crop, the processing of raw cotton provides employment for a majority of those in industry and accounts for most of Chad's export earnings. Most of the cotton fibre ginned in Chad's processing plants is exported to Europe and the United States.

Importance of livestock

Chad's livestock constitutes its second most important economic resource and is primarily distributed across central Chad. Much of this wealth is not reflected in the national cash economy, however, and livestock products form less than one-tenth of exports. There is a refrigerated meat-processing plant at Sarh, which exports meat to the Congo and Gabon. The government has tried to improve livestock by introducing stronger breeds and production by building new slaughterhouses.

Rice is produced in the Chari valley and in southwestern Chad, and wheat is grown along the shores of Lake Chad; little of either crop is processed commercially.

About half the fish caught is salted and dried for export. Most fish are caught in the Lake Chad, Chari, and Logone basins.

Industry. The development of industry is hampered by a shortage of power. Energy is generated by using oil products imported from Nigeria. The primary industries, such as cotton ginning, slaughtering, and the milling of wheat and rice, are all associated with agriculture. Secondary industries are few and rely on imported materials.

Finance and trade. The country relies heavily on foreign financial assistance. The sums received exceed export earnings and in many years constitute as much as a quarter of the gross national product. The main imports are petroleum products, partly from Nigeria, plus cereals and manufactured articles, above all from France. Raw cotton is by far the main export, the amount varying annually from about 80,000 to 150,000 tons. In addition, live cattle, meat, and fish are exported to Nigeria.

Transportation. Chad's economic development is primarily contingent upon the establishment of an effective transportation network. There are three access routes to the sea—by road, river, or rail, through neighbouring countries. Most of the country's roads and trails are impractical for travel during part of the rainy season. Year-round traffic is possible on gravel-surfaced roads and on a paved section between N'Djamena and Guélendeng. Three major road axes, forming a triangle joining N'Djamena, Sarh, and Abéché, were completed but have fallen into disrepair. In 1985 a bridge across the Chari River to Kousseri, Cameroon, ended N'Djamena's dependence on an unreliable ferry for its road connection through Cameroon to the railhead at Ngaoundéré and the sea.

Rivers are of secondary importance due to great seasonal fluctuations in water levels, with only about half of the total river length navigable year-round. The Chari is navigable between Sarh and N'Djamena between August and December, and the Logone is navigable between Mondou and N'Djamena in September and October. Two railways have their terminals near the Chad border. Across the Nigerian frontier to the west there is a railhead at Maiduguri, which links up with the Nigerian ports of Lagos and

Port Harcourt. Across the Sudanese frontier to the east is the railhead at Nyala, which leads eventually to Port Sudan on the Red Sea. Air traffic plays an important role in the Chad economy, in view of the paucity of alternative means. N'Djamena's airport can accommodate large jets, and there are more than 40 secondary airports.

Administration and social conditions. *Government.* The constitution of 1975 was replaced by the *charte fondamentale* in 1978, and this in turn was abolished in 1979. In 1982, pending the adoption of a new constitution, the provisional *acte fondamental* was instituted. It assigned full powers to the president. The government consists of a Council of Ministers and the National Consultative Assembly, an advisory body consisting of two representatives from each of the country's 14 *préfectures,* plus two representatives from the capital, all appointed by the president. The new constitution was adopted in 1989.

Civil war broke out in the mid-1960s when two guerrilla groups struggled to overthrow the government and create closer ties with Arab North Africa. Internal struggles and conflict with Libya continued throughout the 1980s.

Education. The size of the country, the dispersion of populations, and the occasional reluctance to send children to school all constitute educational problems that the government is endeavouring to overcome. Less than one-half of the school-age population is enrolled. Missions and public education services are responsible for primary education. Secondary and technical education is also available. The University of Chad, founded in 1971, offers higher education, and some Chad students study abroad.

Health and welfare. There are major hospitals at N'Djamena, Sarh, Moundou, Bongor, and Abéché. Other health facilities include dispensaries and infirmaries dispersed throughout the country. The government, in cooperation with the World Health Organization, has developed a health education and training program. Campaigns have been conducted against malaria, sleeping sickness, leprosy, and other diseases.

Cultural life. With its rich variety of peoples and languages, Chad possesses a valuable cultural heritage. The government has in the past encouraged cultural activities and institutions. There is a national museum of prehistoric and traditional artifacts. The Chad Cultural Centre seeks to awaken a conscious interest in national traditions. The lives of the people have been so dislocated by war and famine since the 1960s, however, that Chad is more impoverished than ever, and the main efforts of the government and people are now directed toward survival.

For statistical data on the land and people of Chad, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.   (A.T.G.)

HISTORY

The region of the eastern Sahara and Sudan from Fezzan, Bilma, and Chad in the west to the Nile valley in the east was well peopled in Neolithic times, as discovered sites attest. Probably typical of the earliest populations were the Negroid cave dwellers described by Herodotus as inhabiting the country south of Fezzan. The ethnographic history of the region is that of gradual modification of this basic stock by the continual infiltration of nomadic and increasingly Arabicized white African elements, entering from the north via Fezzan and Tibesti and, especially after the 14th century, from the Nile valley via Darfur. According to legend, the country around Lake Chad was originally occupied by the Negroid Sao. This vanished people is probably represented today by the Kotoko, in whose country, along the banks of the Logone and Chari, was unearthed in the 1950s a medieval culture notable for work in terra-cotta and bronze.

The relatively large and politically sophisticated kingdoms of the central Sudan were the creation of Saharan Berbers, drawn southward by their continuous search for pasturage and easily able to impose their hegemony on the fragmentary indigenous societies of Negroid agriculturalists. This process was intensified by the expansion of Islām. There are indications of a large immigration of pagan Berbers into the central Sudan early in the 8th century.

From the 16th to the 19th century. The most important

of these states, Kanem-Bornu, which was at the height of its power in the later 16th century, owed its preeminence to its command of the southern terminus of the trans-Saharan trade route to Tripoli.

Products of the Islâmized Sudanic culture diffused from Kânem were the kingdoms of Bagirmi and Ouaddaï, which emerged in the early years of the 17th century out of the process of conversion to Islâm. In the 18th century the Arab dynasty of Ouaddaï was able to throw off the suzerainty of Darfur and extend its territories by the conquest of eastern Kanem. Slave raiding among the followers of traditional religion to the south constituted an important element in the prosperity of these Muslim states. In the 19th century, however, they declined, torn by wars and internecine feuds. In the years 1883–93 they all fell to the Sudanese adventurer Râbiḥ az-Zubayr.

The 20th century. By this time the partition of Africa among the European powers was entering its final phase. Râbiḥ was overthrown in 1900, and the traditional Kanembu dynasty was reestablished under French protection. Chad became part of the federation of French Equatorial Africa in 1910. The pacification of the whole area of the present republic was barely completed by 1914, and between the wars French rule was unprogressive. A pact between Italy and France that would have ceded the Aozou Strip to Italian-ruled Libya was never ratified by the French National Assembly, but it provided a pretext for Libya to seize the territory in 1973. During World War II Chad gave unhesitating support to the Free French cause. After 1945 the territory shared in the constitutional advance of French Equatorial Africa. In 1946 it became an overseas territory of the French Republic.

Independence. A large measure of autonomy was conceded under the constitutional law of 1957, when the first territorial government was formed by Gabriel Lisette, a West Indian who had become the leader of the Chad Progressive Party (PPT). An autonomous republic within the French Community was proclaimed in November 1958, and complete independence in the restructured community was attained on Aug. 11, 1960. The country's stability was endangered by tensions between the black and often Christian populations of the more economically progressive southwest and the conservative, Muslim, nonblack leadership of the old feudal states of the north, and its problems were further complicated by Libyan involvement.

Lisette was removed by an associate more acceptable to some of the opposition, N'Garta (François) Tombalbaye, a southern trade union leader, who became the first president of the republic. In March 1961 Tombalbaye achieved a fusion of the PPT with the principal opposition party, the National African Party (PNA), to form a new Union for the Progress of Chad. An alleged conspiracy by Muslim elements, however, led in 1963 to the dissolution of the National Assembly, a brief state of emergency, and the arrest of the leading ministers formerly associated with the PNA. Only government candidates ran in the new elections in December 1963, ushering in the one-party state.

(D.H.J./A.T.G.)

Civil war. In the mid-1960s two guerrilla movements emerged. The Front for the National Liberation of Chad (Frolinat) was established in 1966 and operated primarily in the north from its headquarters at the southern Libyan oasis of al-Kufrah, while the smaller Chad National Front (FNT) operated in the east central region. Both groups aimed at the overthrow of the existing government, the reduction of French influence in Chad, and closer association with the Arab states of North Africa. Heavy fighting occurred in 1969 and 1970, and French military forces were brought in to suppress the revolts.

By the end of the 1970s, civil war had become not so much a conflict between Chad's Muslim northern region and the black southern region as a struggle between northern political factions. Libyan troops were brought in at President Goukouni Oueddei's request in December 1980 and were withdrawn, again at his request, in November 1981. In a reverse movement the Armed Forces of the North (FAN) of Hissen Habré, which had retreated into The Sudan in December 1980, reoccupied all the important towns in eastern Chad in November 1981. Peace-

keeping forces of the Organization of African Unity withdrew in 1982, and Habré formed a new government in October of the same year. Simultaneously, an opposition government under the leadership of Goukouni was established, with Libyan military support, at Bardaï in the north. After heavy fighting in 1983–84 Habré's FAN prevailed, aided by French troops. France withdrew its troops in 1984 but Libya refused to do so. Libya launched incursions deeper into Chad in 1986, and they were turned back by government forces with help from France and the United States.

In early 1987 Habré's forces recovered the territory in northern Chad that had been under Libyan control and for a few weeks reoccupied Aozou. When this oasis was retaken by Muammar al-Qaddafi's Libyan forces, Habré retaliated by raiding Maaten es Sarra, which is well inside Libya. A truce was called in September 1987. Habré continued to face threats to his regime. In April 1989 an unsuccessful coup attempt was led by the interior minister, Brahim Mahamot Itno, and two key military advisers, Hassan Djamouss and Idriss Déby. Itno was arrested and Djamouss was killed, but Déby escaped and began new attacks a year later. By late 1990 his Movement for Chadian National Salvation forces had captured Abéché, and on December 1 Habré fled to Cameroon. Déby suspended the constitution and formed a new government with himself as president. He became the elected president in 1996 and was reelected in 2001, although dissident factions continued to create problems.

For later developments in the history of Chad, see the BRITANNICA BOOK OF THE YEAR. (A.T.G.)

The Gambia

The Gambia is a small republic with an area of 4,127 square miles (10,689 square kilometres). Essentially, The Gambia is a strip of land 15 to 30 miles (25 to 50 kilometres) wide and 295 miles long on either bank of the Gambia River; except for a short coastline, it is surrounded by Senegal. Its unusual shape and size are attributable to territorial compromises arising from 19th-century Anglo-French rivalry in western Africa. The capital of The Gambia is Banjul.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* The Gambia River is the country's dominant feature, flowing across a plateau of Miocene-Pliocene sandstone, compacted sediment composed predominantly of quartz grains formed from 23.7 to 1.6 million years ago. In the east, narrow valleys are separated by broad interfluves or flattish hills. In the west, lower and smaller sand hills alternate with depressions filled in with sand so that a flat plain is formed.

Climate. The climate is of the drier tropical type, characterized by a short and intense rainy season occurring between June and October and by a longer dry season. Near the coast the rainy season lasts longer and the rainfall is heavier, diminishing eastward. At Yundum the average annual rainfall is about 51 inches (1,300 millimetres) and the mean monthly temperature is 77° F (25° C), while at Basse Santa Su, about 270 miles inland, the comparable figures are 43 inches and 82° F (28° C). The relative humidity is high but drops from December to April, when the dry northeastern wind known as the harmattan is dominant.

Plant and animal life. The vegetation cover of The Gambia is savanna on the uplands, various kinds of inland swamp in the low-lying areas, and mangrove swamp along the brackish lower Gambia River. Few wild animals are native to the region, and those that survive are under pressure from the human and domestic animal populations. In the middle and upper river areas there are warthogs, monkeys, baboons, antelope, pygmy hippopotamuses, and crocodiles.

Settlement patterns. Patterns of settlement in The Gambia reflect three regions, expressed on both banks of the river, consisting of (1) the swamps adjacent to the river (and not extending above Kau-Ur), (2) the riverine flats, known as *banto faros* (from a Malinke word meaning "beyond the swamp"), and (3) the sandstone uplands. Most

rural settlement is concentrated on the uplands, which have the best-drained soils. A number of settlements are located in the *banto faros* on the middle course of the river, where there is less danger of flooding than in the swamps. Many villages are built on the boundary between the uplands and the riverine flats.   (E.R.A.F./H.A.G.)

The people. The river basin was a focal point for migrating groups of people escaping the turmoil of western Sudanic wars dating from the 12th century. The Diola (Jola) are the people longest resident in the country; they are now located mostly in western Gambia. The largest group is the Malinke, comprising about two-fifths of the population. The Wolof, who are the dominant group in Senegal, also predominate in Banjul. The Fulani settled the extreme upriver areas. The Soninke, an admixture of Malinke and Fulani, are also concentrated in the upriver areas. The population is mainly Muslim.

The economy. *Agriculture.* The Gambia's economy is heavily reliant on agriculture, which though producing some one-fifth of the country's gross domestic product, *Importance* employs a large majority of the workforce. Peanuts *of peanuts* (groundnuts) are the most valuable agricultural commodity. Land is cleared by the slash-and-burn technique, but farmers practice conservation. Most land is held in common by the villagers. There is a sharp division of labour, with men involved in planting, cultivating, and harvesting cash crops. Women cultivate subsistence crops such as cassava, yams, eggplant, tomatoes, and lentils.

In order to diversify the economy, the government has encouraged the production of rice, and a pilot scheme was begun in the mid-1960s to introduce plantation oil palm production, but this has had little impact on the national economy. Stock farming, always a factor in the Fulani culture, has also received government support, but the scarcity of suitable pasture has kept herds small.

Fishing. Although the country's small ocean coastline limits marine fishing, there is some potential for commercial fishing offshore and in the river. The government has loaned small amounts for the purchase of motorized fishing boats and the construction of smoke huts for the processing of *bonga* (shad, or West African herring), which is exported to other western African states.

Industry. The only significant industry in the country is peanut processing. The crop is sold to agents of the Gambia Produce Marketing Board, which fixes the season's price in advance, pays the producers in cash, and sells the crop overseas. Handicraft and other small-scale, local craft production exist in villages throughout the country.

Tourism has grown in importance and is a major source of foreign exchange. Tourism declined after the 1994 coup but had begun to revive by the end of the 1990s. Several luxury hotels have been built near Banjul.

Trade and finance. The Gambia previously had a relatively large volume of trade for such a small country. In the early 1980s, however, the country had a yearly adverse

balance of trade reflecting the losses caused by the drought. The trade deficit continued into the 1990s and has been increasing annually. Besides peanuts, exports include cotton, rice, and cattle. The smuggling of peanuts into Senegal is common and often accounts for a major portion of The Gambia's export trade. All manufactured items must be imported; other imports include petroleum products, lumber, and cement. The Gambia is highly dependent on foreign aid, especially from Britain.

Transportation. The Gambia River has historically been the chief route between the interior and the coast, but a modern all-weather road now reaches the eastern border and parallels the river on both sides. Ferries cross the river at Banjul and at other points, as there are no bridges across the river, and small watercraft are common. There are no railways and no domestic air services, although an international airport is nearby at Yundum. The main port is at Banjul.

Administration and social conditions. *Government.* A new constitution went into effect in 1997. It provides for a 49-member National Assembly, which holds legislative *The 1997* power. The president, who is head of the government, is *constitu-* elected by universal suffrage to a five-year term. The vice *tion* president and cabinet members are appointed by the president from among the elected members of the assembly. The highest judicial body is the Supreme Court, and there are also Shari'ah courts, which hear cases on Islāmic law.

Education. Education at the primary level is free but not compulsory. There are secondary and postsecondary schools, including a teacher-training college at Brikama. Education has been a priority of the current government, and the government is in the process of establishing its first university. Gambian students seeking higher education must leave the country.

Health and welfare. Health-care facilities tend to be centred around Banjul. There is virtually no modern health care in the rural areas, although the Medical Research Council at Fajara investigates tropical diseases. Overall medical conditions in The Gambia are poor. The population's birth and death rates and the rate of infant mortality are average for western Africa but high by world standards, as is the average life expectancy.

Cultural life. Dance and music, traditionally tied to village activities, remain important. Praise songs are part of the repertoire of musicians called *griots,* whose art preserves oral cultural and historical traditions. Gambians are enthusiastic soccer (association football) fans. Other popular sports include basketball, track and field, and cricket. Traditional wrestling is especially popular throughout the country. The government-operated *News Bulletin* circulates mainly in Banjul. Radio Gambia, also government-run, broadcasts in various European and Gambian languages. Access to television in The Gambia is limited.
                                                        (E.R.A.F./H.A.G./Ed.)

For statistical data on the land and people of The Gambia, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

Ox-drawn equipment used for plowing in The Gambia.

HISTORY

Precolonial history. Gambian history before the arrival of Europeans is speculative. The Malinke and Wolof kingdoms, fully established by the 19th century, were still in the formative stages when the Portuguese explorer Alvise Ca' da Mosto (Cadamosto) arrived in 1455. The Malinke were the westernmost peoples of the old Mali empire. The Wolof probably migrated from the Songhai regions, and the Fulani pastoralists were part of a migration from the Futa Toro. Although locally powerful, none of the small Gambian kingdoms were ever strong enough to dominate Senegambia. Continuing internecine warfare made it easy for the French and British to dominate the territory.

European colonization. The first Europeans in the Gambia, the Portuguese, established trading stations in the late 1400s but abandoned them within a century. Trade possibilities in the next two centuries drew English, French, Dutch, Swedish, and Courlander trading companies to western Africa.

The 18th century witnessed a struggle for prestige in Senegambia between France and England. Trade was min-

imal, and no chartered company made a profit. French and British outposts changed hands a number of times. Britain controlled the entire area between 1763 and 1783, but the Treaty of Versailles returned all French possessions. British presence on the river was maintained until 1823 by individual traders.

The founding of Bathurst

Captain Alexander Grant was sent to the Gambia in 1816 to reestablish a base from which the navy could operate to control the slave trade. He purchased Banjul Island (St. Mary's) from the king of Kombo, built barracks, laid out a town, and set up an artillery battery to control access to the river. The town, Bathurst (now Banjul), grew rapidly with the arrival of traders and workers from Gorée and upriver. The Gambia was administered as a part of the British West African Federation from 1821 to 1843. It was a separate colony with its own governor until 1866, when control was returned to the governor-general at Freetown until 1889.

British domination of the riverine areas seemed assured after 1857, but the increasing importance of peanut cultivation in Senegal prompted a new imperialism. By 1880 France controlled Senegal; in the 1870s the British attempted twice to trade the Gambia to France, but opposition at home and in the Gambia foiled these plans. Complicating matters was the series of religious conflicts, called the Soninke-Marabout Wars, lasting a half century. Only one Muslim leader, Maba, emerged who could have unified the various kingdoms, but he was killed in 1864. By 1880 the religious aspect had all but disappeared, and the conflicts were carried on by war chiefs such as Musa Mollah, Fodi Silla, and Fodi Kabba.

British protectorate. A Paris conference in 1889 obtained French agreement to British control of the Gambia River and the drawing of the present-day boundaries. In 1900 Britain imposed indirect rule on the interior, or protectorate (established in 1894), areas, dividing the Gambia into 35 chiefdoms, each with its own chief. The real power, however, was concentrated in the governor and his staff at Bathurst.

Except for some trouble with slave-raiding chiefs, the Gambia enjoyed peace after its separation from Sierra Leone. In 1906 an ordinance was passed abolishing slavery throughout the protectorate. During World War II the Gambia contributed soldiers for the Burmese campaign and was used as an air staging post. (H.A.G.)

Independence. By 1960 several political parties demanded independence, which Britain finally granted within the Commonwealth in February 1965, and The Gambia became a republic on April 24, 1970. The first president, Sir Dawda Jawara, head of the People's Progressive Party (PPP), was returned in all elections after 1972. In 1981 an attempt to overthrow the government was put down with the aid of Senegalese troops. In the aftermath, leaders of both countries created the confederation of Senegambia. This plan called for each state to retain independence of action in most areas, but military and economic resources were to be integrated. A Senegambian executive and legislature were also established, but the confederation was dissolved in 1989.

Senegambia

In July 1994 a group of young army officers, led by Captain (later Colonel) Yahya Abdul Jammeh, staged a bloodless coup, but the Senegalese government did not intervene as it had done in 1981. The military leaders ruled by proclamation, dissent was brutally repressed, and political activity was banned until August 1996. Presidential elections were held late that year, with elections for the National Assembly following in early 1997. Jammeh, now retired from the military, was elected president, and his political party, the Alliance for Patriotic Reorientation and Construction, dominated the National Assembly. A new constitution, approved by voters in 1996, came into effect after the legislative elections. The return to civilian rule improved The Gambia's international reputation, and aid organzations, which had left after the coup, began once again assisting the country. The Gambia sent peacekeeping forces into war-ravaged Liberia and has worked on improving relations with Senegal. (H.A.G./A.F.C.)

For later developments in the history of The Gambia, see the BRITANNICA BOOK OF THE YEAR.

Mali

The Republic of Mali (République du Mali) is a landlocked state in central western Africa. Bounded on the north by Algeria, on the east by Niger and Burkina Faso, on the south by Côte d'Ivoire and Guinea, and on the west by Senegal and Mauritania, it covers an area of 482,077 square miles (1,248,574 square kilometres). Bamako is the national capital. As a part of French West Africa from 1898 to its independence in 1960, it was known as the French Sudan. Its current name, taken at the time of independence, is derived from the Mali empire of the upper and middle Niger River, which was ruled by the Malinke (Mandingo) from the 13th to the 16th century.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Mali's landscape is largely flat and monotonous. Two basic relief features can be distinguished—plateaus and plains—which are crossed by two of Africa's major river systems, the Niger and Sénégal. The highland regions are localized and discontinuous.

The plateaus of the south and southwest (extensions of the Fouta Djallon highlands of Guinea and the Guinea Highlands of Guinea and Côte d'Ivoire) lie between about 1,000 and 1,600 feet (300 and 500 metres) above sea level but attain heights approaching 2,000 feet in the Mandingue Plateau near Bamako and more than 2,100 feet near Satadougou.

The plateaus The plateaus and the plains

The plateaus of the southeast and east, also extensions of the Guinea Highlands, are a series of small, broken hills. Elevations in the southeast range between almost 1,000 feet in the region of Sikasso and 1,740 feet at Mount Mina. East of the Niger River the Dogon Plateau descends gently westward to the river valley but ends in abrupt cliffs on the southeast. These cliffs reach an elevation approaching 3,300 feet at Bandiagara.

Northern and central Mali are made up of the plains of the Niger River basin and of the Sahara. The only marked relief feature in the north is the Iforas Massif. An extension of the mountainous Hoggar region of the Sahara, this heavily eroded sandstone plateau rises to altitudes of more than 2,000 feet.

Drainage. The drainage system is composed of the Sénégal and Niger rivers and their tributaries. The Sénégal River flows in a northwesterly direction across Mali for 420 miles (670 kilometres) on its course to the Atlantic Ocean. Its main headwaters—the Bafing and the Bakoye (Bakhoy) rivers—rise in the Fouta Djallon and join at Bafoulabé to form the Sénégal. The river then flows to the west across the plateau region, where it is broken by falls at Gouina and Félou.

For 1,100 miles, more than one-third of its total length, the Niger River flows through Mali. Rising in the Fouta Djallon, the river is of significant size by the time it enters Mali near Kangaba. It flows to the northeast across the Mandingue Plateau, where it is broken by falls at Sotuba. Reaching Koulikoro, it spreads out in a wide valley and flows majestically to its confluence with the Bani River at Mopti. The Niger then forms an interior delta because the land is flat and the river's descent almost nonexistent. The river breaks down into a network of branches and lakes as it continues northward. At Bourem the Niger makes a great bend to the south, known as the Niger Bend, and flows past Gao and Ansongo to the Niger border at Labbezanga.

The flow of the Niger varies seasonally. High waters occur on the upper Niger from July to October, at the delta from September to November, and at the bend from December to January. Periodic floods and the rich alluvial soils in the central delta make the Niger valley an important agricultural region.

Soils. The soils in Mali are generally poor. In the south, ferruginous (iron-bearing) soils are shallow and form a hard, red crust because of intense evaporation. The desert region is composed of sand, rock, and gravel.

Climate. Mali lies within the intertropical zone and has a hot, dry climate. The sun is near its zenith throughout most of the year. In general, there are two distinct seasons, dry and wet. The dry season, which lasts from November

to June, is marked by low humidity and high temperatures and is influenced by the *alize* and harmattan winds. The *alize,* from the northeast from December to February, causes a relatively cold spell, with temperatures averaging 77° F (25° C). From March to June the dry, hot harmattan blows from the east out of the Sahara and sweeps the soil into dusty whirlwinds. The wind is accompanied by daytime temperatures of about 104° to 113° F (40° to 45° C).

During the rainy season from June to October, the monsoon wind blows from the southwest. Preceded by large, black clouds, the heavy rainstorms often include gusty winds and much lightning and thunder. Temperatures lessen somewhat in August, when most of the rainfall occurs.

Climatic zones

The country can be divided into three climatic zones— the Sudanic, the Sahelian, and the desert zones. Sudanic climate occurs in almost one-third of the country, from the southern border to latitude 15° N. It is characterized by an annual rainfall of 20 to 55 inches (510 to 1,400 millimetres) and average temperatures of 75° to 86° F (24° to 30° C). The Sahel, or the area bordering the Sahara, receives between eight and 20 inches of rain per year and has average temperatures between 73° and 97° F (23° and 36° C). In the Sahara, temperatures during the day may exceed 117° F (47° C), while at night the temperature often drops to 39° to 41° F (4° to 5° C).

Plant and animal life. There are two main vegetation zones that correspond to the climatic regions of the Sudan and the Sahel. In the Sudanic zone there are localized forest corridors along the Guinean border and the river valleys. The rest of the area is covered with savanna. The trees include the nere, or twoball nitta tree (*Parkia biglobosa*), the karite (*Butyrospermum parkii*), the cailcedra (Senegal khaya; *Khaya senegalensis*), and the kapioka. The incidence of trees decreases to the north as the Sudanic zone merges with the Sahel. The Sahel is characterized by steppe vegetation; drought-resistant trees such as the baobab, the doum palm, and palmyra are found. These trees also disappear to the north, however, where short, thorny plants such as the mimosa, acacia, and *cram-cram* (*Cenchrus biflorus,* a member of the grass family) occur. All vegetation gradually disappears as one enters the Sahara region.

The animal life of the Sudan and of the Sahel is rich and varied. Large, herbivorous mammals include gazelles, antelopes, giraffes, and elephants. The main carnivores are lions, panthers, and hyenas. Crocodiles and hippopotamuses inhabit the rivers, and there is a wide variety of monkeys, snakes, and birds (including the ostrich). Boucle du Baoulé National Park along the Baoulé River in the west and an animal reserve between Ansongo and Ménaka in the east are major wildlife sanctuaries.

Settlement patterns. Mali is traditionally divided into the nomadic region of the Sahel and the Sahara and the agricultural region of the Sudanic zone. A declining three-fourths of the population is rural. The rural population lives in thatched dwellings grouped together in villages of between 150 and 600 inhabitants. The villages are surrounded by cultivated fields and grazing lands. The older towns, such as Djenné, Timbuktu (Tombouctou), Gao, and Ségou, are built in the characteristic Sudanese style of architecture. The newer towns, such as Bamako, Kayes, San, and Kati, consist of a central business district, around which African residential districts are grouped. The houses are built of a mixture of earth and cement.

The people. *Ethnic groups.* Ethnicity is fluid in Mali. Some people marry outside their group and speak different languages without changing their cultural affiliation. In other cases, however, identity does change, especially as people move and adopt Bambara, the most widely spoken African language in Mali, but some broad categories can be noted. Living in the Sahelian zone and north of the Niger Bend are Berbers (including the Tuareg, a significant subgroup) and the Arab-Berber group known as the Moors, who speak and write Arabic.

Agricultural groups

The rest of the population is composed of numerous agricultural groups, some of whom are descended from the peoples of the ancient empires of Ghana, Mali, and Songhai. The Bambara, who live along the upper Niger River, make up the largest group. The Soninke are descended from the founders of the Ghana empire and live in the western Sahelian zone. The Malinke, bearers of the heritage of the Mali empire, live in the southwest, while the Songhai are settled in the Niger valley from Djenné to Ansongo. The Dogon live in the plateau region around Bandiagara, and the Bwa, Bobo, Senufo, and Minianka occupy the east and southeast.

The Fulani were traditionally nomadic pastoralists of the Sahel and the Macina region southwest of Timbuktu. Other ethnic groups of note include the Tukulor, the Khasonke, the Bozo, and the Somono. While some Tuareg and Fulani are nomadic, the vast majority of people now live in permanent settlements.

Linguistic groups. French is the official language of Mali, although Bambara is used as a lingua franca by some fourth-fifths of the population. There are many indigenous languages and dialects, which roughly correspond to either ethnic groups or regions. The largest is the Mande branch of the Niger-Congo language family, which includes Bambara, Malinke, Khasonke, Wasulunka, and Soninke. Dogon, the linguistic classification of which is still in question, includes more than 15 dialects. The languages of the Gur peoples are Bwa, Senufo, and Minianka. The Fulani and Tukulor speak Fula, and Songhai is spoken all along the Niger Bend. The Moors and the Tuareg speak and write Arabic, although the Tuareg have also retained their traditional Berber language and written script, *tifinagh.*

Religious groups. There are three main religions. Sunnite Islām is practiced by about nine-tenths of the population, traditional religions by most of the rest, and Christianity (primarily Protestantism) by a small number. Islāmization dates to the 11th century and has eclipsed traditional religions among the Soninke, Songhai, Moors, Tuareg, and most Fulani. Many of the Gur peoples, especially the Dogon, as well as some Malinke and Bambara, practice traditional African religions. Many traditional beliefs persist even among Muslim and Christian converts.

Demographic trends. The population of Mali has been growing at a rate that is higher than the world average but is comparable to the regional average. Life expectancy at birth, still comparatively low, has risen gradually since 1990 for both males and females, and there has been a slight decline in both birth and death rates, though they remain high by both world and African standards. The population is heavily weighted toward the young, as are most African populations. Population densities throughout Mali are low—in the more remote Gao and Timbuktu regions densities are only about three persons per square mile (one per square km). These have long been regions of sparse population, but the droughts of the 1970s and '80s led many of Mali's Tuareg and other groups either to migrate to the towns or, if their herds have managed to survive, to find new grazing lands farther south in Mali or in neighbouring Burkina Faso. Predictably, there has been a major increase in the permanent urban population, which now exceeds one-fourth of the population. Urban unemployment and underemployment are high, however. Less than one-fifth of the labour force is employed in industry, and many people are involved in small-scale commerce. Where opportunities exist, Malians migrate to France and other European nations for education and employment.

Growing urban population

The economy.   Mali's economy is overwhelmingly agricultural. With the northern half of the country occupied by the Sahara, most human activity is concentrated in the more southerly regions, in particular in the valleys of the Niger and Sénégal rivers and their tributaries. Subsistence agriculture and livestock raising characterize domestic activities, although many people supplement their income by growing cash crops such as cotton and by seasonal migration to Côte d'Ivoire and Senegal. Change in the rural sector has been limited by an unfavourable climate, periodic droughts since the late 1960s, and low levels of technology.

The industrial and natural resource sectors have not been developed fully. Industry concentrates largely on food processing for domestic use, while advancement in the exploitation of extensive mineral resources is slow.

Foreign exchange is obtained chiefly from the export of primary commodities that are vulnerable to volatile world markets and foreign currency fluctuations. Revenue is insufficient to cover the cost of Mali's imports, notably the

Marketplace at Djenné, Mali.
© Brian A. Vikander—West Light

high-value goods from France and other Western nations. In addition to its other problems, Mali has suffered severely from resource mismanagement, and the national debt has grown rapidly because of Mali's high dependency on foreign aid.

At the time of independence in 1960, the government adopted a socialist economic policy. State companies and rural cooperative societies were organized to regulate both the production and the distribution of goods. Since the first coup d'état in 1968, socialist policy has been mitigated by the encouragement of privatization, a process that has accelerated since the institution of democracy in 1992.

Mali's form of socialism

Bilateral external aid to Mali is provided largely by France, the United States, other European Union nations, and the nations of OPEC. International aid is granted by such organizations as the UN, the European Development Fund, and the United Nations Development Programme. Since 1981 the Mali government has responded to pressures from the World Bank, the International Monetary Fund, and aid donors to encourage private investment and enterprise, liberalization of domestic markets, and the general reduction of state control.

Resources. Mali's natural resources remain relatively undeveloped. Iron is the most widespread mineral resource, but it is not currently exploited because of Mali's limited infrastructure. Deposits are found in the west near the Senegal and Guinea borders. Bauxite deposits are located near Kayes and on the Mandingue Plateau. Manganese is also found, and there are phosphate deposits in the Ansongo region.

Important deposits of gold are at Kalana near Bougouni, on the Mandingue Plateau, and in the Iforas Massif. Lithium has been discovered near Kayes and Bougouni, and there are uranium deposits in the Iforas. There are also traces of tungsten, tin, lead, copper, and zinc, as well as deposits of salt, marble, kaolin (china clay), and limestone.

Agriculture and fishing. Subsistence and commercial agriculture are the bases of the Malian economy. Roughly four-fifths of the working population is in subsistence agriculture, and the government supports the development of commercial products. Areas of cultivation are located in the Sudanese and Sahelian zones; an agricultural area of major importance is the inland Niger delta. Crops such as millet, rice, wheat, and corn (maize), as well as potatoes, yams, and cassava, are the main subsistence crops. Cotton and peanuts (groundnuts) are the important commercial crops; sugarcane, tobacco, and tea are also grown for market. Market gardens produce a variety of vegetables and fruits, including cabbages, turnips, carrots, beans, tomatoes, bananas, mangoes, and oranges. Irrigation projects have been developed on the Niger near the towns of Ségou and Mopti. The major areas for the raising of livestock (cattle, sheep, and goats) are the Sahel and the area around Macina.

Agricultural products

Mali is one of the largest producers of fish in western Africa. The inland delta is a particularly important fishing ground, though the drought has caused a major setback to the industry.

Industry. The mining industry is little developed. Exploited deposits are those of salt (at Taoudenni), marble and kaolin (at Bafoulabé), gold (at Kalana), and limestone (at Diamou). The export of gold, however, is a significant source of foreign exchange. Most manufacturing enterprises process food and other agricultural products or make consumer goods, the bulk of production being for the domestic market.

The Malian Company of Textiles (Comatex) produces cotton fibre and cloth, while the Textile Industry of Mali (Itema) manufactures printed cloth and blankets. There are also shops for the construction of motorcycles, the repair of machinery, and the assembly of radios. Handicrafts are important, and the Malians are noted for their clothing, pottery, shoes, baskets, and wood carvings.

Handicrafts

Electricity is largely produced in thermal power stations, but the role of hydroelectric power is growing. Thermal stations are located in Bamako and other large towns. Hydroelectric power is produced at the Sotuba and Markala dams on the Niger River, at the Felou Dam on the Sénégal River, and at the Sélingué Dam on the Niger near Bamako. The Manantali Dam on the Sénégal, a joint venture with Senegal and Mauritania largely completed in 1988, has substantially boosted generating capacity. Mali has also begun to exploit solar energy; solar-powered pumps provide electricity to some 30 villages, and the world's first commercial solar power station was established at Diré.

Finance and trade. The Central Bank of Mali, managed jointly by Mali and France, controls the nation's credit and the exchange rate between the CFA (Communauté Financière Africaine) franc and the French franc. The Development Bank of Mali finances development projects, while the Malian Bank of Credit and Deposits and the French-owned West African International Bank carry out credit and depository functions. Several French insurance companies maintain offices in Bamako.

The most important export items are cotton, live animals, and gold, while imports consist largely of machinery, appliances, and transport equipment and food products. Mali's major trading partners are the countries of the European Union and Côte d'Ivoire. It is a member of the Organization for the Development of the Sénégal River, which also includes Senegal and Mauritania. Despite strict customs controls, smuggling—especially of cattle and fish—is considerable, especially to such neighbouring countries as Mauritania and Côte d'Ivoire.

Transportation. Mali's transportation systems are concentrated in the Sudanic and Sahelian regions. Because Mali is landlocked, its major transport routes connect with those of neighbouring countries and their ports to provide it with outlets to the sea.

There are several main axes of paved roads radiating from Bamako. The road from Bamako to Bougouni and Sikasso connects with the Côte d'Ivoire road running to the port of Abidjan. A road links Bamako with Kankan in Guinea and Monrovia in Liberia. Another main road runs through Bamako, Ségou, San, Mopti, Gao, and Ansongo to the border with Niger. Construction of a trans-Saharan road connecting Gao with North Africa was begun in 1979.

The one railroad track runs from Koulikoro, a short distance northeast of Bamako, northwestward to Kayes and to Kidira, on the Senegal border, where it connects with the Senegalese railway to Dakar. These railways are being restored and modernized through donor-funded programs.

Given the inadequacies of land transport, the two major rivers—the Sénégal and the Niger—are important transportation links. The Niger is navigable throughout its length in Mali from July to January. The Sénégal, currently navigable only from July to October from Kayes to the west of the country to the river's mouth in Senegal, should provide year-round transportation once all parts of the Manantali Dam project are completed.

A national airline, Air Mali, operates both domestic and international flights, but its unreliable service is frequently canceled for weeks at a time. Mali's main airport is at Bamako, and there are several other smaller ones. Bamako is also linked by air to France, Morocco, and other western African nations.

Administration and social conditions. *Government.* The constitution promulgated at independence in 1960 guaranteed parliamentary democracy, although the provisions of it were not fully implemented. It was suspended after a military government took power in 1968, and a new constitution, approved in a national referendum in 1974 and enacted in 1979, made the Mali People's Democratic Union (Union Démocratique du Peuple Malien; UDPM) the country's sole legal party until 1991. In 1992 a third constitution was approved, providing for the separation of powers into three government branches, including a unicameral National Assembly as the legislative body, and the right to multiparty politics. The 147 members of the assembly are popularly elected to five-year terms, as is the president. The president, who can serve no more than two terms, is the head of state and appoints the prime minister (the head of government) and the cabinet.

The country is divided into the seven *régions* of Kayes, Koulikoro, Sikasso, Ségou, Mopti, Gao, and Timbuktu and the district of Bamako. Each of the *régions* is further divided into administrative units called *cercles* ("circles"), which are in turn subdivided into smaller units called *arrondissements.* Each *région* is administered by a governor, who coordinates the activities of the *cercles* and implements economic policy. The *cercles* provide nuclei for the major government services; their various headquarters provide focal points for the health service, the army, the police, local courts, and other government agencies. The *arrondissement* is the basic administrative unit, and its centre usually houses a school and a dispensary.

Justice. At the head of the judicial system, the Supreme Court exercises both judicial and administrative powers; it is the court of first and last resort in matters concerning the government. The Court of Appeal, located in Bamako, tries all cases on appeal from ordinary tribunals. The Special Court of State Security holds trials for crimes against state property, especially concerning itself with charges of embezzlement. There are more than 50 tribunals and more than 70 magistrates. Justices of the peace have full powers to judge ordinary civil, commercial, and financial cases; they sit in the headquarters of the *cercles* and also travel to the major towns of the *arrondissements.*

Education. French is the only language of instruction. Primary and secondary education are compulsory and free from six to 15 years of age and are combined in the nine-year curriculum of the *cycle fondemental* ("fundamental educational level"). The general secondary school, or *lycée,* provides the last three years of traditional secondary education. Higher education—geared directly to the needs of the government—is obtained in state colleges. These colleges include teacher-training colleges, a college of administration, an engineering institute, a polytechnic institute, and a medical school. Many of Mali's university students study abroad, especially in France and Senegal.

Health and welfare. State hospitals at Bamako and Kati are supplemented by a network of medical centres, maternity centres, dispensaries, and a mobile service that visits patients in rural areas. Research centres in tropical ophthalmology and leprosy treat patients at Bamako. Despite improvements in medical care, child and infant mortality

rates remain among the highest in the world. While Mali has not been as hard hit by HIV as some African countries, AIDS is becoming more prevalent in urban areas.

Cultural life. Although Mali is now one of the poorest nations in the world, it has long functioned as a crossroads between northern and western Africa, thus developing a rich cultural tradition. Situated between northern and southern Africa, it has for centuries been a cultural meeting place.

The arts. The most common cultural activities involve music and dancing. Dogon dancers wear "storied house" masks that are more than 10 feet tall to act out their conception of the world's progress, and Bambara animal-spirit masqueraders do a fertility dance in which they imitate the movements of animals. Forms of these dances are most often found performed by the Malian National Folklore Troupe, founded in the 1960s. Mali also has several musicians of international repute, such as Oumou Sangare, Sali Sidibi, and Salif Keita, the last of whom is a descendant of Sundiata Keita, the founder of the Mali empire; their music combines elements of rock and roll with indigenous traditions.

The Bambara and the Gur groups excel in the creation of wood carvings of masks, statues, stools, and objects used in traditional religions. The tiewara, or gazelle mask, of the Bambara is remarkable for its fineness of line and distinct style. Architecture is well developed in the Niger valley, with building materials consisting of mud bricks, stones, and a little wood. The Sudanic style finds typical expression in the multistoried houses and mosques of Djenné and Timbuktu. Localized handicrafts include jewelry making by the Malinke people and leatherworking around the Niger Bend. Artists are trained in both traditional and contemporary genres at the National Institute of Arts and at the Artisan Centre of Bamako.

The Museum of the Institute of Research and Documentation at Bamako contains collections of art from most of the country's regions. The National Archives of Mali, the National Library, and the Institute of Human Sciences are also located in Bamako, as is the Municipal Library; a centre that preserves and collects Arabic manuscripts is located in Timbuktu.

Popular culture. Youth associations organize sports, theatrical, musical, and dancing activities. Soccer (association football) is Mali's most popular sport, and every neighbourhood in major towns has a team. Basketball is also popular, but, as in most other sub-Saharan African countries, wrestling is more prevalent. Orally transmitted epics from the ancient Malian empire speak of great wrestlers as cultural icons, and even today traditional wrestlers are held in high esteem.

The media. Mali has one newspaper, *L'Essor–La Voix du Peuple,* but its circulation is limited to the literate and effectively to Bamako. There are several commercial radio stations in addition to the national radio station, which broadcasts news bulletins, general information, and educational programs. The number of radio receivers has increased dramatically. Television was introduced in 1983 and is available in most of the country, although few Malians outside Bamako own sets. There are two stations broadcasting news, educational programs, foreign movies, and religious segments. Internet access is in its infancy in Bamako. (K.M.B./Ed.)

For statistical data on the land and people of Mali, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

Precolonial history. Rock paintings and inscriptions as well as Paleolithic and Neolithic remains have been found throughout Mali. In 1927, Neolithic human skeletal remains dating to 5000 BC were found in the Sahara at Asselar.

Rich gold deposits in the west and southwest constituted the principal resource in the economic life of early urban entrepôts and a succession of political states. An important trading centre, Djenné-Jeno, arose about 250 BC in the inland delta of the Niger River. It flourished until the 11th century AD, after which it was eclipsed by Djenné, a trad-

ing centre founded by Muslim Soninke about the 13th century AD. Terra-cotta statues, dating to as early as AD 800, have been found at Djenné-Jeno and at other sites in Mali.

The export trade in gold and in slaves, ivory, civet, and gum arabic moved over trans-Saharan caravan routes from the Niger River valley to North Africa for almost a thousand years. This trade was controlled by the Soninke kingdom of Ghana (4th–11th century), which was established between the headwaters of the Niger and Sénégal rivers.

Ghana was effectively destroyed by the Almoravid invasion of 1076, and its hegemony was ultimately assumed by the Malinke empire of Mali (12th–16th century), founded around the upper Niger. Under Mali the caravan routes moved east through Djenné and Timbuktu (founded about the 11th century AD). Mali's decline in the 15th century enabled the Songhai kingdom in the east to assert its independence. Under Songhai, Djenné and Timbuktu flourished as centres of both trade and Islāmic scholarship. In 1591 a Moroccan army of 4,000 men armed with muskets succeeded in crossing the Sahara and easily defeated the Songhai, who were armed only with bows and arrows and spears. With the destruction of Songhai hegemony, political chaos ensued, resulting in a disruption of trade.

Eventually, new trade routes in gold and slaves were established, but these were toward the coast where Europeans were establishing trading posts. The Moroccans exiled or executed the Timbuktu scholars because they represented a political threat and dispersed most of their libraries of books and manuscripts. Moroccan military and political influence never extended beyond a short stretch of the Niger in the areas of Gao and Timbuktu. Eventually, political ties between Morocco and the descendants of the Moroccan invaders lapsed. In 1737 the Moroccans were defeated by the Tuareg, who seized control of the Niger Bend. To the west the Fulani (Peul) kingdom of Macina defeated the Moroccans at Diré in 1833. West of the Fulani a powerful kingdom had been established by the Bambara at Ségou beginning in the early 17th century.

The **19th century.** Most of the 19th century was characterized by French colonial expansion from Senegal in the west and Islāmic jihads (religious wars) resulting in the establishment of theocratic states. Shehu Ahmadu Lobbo (Cheikou Amadou), a Fulani Muslim cleric, successfully overturned the ruling Fulani dynasty in Macina in 1810 and established a theocratic state whose capital was Hamdallahi. In the west, political events were dominated by al-Ḥājj 'Umar Tal, a Tukulor Muslim cleric who led a series of jihads. 'Umar conquered the Bambara kingdom of Ségou in 1861 and the Fulani empire of Macina in 1864. After 'Umar was killed in a skirmish with the Fulani in 1864, his vast domains were divided among his sons and commanders. His eldest son, Amadou Tal, who had been installed at Ségou, unsuccessfully attempted to exert control over the whole Tukulor empire in a series of civil wars. He became head of the Ségou Tukulor empire, whose predominantly Bambara inhabitants led constant revolts against his rule.

The French, who established a fort at Médine in western Mali in 1855, viewed the Ségou Tukulor empire as the principal obstacle to their acquisition of the Niger River valley. Fearful of British designs on the same region, they engaged in a series of diplomatic overtures and military operations to push the boundaries of their control eastward. Between 1880 and 1881 the French succeeded in expanding their control from Médine 200 miles east to Kita, primarily through the diplomatic efforts of Captain Joseph-Simon Gallieni, who signed protectorate treaties with chiefs at Bafoulabé and Kita.

In 1883 Gustave Borgnis-Desbordes launched a series of military campaigns against the Tukulor and the forces of Samory Touré, a Dyula Muslim leader who had founded a state to the south in the 1860s. Desbordes captured Bamako during that year, giving the French a presence on the Niger. Between 1890 and 1893, Colonel Louis Archinard launched a series of successful military operations that led to the final conquest of Ségou in 1893. Samory, who was driven into the Ivory Coast, was captured in 1898, the same year that the small Dyula kingdom of Kenedougou around Sikasso was conquered by French forces under

Colonel H.M. Audeod. Timbuktu was conquered in 1894 by the French officers Gaston Boiteaux, Eugène Bonnier, and Joseph-Jacques Joffre, and the southern Sahara was finally pacified by *méharistes* (camel corps) by 1899.

What is present-day Mali became a part of French West Africa. However, its borders were modified at different times and its name was changed as well. For most of its existence the territory was known as the French Sudan.

Independent Mali. Political parties were first formed in 1946, when a territorial assembly was established. The Sudanese Union–African Democratic Assembly (Union Soudanaise–Rassemblement Démocratique Africain; US-RDA) eventually became the dominant party under its charismatic Marxist leader, Modibo Keita. On Nov. 24, 1958, the territory became known as the Sudanese Republic and was an autonomous state within the French Community. On Jan. 10, 1959, Senegal and the Sudanese Republic joined to form the Mali federation under the presidency of Keita. Hopes that other Francophone states would join the union never materialized, and on Aug. 20, 1960, the federation broke up because of major policy differences between the Senegalese and Sudanese. On Sept. 22, 1960, a congress of the US-RDA proclaimed the independent country of the Republic of Mali.

Keita, the new country's first president, rapidly Africanized the civil service, distanced the country from France, established close diplomatic relations and economic ties with communist-bloc countries, and built a state-run economy. In 1962 Mali issued its own nonconvertible currency, although Keita entered into monetary negotiations with the French in 1967 to prop up a sagging economy. Keita, while claiming to be nonaligned, regularly supported the communist bloc in international affairs. His radical socialist political and economic policies and a cultural revolution launched in 1967 led to widespread popular discontent, which created a favourable environment for a group of army officers to seize power. On Nov. 19, 1968, they launched a coup that overthrew Keita and his government. Led by Lieutenant Moussa Traoré, the officers formed a 14-member Military Committee of National Liberation that ruled Mali from 1969 to 1979, when a civilian government was elected. Disagreements led to the removal of two officers in 1971, and in 1978 four others, who opposed a return to civilian rule, were accused of planning a coup and were arrested; two of them later died in prison.

In 1974, Malians overwhelmingly approved a new constitution. Under it the country returned to civilian rule in 1979, with a military-sponsored political party, the Mali People's Democratic Union (Union Démocratique du Peuple Malien; UDPM), in control of the government and Traoré serving as head of state. When elections were held in 1979 he was elected president, and he was reelected in 1985, while the UDPM occupied all the seats in the National Assembly. During the 1980s Traoré gave civilians access to the government through regular local and national elections, and he also dealt effectively with protests and with a number of coup attempts.   (P.J.I.)

Traoré consistently followed a pragmatic foreign policy, maintaining close relations with both France and the communist bloc. During the 1980s he made concerted efforts to improve relations with other Western countries and promote economic reforms. Mali had two armed conflicts with Burkina Faso over a border area—in 1974–75 and again in 1985. The latter conflict took place in December 1985 and lasted five days; the territory in question was the Agacher Strip, a border region of about 1,200 square miles (3,100 square kilometres). The matter was referred to the International Court of Justice, which divided the territory in 1988 to the satisfaction of both parties.

Serious demonstrations and riots over the increasingly corrupt regime broke out in major urban centres, leading to a military takeover in March 1991 and the imprisonment of Traoré. The new military government, led by Amadou Toumani Touré, promised a quick return to civilian rule, and in elections held in 1992, Dr. Alpha Konaré, a prominent civilian intellectual, won the presidency.

A multiparty government raised hopes of a more democratic future. President Konaré's efforts to rebuild Mali were hampered, however, by a weak economy, drought,

decreasing foreign aid, and the devaluation in 1994 of the CFA franc by the French government. The government also faced a continuing crisis caused by Tuareg rebels, who began returning to their homes in the northern part of the country from Libya and Algeria, where they had migrated in times of drought in the 1970s and '80s. Nevertheless, Konaré was reelected in May 1997 amid charges of electoral fraud and human rights abuses. The political situation subsequently became more stable, and a fragile peace was established with the Tuareg rebels. Surprisingly, Touré, the former military leader who had handed the government over to civilians in 1992, became president of the country in 2002 on a nonpartisan platform.

(P.J.I./Ed.)

For later developments in the history of Mali, see the BRITANNICA BOOK OF THE YEAR.

Mauritania

The Islāmic Republic of Mauritania (al-Jumhūrīyah al-Islāmīyah al-Mūrītānīyah, or République Islamique de Mauritanie), a state in northwestern Africa, forms a geographic link between the North African Maghrib (a region that also includes Morocco, Algeria, and Tunisia) and the Senegal region of western Africa. Culturally it forms a transitional zone between the Arab-Berber region of North Africa and the region to the south of the tropic of Cancer known as the Sudan (a name derived from the Arabic bilād as-sūdān, "land of the blacks"). With an area of 398,000 square miles (1,030,700 square kilometres), Mauritania has the shape of an indented rectangle measuring about 930 miles (1,500 kilometres) from north to south and about 680 miles from east to west. It is bordered to the northwest by Western Sahara (formerly Spanish Sahara), to the northeast by Algeria, to the east and southeast by Mali, and to the southwest by Senegal. Its Atlantic Ocean coastline, to the west, extends for 435 miles from the delta of the Sénégal River northward to the Cap Blanc Peninsula. The capital is Nouakchott.

Mauritania, formerly French-administered, became independent on Nov. 28, 1960. By the terms of the constitution, Islām is the official state religion, but the republic guarantees freedom of conscience and religious liberty to all. Arabic is the national language, and the official languages are Arabic and French.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief, drainage, and soils.* Both land relief and drainage are influenced by the aridity that characterizes the greater part of the country. The impression of immensity given by the landscape is reinforced by its flatness; the coastal plains are lower than 150 feet (45 metres), while the higher plains of the interior vary from 600 to 750 feet. The interior plains form a plateau of which the culminating heights, occurring at different levels, form many tablelands joined to one another by very long, gentle slopes of about 2°. The topography is relieved by vestiges of cliffs (generally cuestas); by sloping plains that terminate at one end of the slope with a steep cliff or faulted scarp, which may reach heights of 900 feet; or by inselbergs (steep-sided residual hills), of which the highest is Mount Ijill at 3,002 feet (915 metres), an enormous block of hematite.

Structurally, Mauritania may be divided into three principal zones. The first of these, located in the north and northwest, consists of underlying Precambrian rock (about 2.7 billion years old), which emerges to form not only the backbone of northern Mauritania's Rigaibāt ridge region but also the Akjoujt rock series that forms a vast peneplain (a land surface worn down by erosion to a nearly flat plain) studded with inselbergs. The second zone is located partly in the extreme north but mostly in the centre and east. In the north it consists of primary sandstone, which covers the Tindouf Syncline (a fold in the rocks in which the strata dip inward from both sides toward the axis); in the centre is the vast synclinal basin of Taoudeni, bounded by the Adrar, Tagant, and 'Açâba plateaus. The basin is scarcely indented to the south by the Hodh Depression, with the Affollé Anticline (a fold in which the rock strata incline downward on both sides from a central axis) lying in its

Plains and plateaus (margin)

centre. The third zone is formed by the Senegalese-Mauritanian sedimentary basin, which includes coastal Mauritania and the lower Sénégal River valley of the southwest.

The Mauritanian landscape in general, as a result of the arid phases it underwent during the Quaternary period (*i.e.*, within the past 1.6 million years), presents three different aspects; these are represented by skeletal soils, regs (desert surfaces consisting of small, rounded, tightly packed pebbles), and dunes.

Skeletal soils are formed where outcrops of the underlying rock have been slightly weathered or where they have been covered with a patina or chalky crust. To these may be added the saline soils of the salt flats, formed from the caking of gypsum or of salt derived from the evaporation of former lakes. The regs form plains often of great extent, carpeted with pebbles and boulders. The dunes cover about half of the total area of the country. They are stretched out, often for several dozen miles, in long ridges known as *'alâb,* which are sometimes 300 feet high; they frequently overlap with one another, forming a network of domes and basins.

It is only to the south of the 10-inch isohyet (an imaginary line connecting points with equal rainfall) that the sands bear a brown type of soil. This soil is characteristic of the steppe (treeless plains) and contains 2 percent humus. It is also only in the extreme southern part of the country that the iron-bearing lateritic soils of the Sudanic zone begin; in the lowest places occur patches of hydromorphic soils—that is to say, soils that have been altered by waterborne materials.

The drainage system is characterized by a lack of pattern. Normal drainage is limited to inland southwestern Mauritania, where tributaries of the Sénégal River, which forms the frontier between Mauritania and Senegal, flow southward and are subject to ephemeral flooding in summer. In the greater part of the country, however, the plateaus are cut into by wadis (dry riverbeds), where the rare floods that occur dissipate their waters into a few permanent drainage basins called *guelt* (singular *guelta*). In the wastes of the north and the east, rainfall is so rare and slight that there is practically no runoff.

Climate. The climate owes its aridity to the northeastern trade winds, which blow constantly in the north and throughout most of the year in the rest of the country; the drying effect produced by these winds is increased by the harmattan, or east wind. With the exception of the few winter rains that occur as a result of climatic disturbances originating in the mid-latitude regions, precipitation essentially results from the rain-bearing southwesterly winds, which progressively extend throughout the southern half of the country at the height of the summer. The duration of the rainy season, as well as the total annual amount of rainfall, diminishes progressively from south to north. Thus, Sélibaby in the extreme south receives about 25 inches (635 millimetres) between June and October; Kiffa, farther north, receives 14 inches between mid-June and mid-October; Tidjikdja receives seven inches between July and September; Atar receives seven inches between mid-July and September; and Nouadhibou receives between one and two inches, usually between September and November. Because of opposition between the wet southwesterlies and the harmattan, rains often take the form of stormy showers or squalls.

The strength of the sun and the lack of haze in these latitudes result in high temperatures. In the summer months afternoon temperatures exceed 100° F (38° C) at most stations, and daily highs of 115° F (46° C) are not uncommon in the interior. The average temperature in the coldest month at most stations is in the region of 68° F (20° C), while the average temperature during the hottest month rises to about 75° F (24° C) at Nouakchott in September, to about 79° F (26° C) at Kiffa in May, to 81° F (27° C) at Atar in July, and to 84° F (29° C) at Néma in May.

Plant and animal life. Vegetation zones depend upon the degree of aridity, which increases from south to north. The Sudanic savanna, studded with baobab trees and palmyra palm trees, gradually gives way in the extreme south to a discontinuous belt of vegetation known as the Sahel (an Arabic word meaning riverbank, or shore, which

Aridity (margin)

is also used to designate the southern Sahara borderlands). In the Sahel, trees are rare and the vegetation consists principally of acacias, euphorbia bushes (plants of the spurge family that have a milky juice and flowers with no petals or sepals), big tufts of morkba (*Panicum turgidum,* a type of millet), or fields of *cram-cram,* or Indian sand-bur (*Cenchrus biflorus,* a prickly grass). Between the six-inch and four-inch isohyets the steppe rapidly disappears, giving way to desert. Vegetation is restricted to such places as the dry beds of wadis, beneath which water continues to flow, or to oases.

In the savanna, big antelope are hunted by lions, and, in the hilly Afollé region of southern Mauritania, herds of elephants are found. The steppe is frequented by gazelles, ostriches, warthogs, panthers, hyenas, and lynx; crocodiles are found in the *guelt.* Only addax antelope venture out into the waterless desert. Animal populations have been much reduced by hunting, obliging the authorities to introduce measures for conservation.

The Sahara and Sahel regions

Settlement patterns. The Sahara region to the north, where habitation is generally limited to oases, stands in contrast to the Sahelian steppelands to the south, where regular rainfall permits extensive stock raising and some agriculture. While transition occurs between one zone and another, a convenient line of demarcation is represented by the four-inch isohyet.

The heartland of Mauritania consists of the vast Adrar and Tagant plateaus, known as the Trab el-Hajra (Arabic: "Country of Stone"). There, at the foot of cliffs, are found several oases, among which some—such as Chinguetti, Ouadane, Tîchît, Tidjikdja, and Atar—were the sites of well-known cities in the Middle Ages. To the north and the west extend the vast desert peneplains. The exploitation of the Zouîrât mines and the development of Nouad-hibou have transformed this once-abandoned region into the focus of Mauritania's economic life.

Coastal southwestern Mauritania (under colonial rule, the Trarza *cercle*) is covered with regularly aligned dunes and is important for stock raising; Arab-Berber (Moorish) culture is represented by important marabout families.

Inland, southwestern Mauritania is inhabited by Moors and Fulani (Peul), who engage in both livestock raising and agriculture. In the extreme south, large villages are surrounded by fields of millet, constituting the first sign of the Sudanese landscape.

In the southeast the vast Hodh Basin, with its dunes, sandstone plateaus, and immense regs, is a major live-stock-raising region, the economy of which has many links with neighbouring Mali.

Mauritania is a country suited for nomadic life. Livestock supplies the nomads with milk and meat, while transport is provided by riding camels and pack camels and, in the south, by pack oxen and donkeys as well. The women dye sheep's wool, with which they then braid long brown bands that are sewn together to make tents; they also tan goats' skins to make *guerba*s (waterskins). Movement is governed by the search for water and pasturage. In the Sahara nomadic movements are irregular because of the extreme variability of rains; in the Sahel, however, regular seasonal movement occurs—to the south in the dry season and back to the north in the wet season. Sizes of nomadic encampments also vary from south to north. In the coastal southwest, agglomerations of up to 300 tents may be found, whereas in northern Mauritania only groups of a few tents are to be seen.

The decline of nomadism

For a variety of reasons—including changes in agri-cultural patterns as well as in political and commercial relations—the traditional nomadic way of life has been declining. Dams to conserve floodwaters have been built in the wadis, and palm tree culture has been considerably extended. The cumulative result of these developments has been that the nomads now tend to remain longer in the south near their millet fields and palm groves—becoming, in effect, seminomads.

Since the 1960s a movement toward settlement has been evident, largely because of growing dissatisfaction with the harsh conditions of nomadic life; this movement, how-ever, has been restricted by the constant lack of water. Only in the extreme south—on the banks of the Sénégal

River (in Mauritania the region called the Chemama)—is a normal, settled agricultural life possible. A series of droughts halted cultivation in the Sahel in the 1970s, and livestock raising was seriously constrained, affecting the livelihood of nomads and sedentary peoples alike.

The exploitation of the iron ore reserves of Mount Ijill, as well as the achievement of independence, have trans-formed the urban geography of Mauritania. The ancient cities that lived by caravan traffic—*e.g.,* Tîchît, Chinguetti, Ouadane, and Oualâta—and traded with Casablanca and, above all, with Dakar have grown idle beneath their palm trees. Only Tidjikdja and Atar have maintained a certain activity. Kaédi, on the Sénégal River, has expanded and is still growing. Three new towns have been built: Nouak-chott, the capital; Fdérik (formerly Fort-Gouraud); and Nouadhibou (formerly Port-Étienne).

Nouakchott was founded in 1958. Formerly, Mauritania shared a capital, Saint-Louis, in Senegal, with the other members of the French West African Federation. Nouak-chott is located near the sea and provides access to the Sahara and Sahel regions. In addition to being the seat of government and administration, Nouakchott is a growing commercial centre and has a printing works, a hospital, and numerous schools. Its water supply is pro-vided by a plant that desalinizes seawater.

Fdérik is an administrative centre situated about 15 miles from the mining town of Zouîrât. The port of Nouad-hibou, which was long stagnant, owes its more recent expansion both to expanding iron ore exports and to the establishment of a fishing complex there. A few miles to the south lies Cansado, a residential suburb.

The Moors

The people. *Ethnic and linguistic groups.* The Moors constitute more than two-thirds of the population; about half of them are white, or *bidän,* Moors of Arab and Berber descent, and about half are black Moors, of Su-danic origin. Moorish society historically was divided into a hierarchy of castes. At the head of the socioeconomic structure were the noble castes, composed of *'arab*s, or warriors, and *Murābit* (marabouts), or priests and scholars of the Qur'ān. The warriors were usually Arab, and the marabouts were usually Berber. The mass of the *bidän* population were vassals who received protection from the warriors or marabouts in return for tribute. There were two artisan classes—the blacksmiths and the griots (who were at once musicians and genealogists). Servant classes were formed of black Moors and were subdivided into *'abid,* or slaves, and *hartani,* or freedmen. Among the ethnic and racial groups, blacks became the better educated and held most technical, professional, and diplomatic posts at the time of independence. Members of this "servant" caste, which developed as the bureaucratic class, became increasingly aware of their rights as citizens. Slavery was abolished by the French before independence and was officially abolished again on July 5, 1980, but subsequent reports claimed that the practice had continued.

The Moors speak Ḥassānīyah, a dialect that draws most of its grammar from Arabic and uses a vocabulary of both Arabic and Berber words. Most of the members of the aristocratic castes also know literary Arabic.

The remaining population, generally referred to as *kewrin,* consists of Tukulor (Toucouleur), who live in the Sénégal River valley; Fulani, who are dispersed throughout the south; Soninke (Sarakole), who inhabit the extreme south; and Wolof (Oulof), who live in the vicinity of Rosso in coastal southwestern Mauritania. The Tukulor and the Fu-lani speak Fulfulde (Poular), and the other ethnic groups have retained their respective languages.

Of Mauritania's total population an estimated one-fourth are nomads, and about one-third live in and around ur-ban centres. Because of the country's large desert area, the average density is the lowest in western Africa. Three-fourths of Mauritanians live in the Sénégal River valley. Life expectancies stand at 44 and 47 years respectively for men and women.

Most of the non-Africans in Mauritania are French na-tionals engaged in technical assistance, commerce, and mining; Spaniards represent the second largest foreign community.

Religious groups. About 99 percent of all Mauritanians

are Muslim. Most Moors belong to the Qādirīyah order. The Tukulor and some of the Tagant tribes belong to the Tijānīyah order. Many tariqas (mystical sects) flow from these orders.

The economy. In the Sahel region of Mauritania a traditional subsistence economy is maintained, composed of livestock raising, agriculture, crafts, and petty trading. In the Sahara region, however, a modern economy is developing, based on the exploitation of iron-ore and copper resources and of the ichthyologically-rich continental shelf; the modern economy receives much needed capital investment and technical assistance from abroad. More than three-quarters of the Mauritanian population still lives by traditional activities, among which livestock raising is the most important. In numbers, goats and sheep are the most important livestock, followed by cattle, camels, donkeys, and horses. Cattle are raised primarily in the southern region, whereas goats and sheep are dispersed as far north as the limits of the Sahara. Camels are raised mostly in the north and the centre, especially in the Adrar region. The growth of the Mauritanian economy slowed in the 1980s after a lengthy period of rapid expansion in the 1960s and '70s. Agriculture and fishing account for almost one-third of the gross national product, with the industrial sector, including mining, contributing about one-quarter, public administration about 15 percent, and the remaining sectors about 30 percent.

The state imposes indirect taxes on imports, a turnover tax on exports and mining, a service tax, and taxes on cattle, vehicles, wages and salaries, and profits from industrial and commercial concerns.

Mauritania's budget, usually in deficit, was nominally balanced in the late 1980s. In the mid-1980s, principal and interest on a relatively large foreign indebtedness was rescheduled, but indebtedness remains a significant problem. Foreign aid, both bilateral (from France, Japan, China, the United States, and the Arab states) and by multilateral agencies (such as the African Development Bank, International Monetary Fund, International Bank for Reconstruction and Development, and the European Economic Community), is primarily targeted to assist in project development but is also used for budgetary and food support.

Agriculture and fishing. Agriculture is necessarily dependent upon rainfall. Where the rainfall exceeds 17 inches a year, millet (fonio) and dates are the principal crops, supplemented by sorghum, beans, yams, corn (maize), and cotton. Seasonal agriculture is practiced on the easily flooded riverbanks and in the wadis of the Sahelian zone, upstream from the dams. There, too, millet, sorghum, beans, rice, and watermelons are grown. Irrigated agriculture is practiced in areas supplied by water-control projects and at oases, where well water is available; corn, barley, and some millet and vegetables are grown. The output of gum arabic is less than it was in former years. Agricultural production in Mauritania has continued to decline because of drought. Crop production fell by approximately two-thirds in the period from 1970 to 1980. From the late 1970s Mauritania was unable to produce more than half of its total food requirements.

In agriculture the aim of successive Mauritanian governments has been to increase the amount of irrigated land in the Sénégal River valley and, above all, to increase the production of rice, of which Mauritania is still obliged to import large quantities, to plant fresh palm trees to replace those destroyed by the cochineal insect, to drill fresh wells, to improve the quality of dates, and to encourage the cultivation of vegetables.

Rich fishing grounds lie off Mauritania's Lévrier Bay. Mauritania stopped issuing fishing licenses in 1979, however, and in 1980 formed joint companies with Portugal, Iraq, South Korea, Romania, and the Soviet Union. In 1987, fisheries agreements were signed with the European Communities. At Nouadhibou fish are canned, frozen, or processed as fish flour. Several tons each year are dried and exported to other African countries.

Mining. A rail link connects the mining town of Zouîrât with the port of Nouadhibou, the only deepwater roadstead on the Saharan coastline, accommodating ships of

(margin note: Livestock raising)

(margin note: Iron ore and copper)

Iron ore mine at Zouîrât, Mauritania, with the Adrar plateau in the background.
Shostal Associates/Superstock

up to 150,000 tons. Iron exploitation was organized and begun in 1963 by Miferma (of which 56 percent of the financing was by French groups and the remainder by British, West German, and Italian groups and by the Mauritanian government). The company was nationalized in 1974 and was renamed Cominor (Complexe Minier du Nord). The iron ore deposits of Mount Ijill have nearly been exhausted, and exploitation of reserves at Guelbs began in 1984. Iron exports fell from a peak of 12 million tons in 1974 to an annual average of nine million tons in the 1980s.

The copper deposits of Akjoujt are extensive, with a copper content of more than 2 percent. Exploitation was begun in 1969 by Somima (Société Minière de Mauritanie), of which 54 percent of the shares were held by British and U.S. interests, 25 percent by the Mauritanian government, and the remainder by French interests. Somima was nationalized in 1975, but operations were suspended in 1978. Reactivation of the mine remains a constant preoccupation, as does the extraction of gold from the copper ore. Processed copper had been exported along a highway to the wharf at Nouakchott. There are substantial gypsum deposits near Nouakchott; most of the annual production is exported to Senegal. Other mineral resources are minor, and salt output has declined. Reserves of ilmenite (the principal ore of titanium) have been located, and phosphate deposits have been identified near Bofal in the south. Oil prospecting has so far yielded no results.

Finance and trade. The national Banque Centrale de Mauritanie was established in 1973. In addition there are five commercial banks. There are no securities exchanges in Mauritania, and the government controls all insurance business.

Foreign trade is difficult to estimate because, while imports and exports of the modern sector are well known, there are no statistics for the traditional sector. Mauritania is nevertheless known to import from or by way of Senegal quantities of millet, tea, rice, sugar, cotton goods, and hardware, while it exports to Mali and to Senegal cattle, sheep, and goats. Iron ore together with fish and fish products constitute the major exports.

Transportation. Transport by pack animals—camels in the north, oxen and donkeys in the south—has retained considerable importance in a society in which a subsistence and barter economy prevails, although transport between cities and regions is increasingly by truck. Considerable hazards, however, confront road builders; among these are moving sand dunes, flash floods in the south,

and steep cliffs. Only the main road running from Rosso via Nouakchott, Akjoujt, Atar, Fdérik, and Bir Mogreïn to Tindouf, Algeria, is passable throughout the year. The road between Rosso and Nouakchott is surfaced, as is the section between Nouakchott and Akjoujt. The Trans-Mauritania highway, linking Nouakchott, Kaédi, Kiffa, 'Ayoûn el-'Atroûs, and Néma, was completed in 1982. The railroad from Zouîrât to Nouadhibou is used only for transporting iron ore. There are international airports at Nouakchott and Nouadhibou, and other cities are linked by regular air services.

The irregularity of the flow of the Sénégal River limits its use as a waterway; Kaédi can be reached only by ships drawing about seven feet at the high-water season, normally from August to October. The port facilities at Nouakchott can accommodate 320,000 tons of shipping a year. Nouadhibou, in addition to being an iron ore and fishing port, is also a commercial port.

Administration and social conditions. *Government.* The Mauritanian state had a presidential regime from 1960 until 1978, when a coup d'état installed a military government. A civilian government established in December 1980 was replaced the following April by a largely military administration. A new constitution in 1991 established a multiparty system and a bicameral legislative structure.

The primary task of Mauritania's successive governments has been to transform a community of diverse tribes, hierarchical in social structure and very strongly differentiated, into a nation. Many of the local barriers to cooperation have been overcome, and traditional regional boundaries have been redrawn. There are 12 administrative regions, each directed by a governor, with the capital forming a separate district.

Islamic law and jurisprudence Islāmic law and jurisprudence have been in force since February 1980. *Qādīs* (judges of the Sharī'ah, or Islāmic law) in rural and town communities hear cases relating to marriage, divorce, and other personal status issues. Nouakchott is divided into six regional sections where magistrates and judges hear cases in lower courts; there are also labour and military courts, the Court of State Security, and a Supreme Court, which deals with administrative as well as judicial matters.

Education. Less than two-fifths of Mauritania's adult population is literate. Schooling is compulsory to age 14, but, in fact, only a small minority of children benefit from it. In addition to primary schools in the urban centres, there are secondary schools, a university with faculties of letters and human sciences and of law and economics, and a research institute for mining and industry in Nouakchott. The capital is also the site of a national library. There are traditional local libraries in some urban centres.

Health and welfare. Modern health facilities are scarce in Mauritania, with only one major hospital in Nouakchott and 25 other regional health centres, of which 15 are maternity clinics. Free medical services are available to the poor. Traditional medicine flourishes. Among other health problems found in tropical areas, tuberculosis and intestinal and eye maladies are widespread. Disability payments for industrial accidents and occupational diseases, family allowances, and old-age pensions are administered by the National Social Insurance Fund.

Cultural life. Moorish society is proud of its Arab and Muslim heritage. Theology, poetry, and music flourish. Goldsmithing is a fine art. Kewri societies have a rich and varied folklore.

Mail, telephone, and telegraph services are combined in the main post offices. Fewer than 15,000 telephones are in use, and administrative contact is primarily through radiotelephone. International telephonic communications are run through Paris. The media are owned or controlled by the government. A national radio network broadcasts in the prevailing languages and in French. There are also two Earth satellite stations with telecasts in French and Arabic. A daily, *Ach-chaab;* a biweekly, *Journal Officiel;* and a bimonthly, *Le Peuple,* are published in the two official languages. Movie theatres are found in the main urban centres, and *cercles* (social, sporting clubs) provide recreational opportunities in Nouakchott, Nouadhibou, and Rosso. (C.H.T./A.G.G.)

For statistical data on the land and people of Mauritania, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

Numerous remains have been discovered in northern Mauritania dating from the Acheulian (Lower Paleolithic) and Neolithic periods. In historical times Mauritania was settled by both sub-Saharan peoples and by the Sanhadja Berbers. The region was the cradle of the Berber Almoravid movement, which spread an austere form of Islām to all the neighbouring peoples in the 11th century AD. A caravan route linked Mauritania with Morocco at that time, and Arab tribes following this route in the 15th century soon outnumbered the Berbers, and a mixed Arab-Berber (Moorish) culture was born. These nomadic tribes formed several powerful confederations: the Trarza and Brakna, which dominated the Sénégal River valley; the Kunta in the east; and the Rigaibāt (Regeibat) in the north.

The Berber Almoravids

European intervention. In 1442, Portuguese mariners rounded Cape Blanc and in 1448 founded the fort of Arguin, whence traders derived gold, gum arabic, and slaves. Later French and English shipping frequented Portendick, and the French settled at Saint-Louis at the mouth of the Sénégal River. In 1858 Colonel Louis Faidherbe waged a military campaign that ended Moorish domination in lower Sénégal. After 1898 an Orientalist, Xavier Coppolani, succeeded in rallying all the Moors of the south to French allegiance. His work was completed by Colonel Henri Gouraud, who occupied Tagant in 1907 and Adrar in 1909. The Rigaibāt were not subjugated until 1955.

Mauritania was constituted a territory of French West Africa in 1920 and later became a French colony; it was at first governed from Saint-Louis in Senegal. In 1946 Mauritania became a French overseas territory and in 1957 elected a government under Moktar Ould Daddah, who established the new capital at Nouakchott. In 1958 Mauritania voted to become a member state of the French Community. (H.J.D./Ed.)

Independence. Mauritania's small political elite was divided over whether the country should be oriented more toward Senegal and French-speaking sub-Saharan Africa or toward Arab-Muslim Morocco—whose leaders sought to absorb Mauritania. The winning faction, under Sidi el-Moktar N'Diaye and his political successor, Ould Daddah, chose independence—which the country declared on Nov. 28, 1960—with close ties to France. The new state became a member of the United Nations in 1961. Mauritania opted for full participation in the Organization of African Unity and joined the Arab League in 1973.

Relations with Morocco

As Mauritania's first postindependence president, Ould Daddah appeared securely established in spite of occasional strikes by miners and demonstrations by students, for his policies seemed attuned to a population that was largely tribal and engaged in agriculture or pastoralism. King Hassan II of Morocco had reversed his policy and recognized Mauritanian independence in 1969 as part of his plan to gain control of Spanish Sahara (later Western Sahara), and the two sides divided the country in 1976. The difficulties of suppressing guerrillas of the Polisario Front in Mauritania's portion of the Western Sahara contributed to Ould Daddah's downfall, and he was deposed in a military coup led by Colonel Mustapha Ould Salek in July 1978.

Ould Salek resigned his position in June 1979, and under his successor, Lieutenant Colonel Mohamed Mahmoud Ould Louly, Mauritanian signed a treaty with the Polisario Front in August in an effort to disentangle itself from Western Sahara. This worsened relations with Morocco. Ould Louly was in turn replaced in January 1980 by the prime minister, Lieutenant Colonel Mohamed Khouna Ould Haidalla. In December 1984 Colonel Maaouya Ould Sidi Ahmed Taya took over the presidency and the office of prime minister from Haidalla in a bloodless coup, and Mauritania renewed diplomatic ties with Morocco in 1985, seeking again to resolve the dispute in Western Sahara. Taya was victorious in the country's first multiparty presidential elections in 1992 and was reelected in 1997. (Ed.)

For later developments in the history of Mauritania, see the BRITANNICA BOOK OF THE YEAR.

Niger

The Republic of Niger (République du Niger), a land-locked western African country, takes its name from the Niger River, which flows through the southwestern part of its territory. The name Niger derives in turn from the phrase *gher n-gheren,* meaning "river among rivers," in the Tamashek language. The republic has an area of 458,075 square miles (1,186,408 square kilometres). It is bounded on the northwest by Algeria, on the northeast by Libya, on the east by Chad, on the south by Nigeria and Benin, and on the west by Burkina Faso and Mali. The capital is Niamey.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Niger extends for about 750 miles (1,200 kilometres) from north to south and about 930 miles from east to west. It tends to monotony in its features, is intersected by numerous depressions, and is dominated by arid highlands in the north. Rainfall increases as one proceeds southward so that the country divides naturally into three distinct zones—a desert zone in the north; an intermediate zone, where nomadic pastoralists raise cattle, in the centre; and a cultivated zone in the south. It is in this southern zone that the greater part of the population, both nomadic and settled, is concentrated.

Three geographic zones

The highlands of the north are cut by valleys (*kori*) of the Aïr Massif, which is an extension of the Ahaggar (Hoggar) Mountains of Algeria, and consists of a range running north to south in the centre of Niger, with individual mountain masses forming separate "islands": from north to south these are Tazerzaït, where Mount Gréboun reaches an altitude of 6,379 feet (1,944 metres); Tamgak; Takolokouzet; Angornakouer; Bagzane; and Tarouadji. To the northeast is a series of high plateaus, which form a bridge between the Ahaggar Mountains of Algeria and the Tibesti Mountains of Chad. From west to east these are the plateaus of Djado, Mangueni, and Tchigaï.

The sandy regions of the Nigerian Sahara extend to either side of the Aïr. To the west the Talak region includes the Tamesna area in the north (where fossil valleys are filled with moving sand dunes) and the Azaoua area in the south. East of the Aïr is the Ténéré region, covered partly by an expanse of sand called an erg, partly by a stony plain called a reg.

The plateaus of the south, which form a belt about 900 miles long, may be divided into three regions. To the west is the Djerma Ganda region. Its large valleys are filled with sand, while *dallol* (fossilized valleys of rivers that formed tributaries of the Niger in ancient times) descend from the

Tuareg with their herds at an oasis in the Aïr Massif, northern Niger.

Aïr and the Iforas Massif of neighbouring Mali. The central region consists of the rocky Adar Doutchi and Majia areas; it is the region of the *gulbi* (dried-up valleys of former tributaries of the Sokoto River) and the Tegama—a tableland of sandstone, ending, toward the Aïr, at the Tiguidit scarp. To the east the underlying rock reappears in the Damagarim, Mounio, and Koutous regions, to the north of which is the region of Damergou, consisting of clays. In the Manga region, in the east, traces of ancient watercourses appear on the sandy plain.

Drainage and soils. It is convenient to make a distinction between the ancient hydrographic system, which allowed agriculturalists, fishermen, and pastoralists to live in the Aïr region about 5,000 or 6,000 years ago, and the present simple system, which forms the basis of the marked difference between the northern and southern parts of the country. The present system includes to the west the Niger River basin and to the east the basin of Lake Chad; between the two occur vestiges of the older system, such as the *dallol* and the *gulbi.*

To the west the Niger River crosses about 350 miles of Niger's territory. Because of the change in river flow, which occurs because of the dispersal of its waters in its interior delta region in Mali, it is only in January and February that it flows past Niamey in flood. At other times the river is fed by certain temporary watercourses that flow in from the right bank. These are the Gorouol, the Dargol, the Sirba, the Goroubi, the Djamangou, the Tapoa, and the Mékrou; the last two flow through the "W" National Park (so called because the Niger flows through the area in the form of a W). On the left bank, proceeding eastward, appear the *dallol,* the vestiges of the older watercourses. Generally running from north to south, they constitute zones of dampness, although a few still contain waters that flow toward the Niger. The best known are the Bosso, the Foga, and the Maouri wadis. Other vestiges consist of the *kori,* which run down from the Aïr and from former tributaries that had their sources in the Iforas Massif, and which flowed to a confluence at what is now the Ti-m-merhsoï Wadi. No waters flow through the *kori* now, but water is still to be found beneath their sands. Other remnants of the old system are formed by the *gulbi,* through which water still flows annually, occasionally causing damage.

Ancient watercourses

To the east is situated the basin of Lake Chad, a large, shallow lake, which at its highest contemporary level has an area of approximately 9,650 square miles; of this, Niger possesses about 1,100 square miles. Its extent is considerably reduced during the dry season. The Komadougou Yobé River, which flows into Lake Chad from the west, forms part of the frontier between Niger and Nigeria. Its water level, which begins to rise in August, from January to May consists only of some stagnant pools.

In addition to the drainage system described, it may be noted that rainwater collects in several basins, so that some permanent lakes or pools also exist; these are found at Keïta and Adouna in the Adar Doutchi region, at Madaroumfa in the Maradi *gulbi,* and at Guidimouni to the east of Zinder. The water table in some areas can also be tapped to produce artesian wells.

The soils fall into three natural regions. In the Saharan region in the north the soil is infertile, except in a few oases where water is found. In the region known as the Sahel, which forms a transitional zone between the Sahara and the region to the south, the soils are thin and white, being covered with salty deposits resulting from intense evaporation that forms an infertile surface crust. The third region (in the south) is cultivated. In this area the soils are associated with extensive dunes or uplands or with basins or depressions. Some of the soils in the latter, such as those in the Niger basin and in the *gulbi,* are rich. Black soils occur in the Kolo basin. Throughout the region, however, and above all on the plateaus, less fertile lateritic (leached iron-bearing) soils occur.

Climate. Niger extends southward from the tropic of Cancer, and the northern two-thirds of its territory lies in dry tropical desert. In the southern part of the country the climate is of the type known as Sahelian, which is characterized by a single, short rainy season. In January

and February the continental equivalent of the northeast trade winds, the harmattan, blows southwestward from the Sahara toward the equator. Typically dust-laden, dry, and desiccating, the harmattan hinders normal living conditions on the southern fringe of the desert. From April to May the southern trade winds blowing from the Atlantic reach the equator and are diverted toward the Sahara where they meet with the harmattan—an encounter that results in violent line squalls and that signals the beginning of the rainy season. The rains last from one to four months, according to the latitude; August is the rainy month everywhere except in the far north, where the rainfall is unpredictable.

Niger lies in one of the hottest regions of the world. Temperatures rise from February to May and drop during the "winter" rainy season, rising again somewhat before falling to their annual minimum averages in December or January. During May (the hottest month), afternoon temperatures are high everywhere, ranging from a low of about 108° F (42° C) at Nguigmi on Lake Chad to 113° F (45° C) at Bilma and Agadez, both in the northern desert. In January, afternoon temperatures average more than 90° F (mid-30s C) at most stations but at night may drop to freezing level in the desert. The daily range is greater in the desert north than in the south and is also more extreme during the dry season.

Rainfall varies according to location as well as season. The 10-inch isohyet (line on a map connecting points having equal rainfall) follows a line from near Tahoua to Gouré, in effect marking the northern limit of nomadic pastoral life, for the rainfall permits a sparse vegetation to grow. To the extreme south the 30-inch isohyet marks the southern limit of this zone, after which the southern agricultural zone begins. In the course of the same rainy season a most irregular spatial pattern of rainfall may occur, while from one year to another the total amount of rainfall may also vary; in addition, the rainy season itself may arrive early or late, thus jeopardizing crops.

Plant and animal life. The vegetation of the desert zone clusters around the oases; it includes the date palm and cultivated corn (maize). Animal life, which must be able to endure hunger and thirst, includes the dromedary.

In the Sahel zone, where the doum palm and the *cramcram* (*Cenchrus biflorus,* a prickly grass) appear, the vegetation has a short life cycle and is principally used for grazing. Animal life includes the ostrich and the gazelle.

In the cultivated zone the vegetation includes acacia trees, doum palms, and palmyra palms, as well as baobabs. Wildlife, which has partially disappeared, includes antelope, elephants, and warthogs; giraffes are found in the Zarmaganda and Damergou regions, and hippopotamuses and crocodiles on the banks of the Niger. The extreme southwest is a savanna region where baobabs, kapok trees, and tamarind trees occur. Animal life is preserved in the "W" National Park, where antelope, lions, buffalo, hippopotamuses, and elephants may be seen.

Settlement patterns. The southern part of Niger's territory is situated in the vast region of Africa known as the Sudan, in which, in former times, large political states arose, such as Ghana, Mali, and Songhai, as well as the Hausa states, the empire of Sokoto, and Bornu. The northern part of Niger remains the domain of the Tuareg. The country comprises a multitude of traditional regions, the names of which remain despite the establishment of contemporary administrative divisions. All these regions have a fluctuating political, economic, and geographic significance: the Hausa regions, for example, have been cut in two and divided between Niger and Nigeria. Most regions, moreover, have been and remain zones where contact takes place between different peoples—between the Hausa and the Tuareg in the Adar Doutchi region, for example; between the Tuareg and the Kanuri in the Damergou region; and between Hausa and Zerma in the Aréoua area.

About one-fifth of the population live in towns. The rural population comprises nomads and sedentary peoples. There are some 10,000 villages, of which approximately half have only a few hundred inhabitants; there are practically no villages in the desert zone. Fulani (Peul) herds-

men, who breed horned cattle and oxen, and the Tuareg, who raise goats, sheep, and dromedaries, tend to travel over the northern region during the winter. They meet together to permit the cattle to lick the salty soil of the In Gall region during August and September but move southward during the dry season. Both Fulani and Tuareg live in tribal groups, in temporary or portable shelters, and gain their subsistence from their livestock. The Fulani subsist above all on milk in various forms; the Tuareg live on meat and dates.

Sedentary peoples, such as the Hausa, the Songhai-Zerma, and the Kanuri, who inhabit the Niger and Chad basins, live largely by agriculture. They raise millet, rice, corn, peanuts (groundnuts), and cotton. They also work as blacksmiths and shoemakers, while on the banks of Lake Chad and the Niger the Buduma and Sorko peoples are fishermen. Sedentary peoples live in dwellings that vary from those made of straw to those made of banco (hardened mud), although the Wogo people live in tents of delicate matting.

There is a tendency among the nomads to settle down, and the already sedentary peoples are expanding the lands under cultivation toward the north. Rural life, above all in its sedentary form, tends to slow its pace during the long dry season; it is at this time of year that migration to the towns or other countries occurs.

It was approximately in the 15th century that a few towns, such as Agadez or Zinder, were first established as halting places, or depots, on the trans-Saharan caravan routes. As commercial routes gradually developed on the coasts, however, these northern towns lost their former economic importance, while other centres, such as Birni Nkonni, and Tessaoua, declined in the course of the 19th century as a result of the colonial era.

There are four principal towns in Niger. Niamey, the political capital, has experienced rapid growth. It has a cosmopolitan character and a transient population. Its characteristic life varies between the European and African rural styles, including various intermediate steps, of which the life-style of the *évolués* (educated Africans) is the most distinctive. Zinder, for which the African name is Damagaram, is an older town than Niamey; a Hausa town, it was the capital of Niger until 1926 and has a number of skilled craftsmen, especially leatherworkers and dyers. The town has experienced some industrial growth and has close links with Nigeria. Maradi has developed rapidly. The town is situated in the heart of the peanut-growing region near the Nigerian frontier. Many European companies have established branches there; the town is particularly renowned for its red goats, the skins of which are exported to Europe and the Americas. Tahoua has grown up on the edge of the desert. There it forms a large livestock market, where nomad pastoralists and sedentary farmers meet. All of the towns remain little more than modest administrative and commercial centres, but because of the discovery of uranium ore Agadez has experienced a spectacular growth.

The people. *Linguistic groups.* The largest linguistic group is formed by the Hausa, whose language, also spoken in Nigeria, is one of the most important in western Africa. A large percentage of the inhabitants of Niger understand Hausa, which possesses an abundant literature that has been printed in Latin characters in Nigeria. Songhai is the second most important language; it is also spoken in Mali, in northern Burkina Faso, and in northern Benin. In Niger itself it is divided into various dialects, such as Songhai proper, Zerma, and Dendi. The language of the Fulani is Fulfulde; in Niger it has two dialects, eastern and western, the demarcation line between them running through the Boboye district. Tamashek is the language of the Tuareg, who often call themselves the Kel Tamagheq, or Tamashek speakers. The language is also spoken in Algeria and Mali and possesses its own writing, called *tifinagh,* which is in widespread use. Kanuri is spoken not only in Niger but also in Cameroon and Nigeria; the tongue is called Beriberi by the Hausa. While these five languages are the principal ones spoken in Niger, there is also an important Teda linguistic group in the Tibesti region. In addition, many of the peoples of Niger speak Arabic, and a still larger number read and write in

that language; Agadez possesses one of the oldest Arabic schools in Africa. The use of the Arabic alphabet resulted in Fulfulde and Hausa becoming written languages; the script is called *ajami;* a search for more old manuscripts in *ajami* is being conducted.

By using Hausa and Songhai, one may make oneself understood from one end of the country to the other. French, however, remains the official language, as well as the language of instruction, although it remains understood only by a small minority. English is taught as the principal foreign language in secondary schools.

Ethnic groups. Ethnic groups correspond to the five linguistic groups already mentioned. The Hausa are the largest group, constituting more than half of the present population, though the majority of the Hausa people live in Nigeria. The Hausa occupy the centre of southern Niger as far as Dogondoutchi. The Songhai-Zerma are found in the southwest; the Songhai proper live along the Niger, where they are assimilating the Kurtey and Wogo peoples. The majority of the Songhai people as a whole, however, live in Mali. The Zerma (Djerma) live on the left bank of the Niger, remaining in close contact with the Mauri and Arewa peoples. The Fulani, who are dispersed throughout the country, are mostly nomadic; they are also found dispersed throughout western Africa. The Tuareg, also nomadic, are divided into three subgroups—the Iullemmiden of the Azaouak region in the west, the Asben (Kel Aïr) in the Aïr region, and the Itesen (Kel Geres) to the south and east of Aïr. The Tuareg people are also found in Algeria and in Mali. The Kanuri, who live to the east of Zinder, are divided into a number of subgroups—the Manga, the Dogara (Dagara), the Mober, the Buduma, and the Kanembu; they are also found living in Chad, Cameroon, and Nigeria. Apart from the nomadic Teda of the Tibesti region, who constitute an important minority, the remainder of the population consists of Arabs, black Africans from other countries, and Europeans, of whom the greater part are French.

Religious groups. More than 95 percent of the population adhere to the Sunnite branch of Islām. Although the Annaawaa group of Hausa have always refused to accept Islām, as have a group of Fulani, the Wodaabe—who distinguish themselves from other Fulani for this reason—Islām remains the religion of the majority of both Hausa and Fulani. Christianity (Roman Catholicism and Protestantism) remains a religion of the towns, particularly of Niamey. There are several Christian missions in the Songhai and Arewa areas. Christianity is primarily a European religion, although it is also practiced by some black Africans from other countries. The traditional animist religions of the black Africans continue to manifest themselves in strength.

The economy. The economic system is based upon planning but accords an important role to private enterprise. The three main policy objectives are the maintenance of national unity, the elevation of the living standards of the population, and the attainment of economic independence. The private sector of the economy consists partly of a multitude of small enterprises and partly of enterprises belonging to large French or international companies. The government, through the agency of the Development Bank of the Republic of Niger, which is funded partly by aid from abroad, has promoted the establishment of many companies, including real estate, road transport, air transport, and agricultural processing enterprises.

Niger is encouraging economic links between African countries. Apart from its membership in the Organization of African Unity, Niger is a member—together with Côte d'Ivoire, Benin, Burkina Faso, and Togo—of the Conseil de l'Entente, a regional cooperative group, as well as of the Organisation Commune Africaine et Mauricienne, another group of French-speaking African states.

Resources. Salt is traditionally exploited in the Kaouar and Aïr regions, as well as in the *dallol,* and in the Manga district. Natron (hydrated sodium carbonate) is extracted locally. Cassiterite (an ore of tin) is mined at open workings in Aïr. Small quantities of gold are obtained by panning in the Sirba River. Limestone and an important deposit of gypsum have been located at Malbaza and in the

Ader Doutchi and Majia region. Niger's known reserves of uranium rank among the most important in the world. Apart from tungsten in the Aïr region, traces of copper, lignite (a brownish black coal), molybdenum, zinc, phosphates, and titanium have been found and are the subject of further prospection. A reserve of iron ore, with an iron content of about 50 percent, has been located in the Say region; and petroleum deposits have been discovered in the Lake Chad area.

The exploitation of plant resources has long been practiced but on a small scale. The doum palm and the palmyra palm provide wood for construction, while the palms of the Manga oasis produce dates. Small amounts of kapok (a silky down from the kapok tree, used for insulation, life jackets, and so forth) and of gum from the acacia gum tree are exported. Skins of ostriches, crocodiles, and snakes are used for making handicrafts that are exported to Europe. Fish from the Niger River and Lake Chad are exported southward to the coastal countries.

Agriculture. Agriculture and agricultural products constitute the largest sector of Niger's economy in terms of the number of persons employed and the percentage of gross national product (GNP). Millet and sorghum, the main food crops, are grown in the south, as are cassava and sugarcane. Rice is grown in the Niger River valley. Peanuts are the most important cash crop; other important crops include cotton and pulses.

Livestock is an important sector of the agricultural economy and is a major export. Cattle, sheep, and goats are raised for meat, milk, and hides.

Niger's ability to remain self-sufficient in food and livestock production is closely linked to rainfall, and periods of drought have resulted in shortfalls requiring imports and food aid. To increase production and avoid cereal shortfalls, the government has invested in irrigation projects and an "off-season growing program" of small-scale production and irrigation operations.

Industry. Niger is one of the world's leading producers of uranium, which is mined at Arlit, Akouta, and Tassa. Extraction at the Arlit site is undertaken by the French-controlled Société des Mines de l'Aïr (SOMAIR). The second major mining concern, the Compagnie Minière d'Akouta (COMINAK), is owned partly by the government of Niger and partly by foreign interests. The Tassa mine opened in 1986 and is operated by SOMAIR. The uranium industry was seriously affected by the fall in uranium prices in the early 1980s. Development of additional sites is dependent upon an increase in world uranium prices.

Some manufacturing industries have been established, mostly at Niamey. They produce chemicals, food products, textiles, farm equipment, and metal furniture. There are many small craft industries in the principal towns.

Imported petroleum, supplemented by locally mined coal, is used to generate about half of Niger's electricity, and the remaining amount is imported from Nigeria. The Office of Solar Energy has produced solar batteries, which are used in the country's telecommunications network, and peanut shells have been experimentally used to supplement hydrocarbon fuels since 1968. Wood is the traditional domestic fuel.

Transportation. While the economically active zone of Niger runs from east to west across the southern part of the country, the principal lines of communication run southward toward the coast. The two ports used by Niger—Cotonou in Benin and Lagos in Nigeria—are each more than 600 miles away, and Niger possesses no railroad. Traditional systems of transport and communication are still largely relied upon. These include camel caravans in the northern Sahel region, canoes on Lake Chad and the Niger, and individual travel on horseback or on foot. Only a small tonnage of goods is transported.

Trucks maintain transport communications between Maradi and Zinder in Niger and Kano in Nigeria, and between Niamey and Parakou in Benin. A road completed in 1981 connects the uranium-producing centres of Arlit and Akouta to Nigerian transport links. The principal west–east road axis enters the country from Gao in Mali, runs on the banks of the Niger as far as Niamey, and then continues eastward to Nguigmi on Lake Chad. From this

(margin note, left column) The private sector of the economy

(margin note, right column) Roads

central route, roads branch off southward. Toward the north, routes running via Tahoua and Tânout converge near Agadez, linking Niger to Algeria via Tamanrasset.

Air Niger is responsible for domestic air services linking the country's airports, including those of Tahoua, Maradi, Zinder, Agadez, Diffa, and Arlit. Niamey has an international airport.

Administration and social conditions. *Government.* The constitution promulgated in November 1960, which established a presidential regime, was suspended after the military coup of April 1974. The 14-year ban on political parties was abolished in 1988 (although the transition to democracy remained tenuous thereafter). Until 1989, executive power was held by a Supreme Military Council composed of army officers. The 1992 constitution established a new legislative National Assembly. The president is head of state and appoints the prime minister. Niger's first multiparty elections were held in 1993.

Niger maintains a Supreme Court and a Court of State Security. At lower levels are the Court of Appeal, district courts, and justices of the peace. There are separate labour and assize courts.

Division into *départements* — Agadez, Diffa, Dosso, Maradi, Niamey, Tahoua, Tillabéry, and Zinder — each of which is administered by a prefect. Each *département* is divided into several *arrondissements*.

Education. Education in Niger is free, but only a small proportion of children attend school. Primary and secondary schools and teacher-training colleges are the responsibility of the Ministry of National Education. Other ministries are responsible for technical education. Niger has one of the lowest adult literacy rates in western Africa, and literacy programs are conducted in the five principal African languages. Niamey has a university, and the Islāmic University of Niger at Say opened in 1987.

Health and welfare. The general state of health in the country is poor, and health care facilities are inadequate, especially in rural areas. The infant mortality rate, at about 150 per 1,000 live births, is one of the highest in western Africa. Health services concentrate on the eradication of certain diseases in rural areas, as well as on health education. Campaigns have been successfully waged against sleeping sickness and meningitis, while vaccinations against smallpox and measles are also administered. Other diseases, however, such as tuberculosis, malaria, and leprosy, remain endemic. Antituberculosis centres are located at Niamey, Zinder, and Tahoua. Lack of finances and shortage of trained personnel remain the principal obstacles to the improvement of health conditions.

Cultural life. Niger forms part of the vast Sahelian cultural region of western Africa. Although the influence of Islām is predominant, pre-Islāmic cultural traditions are also strong and omnipresent. Since independence, greater interest has been shown in the country's cultural heritage, particularly with respect to traditional architecture, handicrafts, dances, and music. With the assistance of the United Nations Educational, Scientific and Cultural Organization, a regional centre for the collection of oral traditions has been established at Niamey. An institution prominent in cultural life is the National Museum at Niamey.

For statistical data on the land and people of Niger, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR. (Di.L./Ed.)

HISTORY

One of the central themes of the history of Niger is the interaction between the Tuareg (and also Tubu) nomads of the vast Saharan north and the agriculturalists of the sedentary south — the interaction, that is, between opposed yet complementary ways of life and civilizations. Among the agriculturalists the main ethnic groups are the Songhai-Zerma in the west, the Hausa in the centre, and the Kanuri in the east. The Hausa have always been the most numerous. They constitute nearly half of the total population of Niger.

In the 14th century (possibly also earlier and later) the Tuareg-controlled kingdom of Takedda, west of the Aïr Massif, played a prominent role in long-distance trade, notably owing to the importance of its copper mines.

Copper was then used as a currency throughout western Africa. Archaeological evidence attests to the existence of communities of agriculturalists, probably Songhai-speaking, in this region, which is now desert, at the time of the kingdom of Takedda. Takedda was succeeded at an unknown date by the sultanate of Agadez.

The kingdom of Takedda

For many centuries the southeastern third of present-day Niger constituted one of the most important provinces of the Kanuri empire of Bornu. The might of Bornu was based on the control of a number of salt-producing sites and of long-distance trade, notably along the string of oases between Lake Chad and the Fezzan via Kawar.

The great drought of about 1735–56 — the prelude to the present dry cycle, which set in about 1880 — had an adverse effect upon the natural environment. This may explain why both the communities of agriculturalists west of Aïr and the oases between Lake Chad and Kawar disappeared. It may perhaps also explain in part why the Tuareg were able to extend their control over a fair portion of the sedentary south.

By the time of the colonial conquest, the disparate regions the French molded into an entity known as Niger may be best described as an assemblage of peripheral borderlands. As borderlands, however, these regions had played a significant role as zones of refuge — the west after 1591 and the Moroccan conquest of the Songhai empire and the Hausa region much later, after the 1804 Fulani jihad in central Hausaland (*i.e.,* present-day northern Nigeria). In both cases the refugees were people who had lost in the military as well as the religious struggles of their respective homelands. Thus both regions became bastions of "traditionalism" in the face of partly alien conquerors attempting to impose Islām.

The French conquest began in earnest only in 1899. It nearly met with disaster owing to the local population's determined resistance against the notorious expedition in 1899 led by the French officers Captain Paul Voulet and Captain Charles Chanoine. It was only in 1922, after the severe drought and famine of 1913–15 and the Tuareg uprising of 1916–17, that the French felt safe enough to establish a regular administration under civilian control. By then the power of the Tuareg had been broken.

As elsewhere, the peace in French West Africa (*pax gallica*) meant among other things the rapid spread of Islām, a steep demographic increase, and, although exclusively among the Hausa, the extension of cash crop cultivation. The Songhai-Zerma, on the other hand, responded to the French tax demands by engaging themselves as seasonal labourers in the coastal regions.

Through the reforms of 1946, France's African subjects in theory were granted full citizenship. Thus Niger, along with the other colonies (renamed "overseas territories") of black Africa, was represented in the French Parliament. Consultative-legislative assemblies were also set up locally. These reforms secured the ascent of a tiny new elite, the so-called *évolués* — *i.e.,* those who had been trained in French schools. Many were descendants of former slaves, and most were Songhai-Zerma. Indeed, the people of the west had proved to be far more open to European influence than, for instance, the Hausa.

At least until 1954–55 the French administration (headed for 12 years by Governor Jean Toby) remained firmly in control of the political situation. The first local executive was established in 1957. Its head, the left-wing trade unionist Djibo Bakary, advocated a no vote in the referendum of 1958. However, 72 percent of the votes cast were in favour of a continued link with France.

Nevertheless, under Bakary's successor, his cousin and fellow Songhai-Zerma Hamani Diori, independence was proclaimed on Aug. 3, 1960. Diori, who set up a single-party dictatorship, was toppled in a coup in 1974. There followed a military dictatorship headed first by Seyni Kountché (until his death in 1987) and then by Ali Seibou. Mahamane Ousmane of the Social Democratic Convention became president in the country's first multiparty presidential elections in 1993.

Independence

The peanut boom in the 1950s, the relatively favourable climatic conditions between the late 1930s and the 1970s, and the uranium boom in the 1970s raised some hopes for

the future. These hopes were largely thwarted, however, notably by a military coup in 1996 that brought to power the ineffective government of Colonel Ibrahim Baré Maïnassara. Baré's assassination in 1999 and the subsequent renewal of democratic government under President Tandja Mamadou did little to shore up the country's confidence in its leaders, who were hard pressed to undo the harmful effects of economic mismanagement compounded by years of drought, ongoing desertification, and political militancy among the country's Tuareg population.   (F.F./Ed.)

For later developments in the history of Niger, see the BRITANNICA BOOK OF THE YEAR.

Senegal

Situated at the western extremity of Africa's tropical zone, the Republic of Senegal (République du Sénégal) has an area of 75,955 square miles (196,722 square kilometres). It is bounded to the north and northeast by the Sénégal River, which separates it from Mauritania; to the east by Mali; to the south by Guinea-Bissau and Guinea; and to the west by the Atlantic Ocean. The Gambia constitutes a finger of territory 20 miles (32 kilometres) wide and 200 miles long that thrusts from the coast eastward into Senegal along the Gambia River.

Senegal—which gained its independence in 1960, first as part of the short-lived Mali Federation and then as a sovereign state in its own right—is among the principal producers of peanuts (groundnuts). Although the economy is planned, the moderate controls to which it is subjected are applied in a flexible rather than an authoritarian manner. Private investors, whether foreign or Senegalese nationals, are encouraged to establish new enterprises; an investment code grants tax exemptions and permits the withdrawal of profits. Nationalization has in general been avoided, and indeed the privatization of the few state-owned industries began in the 1990s. The economic life of Senegal is characterized by its membership in the Franc Zone, as a result of which the country benefits from French financial support. The official language of the country is French.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Senegal is a flat country, lying in the depression known as the Senegal-Mauritanian Basin. Elevations of more than about 330 feet (100 metres) are found only on the Cape Verde Peninsula and in the southeast of the country. The country as a whole falls into three structural divisions. These are: first, the Cape Verde headland, which forms the western extremity and consists of a grouping of small plateaus made of hard rock of volcanic

Structural divisions

Shostal Associates/Superstock

Faidherbe Bridge, spanning the mouth of the Sénégal River, at Saint-Louis.

origin; second, the southeastern and the eastern parts of the country that consist of the fringes of ancient massifs contiguous with those buttressing the massif of Fouta Djallon on the Guinea frontier, with the highest point reaching an elevation of 1,640 feet; third, an immense but shallow basin lying between Cape Verde to the west and the edges of the massif to the east.

Washed by the Canary Current, the Atlantic coast of Senegal is sandy and surf-beaten. Like the rest of the country, it is low except for the Cape Verde Peninsula, which represents the westernmost point of the African continent and which shelters Dakar, one of the finest ports in Africa. To the south of the peninsula, the surf on the coast is less heavy. To the south of the Saloum River mouth, the coast consists of rias (drowned valleys) and is increasingly fringed with mangroves.

Drainage. The country is drained by the Sénégal, Saloum, Gambia, and Casamance rivers, all of which are subjected to a climatic regime characterized by a dry season and a rainy season. Of these rivers, the Sénégal, which rises in the Fouta Djallon highlands of Guinea and long has been the main route providing access to the interior, is the most important. After traversing the old massifs the river rapidly drops downward before reaching Senegalese territory. At Dagana it forms the so-called False Delta, which supplies Guiers Lake on the left bank. At the head of the delta is the town of Richard Toll (the Garden of Richard), named for a 19th-century French nursery gardener. The slope of the land is so gentle on this stretch of the river that at low water salty seawater flows about 125 miles upstream. The island on which the town of Saint-Louis stands, at the mouth of the river, is situated a short distance from the sea in the False Delta, whose true mouth lies 10 miles to the south.

The False Delta of the Sénégal

Soils. Despite its apparent uniformity, Senegal contains a great diversity of soils. These fall generally into two types—the valley soils and those found elsewhere.

The soils of the Sénégal and Saloum river valleys, in their middle courses, are alluvial and consist of sandy loams or clays. Near the river mouths the soils are salty and favourable for grazing. Similar conditions are associated with the Gambia and Casamance rivers, except that near their mouths the banks are muddy, while their upper courses have sandy clay soils.

Many different types of soils are found in the various regions. In the northwest the soils are ochre-coloured and light, consisting of sands combined with iron oxide. These soils, called "Dior soils," constitute the wealth of Senegal; the dunes they form are highly favourable to peanut cultivation, while the soils between the dunes are suitable for other food crops, such as sorghum. In the southwest the plateau soils are sandy clays, frequently laterized (leached into red residual iron-bearing soils). In the centre and the south the country is covered by a layer of laterite hidden under a thin covering of sand. These soils afford only sparse grazing during the rainy season. In Casamance heavily leached clay soils with a high iron oxide content predominate. Whether they are deep, as in western Casamance, or shallow, as in the southeast of the region, they are suitable for cultivation.

Climate. Senegal's climate is conditioned by two major factors: first, the tropical latitude of the country and, second, the seasonal migration of the intertropical convergence zone (ITCZ)—the line, or front, of low pressure at which hot, dry continental air meets moist oceanic air and produces heavy rainfall. The prevailing winds, characterized also by their area of origin, fall into two categories— those that are dry, originating in the continental interior, and the moist maritime winds that bring the rains.

The dry winds consist of the northeast trade winds, known in the winter and spring when they are strongest as the harmattan; they bring no rains at all, apart from a very light precipitation which, to the Wolof people of Senegal, is known as the "Heug." The rain-bearing winds blow primarily from the west and northwest. Beginning in June with the northward passage of the ITCZ these winds usher in the summer monsoon. As the ITCZ returns southward beginning in September, the rainy season draws to a close. The slow north–south migration of the ITCZ results in

a longer, heavier rainy season in the southern part of the country.

From the combination of these various factors, three principal climates may be distinguished, each of them associated with a characteristic type of vegetation.

The coastal (Canarian) climate occurs along a coastal strip about 10 miles wide running from Saint-Louis to Dakar. Its winters are cool, with minimum temperatures reaching about 63° F (17° C) in January and maximum temperatures in May not exceeding 81° F (27° C). The rains begin in June, reach their height in August, and cease in October. The average rainfall is about 20 inches (500 millimetres).

The Sahelian climate occurs in a zone bounded to the north by the Sénégal River and to the south by a line running from Thiès (a town on Cape Verde Peninsula) to Kayes in the neighbouring country of Mali. The month of January is cool, especially in the mornings before sunrise, when the temperature drops to about 57° F (14° C); afternoon temperatures, however, may rise to higher than 95° F (35° C). In May, minimum temperatures do not fall below about 72° F (22° C), while maximums often rise above 104° F (40° C). The dry season is quite distinct and lasts from November to May. Certain places, such as Podor and Matam, are particularly noted for their dryness and heat. Between July and October the rainfall averages about 14 inches, moderating the temperature somewhat. Maximum temperatures at this season reach about 95° F (35° C).

The Sudanic climate occurs in the remainder of Senegal. Regional nuances are in evidence. Thus, from north to south three climatic subdivisions may be recognized, each of which is characterized by the amount of average annual rainfall. First, in the Kaolack–Tambacounda subdivision, annual rainfall averages between 29 and 39 inches, occurring on about 60 days between June and October. Cultivation without irrigation is possible in this region. Second, in the Gambian region, the rainfall frequently amounts to 50 inches, resulting in the growth of a continuous belt of light forest and patches of herbaceous undergrowth. Third, in the Casamance region, rainfall everywhere exceeds 50 inches, falling on 90 days of the year. The forest is dense and green and is continuous, without undergrowth. Oil palms, mangroves, and rice fields are characteristic of this climate zone. The Sudanic climate in general is very hot, humid, and uncomfortable. The town of Kaolack, for example, has average afternoon temperatures near 100° F (38° C) throughout the year and is rendered yet more oppressive by the salt wind.

Animal life.   While it is true that large mammals have disappeared from the western part of the country, owing to human settlement, such animals as elephants, antelopes, lions, panthers, cheetahs, and jackals may still be encountered in the interior. Herds of warthogs abound in the marshes, especially those of the False Delta. Hares are ubiquitous, and monkeys of all types congregate in noisy bands, above all in the upper Gambia and upper Casamance river valleys. Among the great numbers of birds the quelea, or "millet eater," which is destructive of crops, may particularly be noted, as well as the partridge and the guinea fowl. Reptiles are numerous and include pythons and cobras and other venomous snakes. Crocodiles, hippopotamuses, and turtles are found in the rivers. The rivers and the coastal waters are rich in fish and crustaceans.

Settlement patterns.   While such physical factors as geology, soil, climate, and vegetation have resulted in regional differentiation, man has also been a determining factor in the delimitation of different regions, each marked by a traditional type of human settlement. Thus from north to south five principal traditional regions may be distinguished.

The Ferlo region is the central region of Senegal; very extensive, it is distinguished by its semidesert aspect and by the poverty of its soils. Vegetation appears only in the south, the north consisting of the Sahelian type of savanna parkland (an intermediate zone between the Sahara and the savanna proper); it affords light grazing for the flocks of nomadic Fulani (Peul) pastoralists.

Fouta-Toro is based upon the Sénégal River, extending approximately from Bakel in the east to Dagana in the north and consisting of a strip of territory that is relatively densely inhabited. Cultivated lands, which are watered by the river and its tributaries in the dry season, are of importance thanks to highly developed agricultural and pastoral use of the soils and vegetation. Most of the region is inhabited by Tukulor people. Fouta-Toro is bounded to the west by the False Delta, also known as the Oualo, which is peopled by the Wolof, who cultivate millet and carry on stock raising, employing Fulani shepherds.

The Dianbour, Cayor, Djolof, and Baol region is a diverse area situated between the Ferlo region and the Atlantic and extending from the Oualo in the north to the Cape Verde Peninsula in the south. The soils are sandy, the winters cool, and peanuts are the primary crop. The population is as diverse as the region itself and includes Wolof in the north, Serer in the Thiès region, and Lebu on Cape Verde.

The Sudan region is bounded by Cape Verde to the northwest, the Ferlo to the north, and the lower Casamance Valley to the southwest. It is composed of the following subregions—the "Little Coast," Sine-Saloum, Rip, Yacine, Niani, Boundou, Fouladou, and the valleys of the Gambia and upper Casamance rivers. In general, the region benefits from ample rainfall, which becomes abundant toward the south. The clayey soil is suitable for agriculture, despite the lateritic crust that appears intermittently. The region, as a result, is relatively densely populated. The estuaries are muddy and salty, with marshy saline depressions known as *tannes* occurring occasionally. The region as a whole is inhabited by a very diverse population composed of all the ethnic groups living in Senegal; the majority are, however, Malinke (Mandingo).

The lower Casamance region is small but strongly characterized. It is covered by dense vegetation of the Guinean type. Mangroves, oil palms, and raffia palms predominate. The rainy climate favours the cultivation of rice, which has long been a specialty in this part of the country.

The great majority of the Senegalese population lives in the countryside. There are numerous villages, each with an average population of a few hundred persons. Usually each village has a shaded public gathering place, a mosque, and a water source, whether a well, a spring, or a small stream. The village is administered by a chief who is either traditionally nominated or appointed by the government. Religious life is directed either by a person literate in Arabic, called a marabout, or by a leading sorcerer. Various types of village may be distinguished, according to ethnic characteristics.

Whether it is situated in the western Ferlo or the Cayor regions, the Wolof village is small, being inhabited by about a hundred farmers. The houses are built of locally obtained materials. Each village may easily be moved from place to place, as the topography provides no natural obstacles to this. Harvests are kept in straw granaries, located far from the compounds for fear of fires. In the eastern Saloum region, the Wolof village is surrounded by three concentric zones of vegetation. The first of these—the inner zone—consists of fields and vegetable gardens and is known as the Tol-keur (literally "kitchen garden"). The second circle consists of land that has been exhausted, except for peanut cultivation, and it is known as the Diatte. The third, the farthest from the village, is the Gor, in which cereal crops are cultivated.

The typical village of the Sudanic region of Casamance consists of a Malinke agglomeration; it is a heritage from the epoch when the Sudanic peoples conquered the region. Each village has between 200 and 300 inhabitants living in enclosed compounds and crowded together in geometrically aligned rectangular huts. Agriculture and stock raising are the principal activities. The chief of each village is generally a marabout, conservative in his ways.

The Serer village differs from the Wolof and Malinke village because of its family compounds, called M'Binds, being loosely dispersed; each M'Bind is autonomous. On the islands at the mouth of the Saloum River, the houses of the Serer Nyiominka people are solidly built and trim. The granary is located in the compound.

Rainfall in the Sudanic area

Rural settlement

Diola villages contain 5,000 or more people. Like those of the Serer, the compounds are not grouped in any distinguishable hierarchy. These villages are characteristically built on the edge of a plateau or on ground overlooking the rice fields, which are associated with Diola life. Their houses are the best-built and most permanent village dwellings in Senegal. On occasion they constitute veritable fortifications, as in the Thionck-Essil and Oussouye regions; the villages of the Essil region also can be quite sophisticated, with many of them equipped with rainwater-catchment systems. Diola and Serer villages have no chiefs with authority or prestige comparable to those of Wolof or Malinke villages. (Ca.C.)

Major towns

The towns of Saint-Louis (founded in 1659) and Dakar (1857) are the oldest in Senegal; Dakar replaced Saint-Louis as the capital in 1902. Other towns, founded more recently and of colonial origin, typically developed as collection points for the peanut trade and later evolved into urban centres. These towns were often stops along the railroad lines, as at Thiès, Tivaouane, Mékhé, and Louga (between Dakar and Saint-Louis), or Khombole, Bambey, Diourbel, Gossas, Kaffrine, and Koungheul (between Thiès and Kayes, Mali). Certain ports also became towns: among these are Kaolack, Foundiougne, and Fatick (on the Sine-Saloum rivers), and Ziguinchor, Sédhiou, and Kolda (on the Casamance River). With the exception of Dakar, Saint-Louis, Rufisque, Thiès, Kaolack, and Ziguinchor, these towns have remained rural in character. Furthermore, every town—including Saint-Louis, Rufisque, and Gorée, which had great importance in the past—today depends on the Dakar metropolis, where some one-fifth of all Senegalese live.

Apart from the division of the countryside into traditional regions, the best agricultural lands in Senegal are concentrated in the west and in the river valleys. The remainder of the land becomes increasingly poor and less settled as one continues toward the north or the east.

The people. *Linguistic composition.* Some 39 languages are spoken in Senegal, including French and Arabic. Linguists divide the African languages found there into two families: Atlantic and Mande. The Atlantic family, generally found in the western half of the country, contains the languages most widely spoken in Senegal, including Wolof, Serer, Fula, and Diola. Mande languages are found in the eastern half and comprise Bambara, Malinke, and Soninke.

Ethnic composition. The Wolof, who predominate in the sandy western region, represent more than one-third of the total population, and their language is the most widely used in the republic. In the Cayor district they are members of the Tijānī Muslim brotherhood. The other Islāmic brotherhood in Senegal, that of the Murīdīyah, is also highly influential, and as agriculturists, its members have migrated southward with the expansion of peanut cultivation in the region.

The Serer, who are closely related to the Wolof, are densely settled in the western part of the southern Ferlo region. They are experienced farmers, practicing both cultivation and cattle raising. Originally adherents of traditional religion, they are increasingly converting to either Islām or Roman Catholicism.

The Fulani are also Muslim and are distributed throughout Senegal, but they are found particularly in the Ferlo, upper Casamance, and Oualo regions, where their settlements are substantial. Although characteristically nomadic pastoralists, many of them have become settled agriculturists, especially in the Fouta Toro (Fouta) region and on the Senegal-Guinea border.

The Tukulor are often hard to distinguish from the Wolof and the Fulani, for they have often intermarried with both. Named for the ancient realm of Tekrur, the Tukulor live primarily in the middle course of the Sénégal River valley, but they are also found in dispersed groups along the Gambia and Saloum rivers. The Tukulor were the first Senegalese people to become Muslim, having accepted Islām probably in the 11th century; many are literate in Arabic, owing to its use in Islāmic ritual and scholarship. Although primarily farmers, they are increasingly migrating to the towns, particularly to Dakar and Saint-Louis.

The Diola occupy the lower Casamance valley and the southwest of the Gambia valley. They are skilled farmers specializing in growing rice and cultivating peanuts and millet, the latter two crops prominent among the Diola living farther inland. In the Fogni district some Diola are Muslim, but the majority follow traditional religions, while a few have converted to Christianity.

The Malinke, followers of Islām, came originally from the Niger River valley and have spread out into various regions of Senegal, especially into the Gambia, upper Casamance, and Saloum valleys, where most make their living as farmers and traders.

The Soninke, also Muslim, are a minority group of Berber descent and represent an extension into Senegal of the Malinke families of Mali. They are in the process of abandoning an unfruitful agricultural terrain in order to migrate toward the towns, where they often become small traders.

The numerically less significant Senegalese comprise such peoples as the Mauri, who live especially in the north of the country, where they are stock raisers or traders; the Lebu of Cape Verde, who are fishermen and often wealthy landowners; and the Basari, people of ancient origins who mostly are found in the rugged and rocky highlands of Fouta Djallon.

The economy. Three factors affect economic life in Senegal. The first is the division of the country into two regions—the small western region, which is wealthy and dynamic, and the rest of the country, which remains poor and economically stagnant, dependent upon a subsistence economy. The second factor is the persistence of a single-cash-crop economy. The government, however, has attempted to diversify both cash crops and subsistence agriculture by expanding into commodities such as cotton, millet, rice, corn (maize), and sugarcane. The third factor is tourism, which has become increasingly important to the economy.

Before Senegal's independence from France in 1960, the economy was mostly in the hands of the private sector. Since the economic activity largely revolved around the peanut trade, the large French companies that marketed the crop also controlled the importation of European manufactured goods. After independence the Senegalese government created a state agency responsible for virtually all aspects of the peanut trade; in consequence, though the private sector remained important, it received its principal impulse from the state. An investment code, composed of various guarantees and long-term tax concessions, has attracted capital investment from many quarters.

The public sector is especially important, because Senegal, for historic reasons, has never had a middle class in the Western sense. The intervention of the state, moreover, is not a recent phenomenon; it had occurred during the colonial era but became more prevalent after independence with the creation of the National Organization of the Rural Sector. Apart from buying and selling peanuts, rice, and millet, the organization also sells fertilizer, seed, tools, and equipment and remains the backbone of the government's policy of "African socialism."

The National Organization of the Rural Sector

In the 1980s and continuing through the '90s, the government began to move away from state intervention in the economy and to encourage the reintroduction of private initiatives. As part of this general trend the peanut industry moved toward private organizations made up of the producers themselves. Privatization was also the trend among other industries in Senegal.

Most governmental revenue is obtained indirectly from local taxes on alcohol, gasoline, tobacco, firearms, automobiles, and commerce. Land, professional licenses, profits, and income are directly taxed.

Since the late 1970s a population explosion, uncontrolled migration to the city, and declining prices for primary materials have depressed the economy. Only substantial foreign aid has prevented a decline in the standard of living. The transportation infrastructure has also rapidly deteriorated, although the government, with foreign assistance, has tried to address this problem.

Tourism is the country's primary source of foreign exchange, and Senegal is the most visited country in West

Africa. Although most of the tourists are Europeans, the government has tried to attract others, especially Americans. Gorée Island, site of a former slave warehouse, is a popular destination.

Resources. Senegal's known mineral deposits are only of minor importance and consist primarily of phosphates of lime, located at Taïba, near Tivaouane, about 60 miles (100 km) northeast of Dakar, and aluminum phosphates at Palo, near Thiès. Significant mineral reserves include petroleum deposits discovered off the Casamance coast and high-grade iron-ore reserves located in the upper Falémé River valley. The saltworks of Kaolack have considerable production potential. Production of gum arabic, which is obtained from acacia trees, is of lesser significance, and other forest products also have limited commercial value. The herbaceous vegetation is nevertheless conducive to livestock raising, and by improving the grazing land available, Senegal has the potential to increase significantly the number of its cattle herds.

The waters off Senegal, particularly those at some distance from the shore, are rich in economically significant fish, although the coastal waters are also known for their large variety of fish; in this respect Senegal is better endowed than most other African countries on the Atlantic seaboard.

Agriculture and fishing. Agriculture occupies about two-thirds of the economically active population and provides the basis for industry as well. Although a certain balance is maintained between livestock raising and peanut cultivation, it is the latter that earns the foreign exchange the country needs and sparks the most economic activity throughout Senegal; the resulting wealth has led to the development of smaller towns and the establishment of river ports at Kaolack, Foundiougne, Fatick, Sédhiou, and Kolda. Dakar's economic livelihood, in fact, rests largely with the peanut crop.

Several other food crops also are grown. Extensive acreage is devoted to sorghum and plants from the *Pennisetum* genus of Old World grasses. Rice is cultivated both in naturally wet areas and by irrigation, although its large-scale cultivation is restricted to the lower Casamance valley and the lower Sénégal River valley below Richard Toll. In addition, corn, cassava (manioc), beans, and sweet potatoes are grown in significant quantities.

The climate and the savanna type of vegetation encourage the raising of livestock—including cattle, goats, sheep, horses, donkeys, camels, and pigs—which is carried on in almost all regions but is especially characteristic of the north. Stock raising is not a major source of income for the farmer, however; the meat is consumed locally, and only the hides and skins are exported.

Although many fish are obtained from the rivers, the greater part of the catch is obtained from the sea. Fishing products now lead all exports in terms of value, the result of many years of government efforts in building up the industry.

Industry. Industrial production in Senegal is more developed than in most western African countries. Both processing and handicraft industries are well established. Most of the former is located in the Cape Verde region, where plants produce peanut oil. In good years, Senegal is the leading producer of peanut oil in French-speaking sub-Saharan Africa. However, the world market for this product is decreasing, and the government's push for the greater privatization of markets has led to cooperatives selling directly to local oil producers in Dakar, Rufisque, Kaolack, Diourbel, and Ziguinchor. In addition, there are fish canneries, a shoe factory, and a cement manufacturing plant, the latter two located in Rufisque. Other industrial establishments, all of which are located in Dakar, include flour mills, a textile plant, a sugar refinery, a tobacco factory, and a brewery, in addition to a naval shipyard, chemical plants, and an automobile assembly plant. Traditional handicrafts are produced mainly in Dakar and Saint-Louis, home to the most skilled craftsmen. Mineral production is of lesser significance to the national economy and consists of lime phosphates and aluminum phosphates.

Electric energy is produced and distributed by the Senegalese Electric Company (la Société Sénégalaise d' Electricité [SENELEC]). Since 1998 SENELEC has been partially privatized. Before the 1980s all energy produced in Senegal was generated by thermal plants. Cheaper hydroelectric energy became available with the construction of the three-nation hydroelectric projects on the Sénégal River, with dams at Diama in Senegal (completed in 1985) and Manantali in Mali (completed in 1988). The latter has also provided water for large areas of newly irrigated land.

Finance and trade. Senegalese finance is still dominated by connections established during the colonial period when Senegal was the principal territory of French West Africa. Currency is issued by the Central Bank of West African States, an agency of the West African Monetary and Economic Union, comprising countries that were once French colonies in Africa. Other state and private banks exist, including several Islāmic ones. Goods from countries within the French economic community—whose currency is based on the franc—incur a simple fiscal tax, whereas those from European Union countries receive a preferential tariff.

The value of imports is usually greater than that of exports, and Senegal generally has a significant balance-of-trade deficit. The principal imports are agricultural products, capital goods, and petroleum products, and exports include seafood, chemical products, peanut oil, and phosphates. France is the primary trading partner. Other trading partners include the United States, Germany, Spain, Mali, and Nigeria.

Transportation. The transport network has developed primarily in the western part of the country within the area bounded by Saint-Louis, Kaolack, and Dakar. About half of Senegal's extensive road network is passable year-round. Construction began in 1996 on what eventually will be a transcontinental highway linking Egypt to the Atlantic coast through Chad, Mali, and Senegal.

The rail system includes a line from Saint-Louis to Dakar, with a branch line running from Louga inland to Linguère, and a line from Dakar to the Niger River at Koulikoro, Mali. Locomotives are run entirely on diesel fuel. The network is being rehabilitated and expanded, and responsibility for the operation has been given to a Canadian company. Phosphates represent the great bulk of freight carried by rail.

Senegal's three seaports are Kaolack, Ziguinchor, and Dakar. Only Dakar is an international port; the others are limited to handling local traffic. Dakar is one of the busiest ports in western Africa and accommodates ships up to 100,000 tons in nearly 50 berths along 6 miles of quay. The quays provide refrigerated facilities that harbour 1,000 fishing boats each year. At the end of 1988 a terminal for handling containers was opened that considerably cut costs and only reinforced the important position of this port; these facilities have since been expanded.

The international airport of Dakar-Yoff near Dakar is served by a number of airlines. Its three runways can accommodate any kind of aircraft. Construction began in 1999 on a second international airport at Keur Massar, about 30 miles east of Dakar. Airports at Saint-Louis and several other cities handle domestic service.

Since the end of the 19th century the rivers, of which the Sénégal has always been the most important, have lost much of their importance as transportation arteries. The Sénégal is navigable year-round from Saint-Louis to Podor by boats with drafts of about three feet. Navigating the river has been facilitated by the completion of the Diama and Manantali dams, and the Sénégal will be navigable as far as Kayes, Mali, when the last phase of the Manantali project is complete. Activity on the Saloum River centres on peanut shipping from Kaolack, and traffic on the Casamance is to and from the port of Ziguinchor.

Administration and social conditions. *Government.* The first constitution of Senegal was promulgated in 1963 and has been revised many times. It proclaims fundamental human rights; respect for individual and collective property rights; political, trade-union, and religious freedoms; and a democratic and secular state.

The constitution provides for a strongly centralized presidential regime elected by direct universal adult suffrage.

River transport

The president, who can be elected to two seven-year terms, appoints the prime minister. Ministers are appointed by the prime minister in consultation with the president. The legislature consists of a National Assembly and a Senate. The National Assembly comprises 140 members who serve five-year terms, half elected from an at-large list of candidates and half by proportional representation. The Senate, first elected in January 1999, consists of 60 members who also serve five-year terms and represent territorial regions, including for Senegalese living overseas. Judicial, executive, and legislative powers are separated.

Senegal is divided into 10 *régions,* which in turn are divided into *départements* and *arrondissements.* Each *région* is administered by a governor whose role is coordinative and who is assisted by two deputy governors, one dealing with administration and the other with development. Regional assemblies, the powers of which were increased in 1996, are composed of general councillors responsible for local taxation. In each *département* the prefect represents the republic, as do the ministers. There are also autonomous urban communes. Dakar is governed by an elected municipal council.

Justice is administered in the *départements* by justices of the peace and in the *régions* by courts of first instance. Criminal cases are judged by assize courts held at Saint-Louis, Kaolack, Ziguinchor, and Dakar. Dakar is also the seat of the Court of Appeal.

The Senegalese played a pioneering role in the development of a modern political system in the territories of French West Africa. At first, political life was of concern only to an elite consisting of the intellectuals, the traditional chiefs, and above all the inhabitants of the four communes—Saint-Louis, Dakar, Rufisque, and Gorée—who had been French citizens since 1916. After World War II universal suffrage was introduced in stages, and the electorate increased from 890,000 voters in 1958 to 1,932,265 in 1988. Senegalese citizens now participate in the elections of the president, members of the National Assembly and Senate, and regional and municipal councillors.

The electorate

Unlike most African states, which each tend to have only a single political party, Senegal has a solidly entrenched multiparty system that is guaranteed by constitutional provision. Elections are contested by several parties representing a wide range of political views. In spite of this diversity, party politics has been dominated by the Socialist Party (until 1976 the Senegalese Progressive Union) since national independence.

In addition to political-party and trade-union activities, other institutions also permit participation in the political process. These include societies for mutual assistance, which are organized at the regional as well as village level, youth associations, and religious groupings, which are most influential. Muslims, particularly Sunnites, are aware of their political power and have even called for the establishment of an Islâmic state based on Islâmic canon law, or Sharî'ah. The government remains committed to a secular state.

Education. Western-style education has existed in Senegal since the 19th century; its first goal was to train the Senegalese in French culture and to help with colonial administration. Since independence Senegal has made particular efforts to increase school enrollment in rural areas, although with limited success; the literacy rate remains one of the lowest in the world. Among the secondary schools, the Faidherbe Lycée at Saint-Louis and the Van Vollenhoven Lycée at Dakar are the most renowned and the oldest. Technical education is expanding and is provided by institutions in Dakar, Saint-Louis, Diourbel, Kaolack, and Louga.

A regional centre for education

Higher education developed from the School of Medicine of Dakar (1918). It achieved full status as a university in the French system in 1957 and became known as the University of Dakar. The name was changed in 1987 to University Cheikh Anta Diop to honour a Senegalese scholar and politician. Following disturbances in 1968, Senegal concluded an agreement with France that emphasized a more African-based curriculum. The College of Sciences and Veterinary Medicine for French-speaking Africa is also located in Dakar, and a polytechnic college opened at Thiès in 1973; the University of Saint-Louis was founded in 1990. These institutions have made Senegal a regional educational centre, and approximately one-fifth of the students attending these schools are foreign, mostly from the French-speaking countries of Guinea, Mali, and Burkina Faso.

Health and welfare. Although Senegal has a considerable range of medical facilities, most of them are concentrated in Dakar and are thus insufficient for the country's health needs. They include hospitals, clinics, maternity homes, and various services specializing in diseases such as tuberculosis, syphilis, and leprosy. The Senegalese Red Cross and the French Overseas Office of Scientific Research and Technology, which cooperates with the World Health Organization, are also active.

Malaria is the leading cause of death by infectious disease in Senegal. There also has been a resurgence in tuberculosis, part of a worldwide trend, but polio, once a significant menace, has been nearly eliminated. Cases of AIDS have been reported in Senegal, but the overall infection rate is not high compared with those of other sub-Saharan countries.

In rural areas, dwellings are usually well constructed and roofed with straw, whereas walls are made of either earth or straw. In more prosperous villages, roofs can also be made of corrugated iron, and walls sometimes of cement brick. Houses in towns are constructed out of cement and have roofs either of tile or of corrugated iron; typically, many families are crowded together in these dwellings. Migration from the countryside has expanded the population of urban areas and resulted in the proliferation of shantytowns.

The standard of living in the countryside is low compared with that of the cities. Manufactured products are less expensive in the cities, which, despite often startling social inequalities, may appear to be a kind of paradise in comparison with the considerably more austere living conditions in rural areas.

Country life, in its traditional communal village form, is still followed by some three-fifths of Senegalese. The extended family lives under the authority of its most elderly member in a compound consisting of a group of thatched dwellings and engages in subsistence agriculture for a livelihood. The influence of the marabouts—interpreters of the Qur'ān—remains uncontested. A money economy is virtually nonexistent, and most transactions are conducted still on the barter system.

City dwellers have a markedly different life, which typifies the modernization of Senegal. To speak of city life, however, is to speak principally of Dakar, because more than half of town dwellers live in the capital. City dwellers earn considerably more money than rural farmers and enjoy better lodging, food, education, and health conditions; they live a life divorced from the traditional values of the communal village. In sum, there are two sides to Senegal today: one with inhabitants in step with modern life and international society and another following a far more traditional and provincial pattern of life that has lost its primary impulse and is growing increasingly stagnant.

Cultural life. Collectivism is dominant in traditional Senegalese life. Although written forms of languages spoken in Senegal have existed for some time, the cultural heritage is contained in oral tradition, mainly preserved by the oldest men of the community. Society is thus hierarchical, with the oldest men at the summit. The traditional Senegalese cultural heritage remains much alive. Rites and initiations are actively practiced in rural areas—for example, by the Basari of Kédougou. Among Muslims, youths must be circumcised before being accorded the responsibilities of adulthood.

The social hierarchy

The arts. Art, sculpture, music, and dance remain typically Senegalese in expression. Sculpture is characterized by abstraction and by the ideogram, whereby the artist deemphasizes the material aspect in order to give free rein to ideas and to feelings; a sculptured gazelle, for example, may be represented solely by its horns and its neck, or an elephant may be depicted only by the immense fan formed

by its ears and its trunk. Similarly, because there is no written music, the imagination of the musician is critical; the griot (a West African troubadour and historian) recites poems or tells stories of warrior deeds that contain a core of ideas around which the griot may improvise. Dance and music also owe much to improvisation, which, combined with rhythm, produces an intense effect upon the entire community.

Senegalese literature is incarnated by Léopold Senghor, the former president, who in 1983 became the first person from sub-Saharan Africa to be elected to the French Academy. A poet as well as a politician, he is associated with Negritude, a philosophy that celebrates the traditional culture of sub-Saharan Africa. In addition to Senghor, writers include Ousmane Socé, David Diop, Alioune Diop, Cheikh Anta Diop, Cheikh Amidou Kâne, Abdoulaye Sadji, Abdoulaye Ly, Ousmane Sembène, and Bakary Traoré, all of whom are known for works that combine intelligence with the flavour of Senegalese life.

Since the first World Festival of Negro Arts was organized at Dakar in 1966, a number of existing institutions have been reoriented toward African traditions, and new institutions such as the Dynamique Museum, the Daniel Sorano Theatre, and the Tapestry Factory of Thiès have also been created; the craft village of Soumbédioune in Dakar has become a centre for Senegalese sculpture and goldsmithing.

The press and broadcasting. Senegal was the first of the former French West African territories to have a press. Daily newspapers include *Le Soleil* and several others. Radio Sénégal broadcasts in French, English, and several African languages; the French-language station Africa No. 1, from Gabon, and Radio France International are also available. Television is prevalent, with stations broadcasting in Arabic, French, English, and such African languages as Wolof. Phone booths and phone stores with facsimile machines exist in rural and urban areas. Internet services are also available.

Sports and recreation. Senegal has one of the most active national sports scenes in West Africa. Dakar has hosted the All Africa Games and several Africa Cup soccer (association football) championships. The country has national men's and women's soccer and basketball teams that rank among the best in Africa. The country has produced some excellent basketball players who have attended U.S. universities. Traditional African wrestling is also extremely popular throughout the country, and Senegalese wrestlers are among the best-known sports figures in the country. Matches are festive and lively occasions, with music, dancing, and praise-singing for the athletes; the actual wrestling bouts, however, are often over within a few seconds.

(Ca.C./A.F.C.)

For statistical data on the land and people of Senegal, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

Senegal has been inhabited since ancient times. Paleolithic and Neolithic axes and arrows have been found near Dakar, and stone circles, as well as copper and iron objects, have been found in the Sine-Saloum region.

The Fulani

The Fulani, often called the Tukulor, occupied the lower Sénégal River valley in the 11th century AD. The name Senegal appears to be derived from that of the Zenaga Berbers of Mauritania and northern Senegal. About 1040, Zenaga Berbers established a Muslim monastery, perhaps on an island in the river; this became the base for the Almoravids, who converted the Tukulor, defeated the Soninke empire of Ghana, conquered Morocco, and crossed into Spain. Between 1150 and 1350 the legendary leader Njajan Njay founded the Jolof kingdom, which in the 16th century split into the competing Wolof states of Walo, Kajor, Baol, Sine, and Salum. Islāmic influence spread throughout the region in varying strength; it gained a new impetus from the later 17th century, and after 1776 Tukulor Muslims established a theocratic confederacy in Fouta Toro (Fouta).

Portuguese navigators reached Cape Verde about 1444; they established trading factories at the mouth of the Séné-

gal, on the island of Gorée, at Rufisque, and along the coast to the south. In the colonial conflicts that took place during the 17th century, their power was superseded by that of the Dutch and then the French.

The French period. A French factory at the mouth of the Sénégal River was rebuilt in 1659 at N'Dar, an island in the river that became the town of Saint-Louis, and in 1677 France took over Gorée from the Dutch. These two communities became bases for French trading companies that bought slaves, gold, and gum in the region and became homes for free Christian Africans and Eurafricans.

After two periods of British occupation, Saint-Louis and Gorée were returned to France in 1816. When attempts to grow cotton near Saint-Louis proved unprofitable, trade for gum in the Sénégal valley was substituted. In 1848 the marginal colonial economy was further disrupted when the Second Republic outlawed slavery on French soil, and the trade in human flesh ground to a halt.

In 1854 Napoleon III granted the request of local merchants for a greater French military presence and appointed Commandant Louis-Léon-César Faidherbe as governor of the region. At the same time, al-Ḥājj 'Umar Tal, a Tukulor, conquered the Bambara kingdom of Kaarta as well as the states of Segu and Macina, but he was unable to control his home territory of Futa-Toro because the French occupied the land. A military stalemate after 1857 led to a truce of coexistence between the two powers, although the French exploited the internal conflicts in the region after 'Umar Tal's death in 1864. When Faidherbe retired in 1865, French power was paramount over most of the territory of modern Senegal, with peanut (groundnut) cultivation and export reaping great economic benefits for the colonists.

In 1879 the French government approved a large program of railway construction (built from 1882–86) in its African colony. One line linked Saint-Louis with Dakar through the main peanut area in Kajor, where commercialization and indebtedness were already disturbing Faidherbe's system of collaboration with indigenous rulers. This policy was reinforced in 1886 when Islāmic legitimacy among the Wolof passed to Amadu Bamba Mbake, who became the spiritual leader of a new fraternity, the Murīdīyah. He exhorted its devotees to discharge their religious obligations by the diligent cultivation of peanuts. Another rail line, the Dakar-Niger line, was not completed until 1923 and facilitated access to the territory formerly controlled by 'Umar Tal. Meanwhile, France was consolidating direct control over the rest of Senegal and its other African colonies. In 1895 Jean-Baptiste Chaudié became first governor-general of French West Africa, and in 1902 its capital moved to Dakar.

Before this new autocratic empire had established its rigid administrative control over such traditional chiefs as it still tolerated, the Third Republic had recognized the inhabitants of Saint-Louis, Gorée, Dakar, and Rufisque, regardless of ethnicity, as French citizens. In 1914 the African electors succeeded in sending Blaise Diagne, an African former colonial official as their deputy to the National Assembly in Paris. In return for assistance in recruiting African soldiers to fight for France in World War I (some 200,000 in all from French West Africa), Diagne obtained confirmation of full French citizenship rights for this urban minority, even if they chose to retain their status under Muslim law. These privileges were lost between 1940 and 1942, when French West Africa passed under control of the wartime Vichy government, but were restored under the Fourth Republic.

Two socialist deputies elected in 1946, Lamine Guèye and Léopold Senghor, at first concentrated on restoring the original French citizenship rights and then extending them to the whole Senegalese population. But political life was increasingly influenced by nationalist movements elsewhere in Africa and Asia, as well as by strong internal tensions, notably those revealed by a sustained railway strike in 1947–48. Senghor, a poet and philosopher who sought some synthesis between an authentic African identity and French civilization, built a strong political position on partnership with the leaders of the Murīdīyah and other socially conservative Muslim orders, but he was increasingly

driven toward claiming political independence. In 1958 the Senegalese electorate accepted his advice to vote in favour of membership in Charles de Gaulle's proposed French Community, but two years later Senegal claimed and received independence (initially within the short-lived Mali Federation).

Independent Senegal. As president, Senghor maintained collaboration internally with Muslim religious leaders and externally with France, which continued to provide economic, technical, and military support. The economy, however, remained vulnerable both to fluctuations in world prices for peanuts and phosphates and to the Sahelian droughts, and the government found it increasingly difficult to satisfy the expectations of the working class and of a rapidly growing student body. Although Senegal remained more tolerant and pluralist than many African states, there were nonetheless encroachments on political freedoms. In 1976, however, Senghor authorized the formation of two opposition parties; Abdou Diouf, to whom he transmitted presidential power in January 1981, tentatively extended these freedoms.

Under Diouf, the Socialist Party (French: Parti Socialiste; PS) maintained Senghor's alliance with the Muslim hierarchies. When the PS secured more than 80 percent of the votes in the 1983 elections, there were complaints of unfair practice, and the eight deputies returned by the Senegalese Democratic Party (French: Parti Démocratique Sénégalais; PDS) of Abdoulaye Wade initially refused to take their seats. Nevertheless, the framework of parliamentary democracy survived the continuing economic stringency of the 1980s. In 1988 Diouf's presidential majority dropped to 73 percent, and the PDS won 17 of the 120 parliamentary seats. Charges of inequity and fraud, and considerable violence, were followed by the declaration of a state of emergency. Wade was imprisoned but was subsequently pardoned.

Diouf found it increasingly difficult to meet prescriptions for economic adjustment while trying to contain social and ethnic pressures caused by falling export values, rising costs of living, and mounting unemployment. The proclamation in 1981 of the Senegambian confederation, established after Senegalese troops marched into The Gambia

to crush a military coup, was abrogated in 1989. The latter year, a long-standing border dispute between Senegal and Mauritania erupted into serious ethnic violence; several hundred Senegalese were massacred in Mauritania, and both countries expelled tens of thousands of expatriates. Senegalese merchants took over many of the businesses previously owned and operated by Mauritanians in Senegal. Tensions have subsequently remained high, despite an agreement in April 1992 between the two countries to restore diplomatic relations. Few of the expatriates have returned.

Generally peaceful elections in 1993 resulted in another victory for Diouf and the PS. The French decision in 1994 to devalue the African franc by 50 percent negatively affected the Senegalese economy and sparked the most serious uprisings in the country in years, led by dissatisfied urban youths. The government quickly crushed the demonstrations and arrested hundreds. The difficult economic conditions continued, exacerbated by periodic droughts and inflation. Despite the economic problems, however, the Diouf regime retained the support of the powerful Muslim leadership in the country and won elections again in 1998, although opposition parties did make some gains, especially in the urban Dakar region. Abdoulaye Wade finally won the presidency in March 2000. By 2001 it appeared that Wade and the PDS would dominate Senegalese politics into the foreseeable future.

The greatest challenge still facing the Senegalese government was the long-standing conflict in Casamance, the southern region physically isolated from the rest of the country by The Gambia. Since 1982 a rebel group, primarily based in the Diola areas, had been fighting for independence, and there were numerous deaths. The Senegalese government refused to negotiate with the rebels. In 1998 an attempted military coup in neighbouring Guinea-Bissau, which involved guerrillas from Casamance, was repressed by Senegal and led to renewed violence in the region. A peace accord was signed in March 2001 between Senegal and Casamance.   (J.D.H./A.F.C.)

For later developments in the history of Senegal, see the BRITANNICA BOOK OF THE YEAR.

COUNTRIES OF THE GUINEA COAST

Benin

The Republic of Benin (République du Bénin) consists of a narrow wedge of territory extending northward for about 420 miles (675 kilometres) from the Gulf of Guinea in the Atlantic Ocean, on which it has a 75-mile seacoast, to the Niger River, which forms part of Benin's northern border with Niger. Benin has an area of 44,300 square miles (114,760 square kilometres) and is bordered to the northwest by Burkina Faso, to the east by Nigeria, and to the west by Togo. The official capital is Porto-Novo, but Cotonou is Benin's largest city, its chief port, and its de facto administrative capital. A French colony from the late 19th century until 1960, the country was called the Republic of Dahomey from independence until 1975 and, from 1975 until 1990, the People's Republic of Benin.

A grouping of ancient kingdoms

Prior to colonial rule, part of the territory that is now Benin consisted of powerful, independent kingdoms, including various Bariba kingdoms in the north and in the south the kingdoms of Porto-Novo and Dahomey (Danho-me, "on the belly of Dan;" Dan was a rival king on whose grave Dahomey's royal compound was built). In the late 19th century French colonizers making inroads from the coastal region into the interior borrowed the name of the defeated Dahomey kingdom for the entire territory that is now Benin; the current name derives from the Bight of Benin.   (D.Ro.)

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Benin consists of five natural regions. The coastal region is low, flat, and sandy, backed by tidal marshes and lagoons. It is composed of, in effect, a long

sandbar on which grow clumps of coconut palms; the lagoons are narrower in the western part of the country, where many have become marshes because of silting, and wider in the east, and some are interconnected. In the west the Grand-Popo Lagoon extends into neighbouring Togo, while in the east the Porto-Novo Lagoon provides a natural waterway to the port of Lagos, Nigeria, although its use is discouraged by the political boundary. Only at Grand-Popo and at Cotonou do the lagoons have outlets to the sea.

Behind the coastal region extends the *barre* country—the word being a French adaptation of the Portuguese word *barro* ("clay"). A fertile plateau, the *barre* region contains the Lama Marsh, a vast swampy area stretching from Abomey to Allada. The landscape is generally flat, although occasional hills occur, rising to about 1,300 feet (400 metres).

The *barre* country

The Benin plateaus, four in number, are to be found in the environs of Abomey, Kétou, Aplahoué (or Parahoué), and Zagnanado. The plateaus consist of clays on a crystalline base. The Abomey, Aplahoué, and Zagnanado plateaus are from 300 to 750 feet high, and the Kétou plateau is up to 500 feet in height.

The Atakora Mountains, in the northwest of the country, form a continuation of the Togo Mountains to the south. Running southwest to northeast and reaching an altitude of 2,103 feet (641 metres) at their highest point, they consist of a highly metamorphosed quartzite interior.

The Niger plains, in the northeast of Benin, slope down to the Niger River valley. They consist of clayey sandstones.

Drainage. Apart from the Niger River, which, with its tributaries the Mékrou, Alibori, and Sota, drains the

northeastern part of the country, the three principal rivers in Benin are the Mono, the Couffo, and the Ouémé. The Mono, which rises in Togo, forms the frontier between Togo and Benin near the coast. The Couffo, near which stands Abomey, flows southward from the Benin plateaus to drain into the coastal lagoons at Ahémé. The Ouémé rises in the Atakora Mountains and flows southward for 280 miles; near its mouth it divides into two branches, one draining to the east into Porto-Novo Lagoon and the other to the west into Nokoué Lake. The Atakora Mountains form a divide between the Volta and Niger basins.

Two
climatic
zones *Climate.* Two climatic zones may be distinguished— a southern and a northern. The southern zone has an equatorial type of climate with four seasons—two wet and two dry. The principal rainy season occurs between mid-March and mid-July; the shorter dry season lasts to mid-September; the shorter rainy season lasts to mid-November; and the principal dry season lasts until the rains begin again in March. The amount of rain increases toward the east. Grand-Popo receives only about 32 inches (800 millimetres) a year, whereas Cotonou and Porto-Novo both receive approximately 50 inches. Temperatures are fairly constant, varying between about 72° and 93° F (22° and 34° C), and the relative humidity is often uncomfortably high.

In the northern climatic zone, there are only two seasons, one dry and one rainy. The rainy season lasts from May to September, with most of the rainfall occurring in August. Rainfall amounts to about 53 inches a year in the Atakora Mountains and in central Benin; farther north it diminishes to about 38 inches. In the dry season the harmattan, a hot, dry wind, blows from the northeast from December to March. Temperatures average about 80° F (27° C), but the temperature range varies considerably from day to night. In March, the hottest month, diurnal temperatures may rise to 110° F (43° C).

Plant and animal life. The original rain forest, which covered most of the southern part of the country, has now largely been cleared, except near the rivers. In its place, many oil palms and rônier palms have been planted and food crops are cultivated. North of Abomey the vegetation is an intermixture of forest and savanna (grassy parkland), giving way farther north to savanna. Apart from the oil and rônier palms, trees include coconut palms, kapok, mahogany, and ebony.

In the extreme north is the "W" National Park (1,938 square miles), which extends into Burkina Faso and Niger. Its varied animal life includes elephants, leopards, lions, antelope, monkeys, wild pigs, crocodiles, and buffalo. There are many species of snakes, including pythons and puff adders. Birds include guinea fowl, wild duck, and partridge, as well as many tropical species. The Pendjari National Park (1,062 square miles) borders on Burkina Faso.

Settlement patterns. The southern provinces make up one-fourth of the total area but are inhabited by more than two-thirds of the total population. Many of these people are clustered near the port of Cotonou, which is the focus of the commercial and political life of the country, and Porto-Novo, the official capital. The cultivation of subsistence crops, such as corn (maize), cassava, and yams, is intensive on the outskirts of the towns. The *barre* region and the Benin plateaus are planted with oil palms, which form the cash crop, as well as with subsistence crops. To the north, the aspect of the countryside changes as savanna vegetation increases and the population diminishes; some areas are uninhabited, except by Fulani nomads. Villages, instead of being encountered frequently as in the south, become scattered. Parakou is an important northern market town, dating from colonial times.

Benin's
towns The towns exhibit traditional African, colonial European, and modern influences. Traditional African (or precolonial) mud houses, markets, shrines, and statues are found in small towns as well as in Abomey, Porto-Novo, and, to a lesser degree, Cotonou, and the Somba region in the northwest has traditional thatched-roof, turreted houses. Colonial European styles dominate in most towns, especially in Cotonou. Colonial buildings, some dating from the 18th century, include train stations, official buildings,

and private homes, as well as such structures as the former Portuguese fort at Ouidah that was used in the slave trade. Modern architecture is found in private homes, port facilities, and hotels. (S.S.A./D.Ro.)

The people. Despite attempts at greater national unity and integration since 1960, differences among Benin's ethnic groups survive to a marked degree.

The Fon, who make up nearly 40 percent of the population, live in various parts of the country and especially in Cotonou. The Yoruba, who are related to the Nigerian Yoruba, live mainly in southeastern Benin and constitute about one-eighth of Benin's population. In the vicinity of Porto-Novo the Goun (Gun) and the Yoruba (known in Pobé and Kétou as Nago, or Nagot) are so intermixed as to be hardly distinguishable. Among other southern groups are various Adja peoples, including the Aizo, the Holi, and the Mina.

The Bariba, the fourth-largest ethnic group, comprise several subgroups and make up about one-twelfth of Benin's population. They inhabit the northeast, especially towns such as Nikki and Kandi that were once Bariba kingdoms. The Somba (Ditamari) are found in Natitingou and in villages in the northwest. Other northern groups include the Dendi, the Djougou, the Pila (Pilapila), and the nomadic Fulani (Peul). Several thousand French, Lebanese, and other nationals reside in Benin, primarily in Cotonou and Porto-Novo.

French is the official language and the language of instruction, but each ethnic group has its own language, which the educated also speak. Most adults living in the various ethnic communities also speak the dominant language of each region. The most widely spoken languages are Fon, Ge (Mina), Bariba, Yoruba, and Dendi.

Religious groups. Although Christian missions have been active in the coastal region since the 16th century, only one-fifth of the total population is Christian; of the Christians, about four-fifths are Roman Catholic. Islām has adherents in the north and southeast; about one-sixth of the total population is Muslim. Most of the population Traditional
religions adheres to traditional religions. In the south, animist religions, which include fetishes (objects regarded with awe as the embodiment of a powerful spirit) for which Benin is renowned, retain their traditional strength.

Demographic trends. Benin's rate of population growth is high for western Africa, resulting primarily from a birth rate that is higher than the regional average and a death rate that is lower. Moreover, nearly one-half of the population is less than 15 years of age, assuring the country's continued high growth rate. Life expectancy for males is about 49 years and for females about 52 years. Only about one-fifth of the population is urban, concentrated mostly in Cotonou, the only city with a population of more than 400,000. (D.Ro.)

The economy. Since independence, Benin's regular and developmental budgets have been dependent on external support, primarily from France and international organizations. This support has rendered a little less painful the formidable economic stagnation and low standard of living of the overwhelming majority of the population.

The regime that came to power in a 1972 coup attempted from 1975 to restructure the economy more or less along socialist principles and to disengage from dependence on France. Most sectors of the economy were nationalized or otherwise turned over to government control, and economic relations were established with the Soviet Union and other socialist countries, as well as with Benin's neighbours. By the early 1980s it was clear that—though the economy was restructured and, at least on paper, more efficient and diversified and France's contribution to Benin's economy diminished—corruption persisted and that the overall economic situation had not improved. "Liberalization" of the economy in the mid-1980s also failed to produce positive results. Accompanying changes in the constitution and regime in the early 1990s, the remnants and slogans of Marxism were wiped out, and privatization of the economy began.

Resources. The few stretches of tropical forest that remain in Benin, mostly in the southwest and central areas, contain mahogany, iroko, teak, samba, and other tropi-

cal hardwoods. The rivers and lagoons are rich in fish. Mineral deposits include iron ore both in the Atakora Mountains and northeast of Kandi, limestone deposits at Onigbolo, chromium ore and a little gold in the northwest near Natitingou, marble at Dadjo, an important deposit of pottery clay at Sakété, and ilmenite (a mineral source of titanium) near the coast. Offshore oil was discovered in 1968 in the Sémé field near Cotonou and has been exploited since 1982.

Agriculture and fishing. About 70 percent of the working population depends on agriculture. Since the mid-1980s Benin has produced yams, cassava, corn (maize), millet, beans, and rice to achieve self-sufficiency in staple foods. Among cash crops, the formerly predominant palm product output declined considerably in the 1980s, but cotton output rose. The output of karité, peanuts (groundnuts), cacao beans, and coffee also has increased. Livestock include cattle, sheep and goats, pigs, horses, and poultry. Substantial quantities of fish are caught annually in the lagoons and rivers, while coastal fishing produces a smaller, but growing, amount. Most of the fish is exported to Nigeria or Togo. Shrimp and deep-sea fishing are developing, using modern vessels.

Industry. Manufacturing plants and secondary industries include several palm-oil-processing plants in Ahozon, Avrankou, Bohicon, Cotonou, Gbada, and Pobé; cement plants at Onigbolo and Pobé; several cotton-ginning facilities in the north; a textile mill at Parakou; a sugar refining complex at Savé; a soft-drink plant; a brewery; and two shrimp-processing plants.

Electricity is generated thermally by plants located at Bohicon, Parakou, Cotonou, and Porto-Novo. About half of Benin's demand for electricity is met by importing power from Ghana's Volta River Project at Akosombo. In 1988 operations commenced at the hydroelectric installation of the Mono River Dam, a joint venture between Benin and Togo on their common southern boundary.

Finance. Liquidation of Benin's three state-owned banks took place in the late 1980s and early 1990s as part of economic privatization, and four private banks opened, including the Bank of Africa-Benin. Citizens of Benin began to transfer their savings from foreign banks. With the advent of privatization, foreign aid and assistance grew, particularly funding for developmental projects from the United States and the Commission of the European Community, the latter of which also agreed to help pay the wages of civil servants. France continues to provide financial assistance. The currency of Benin is the CFA (Communauté Financière Africaine), which is fully guaranteed by and pegged to the French franc.

Trade. Benin's export earnings rely on agricultural products, such as cotton, palm oil, cocoa, and coffee, exported to such countries as Portugal, Italy, France, Thailand, Taiwan, and the United States. Informal trade (smuggling) across the border with Nigeria has also affected Benin's negative trade balance. One of Benin's main, albeit underexploited, trade assets is the deepwater port at Cotonou, which serves as a sea outlet for the Republic of Niger and as a secondary port for Nigeria and thus holds a potential to earn lucrative customs duties. Benin has traditionally imported various manufactured products, machinery, chemicals, beverages, and tobacco, as well as cereals.

Transportation. There are two paved, mostly two-lane, road networks. One runs parallel to the coast of the Gulf of Guinea from the Togolese border, through Cotonou and near Porto-Novo, to the Nigerian border. The other road runs north from Cotonou, near Abomey and Dassa, to Parakou in the north. Roads from Parakou to Niger's border and from near Abomey to Burkina Faso's border are unpaved and are barely passable in the rainy season.

There is a railroad from Cotonou to Parakou. Another railroad, parallel to the coast, does not extend to either the Togolese or the Nigerian border.

Interconnected coastal lagoons are navigable by small craft known as pirogues. The Ouémé, Couffo, and Mono rivers are navigable by small boats for several dozen miles. The country's only port is at Cotonou. An international airport in Cotonou links Benin with other countries of Africa and with Europe. There is also limited domestic airline service. (S.S.A./D.Ro.)

Administration and social conditions. Benin has experienced much political instability and unrest. It suffered through 12 years of unstable government, including several coups d'état, beginning three years after independence. The regime of President Mathieu Kérékou, who came to power in a 1972 coup, enjoyed almost two decades of fragile but unprecedented stability. The Marxist rhetoric introduced in 1974 culminated in repressive military rule in the late 1970s, but this had largely ceased by the early 1980s. During this period, however, the Benin People's Revolutionary Party (PRPB) was the only legal political party. A National Revolutionary Assembly, elected by citizens, chose the president, who was also head of state.

Benin was the first African country to make a post-Cold War transition away from Marxism-Leninism. Kérékou himself abandoned in December 1989 the Marxist-Leninist ideology that he had promulgated in the mid-1970s. In December 1990 a new constitution was approved, guaranteeing human rights, freedom to organize political parties, the right to private property, and universal franchise. While multiparty elections, a National Assembly, and a presidency were provided for, the country's poor economy and history of fractured political alliances lent an element of uncertainty to the political future. Benin has a transitional constitutional court, a high court of justice, and a supreme court.

Education. The public education system has followed the French pattern since colonial times. A six-year primary school cycle (for children ages 6–11) is followed by six years of secondary education (ages 12–17). In the mid-1970s major reforms were introduced both to conform to the then-prevalent Marxist-Leninist ideology and to shed French influence. The reforms failed as teachers, parents, and university-bound students objected to the lowering of standards, and the reforms were largely abandoned by the late 1980s. School enrollment levels for boys in the late 1980s were at least double those for girls. In the early 1990s the National University of Benin, founded in 1970, enrolled approximately 9,000 students. The university's student body has been, along with workers, the main political force in the country since the early 1980s.

Health and welfare. Benin has a national health-care system that maintains hospitals in Cotonou, Porto-Novo, Parakou, Abomey, Ouidah, and Natitingou, in addition to medical dispensaries, maternity centres, and other small, specialized health-care facilities in these and smaller towns. Financial aid from international organizations provides resources to compensate for a shortage of medical personnel and medications. Malaria, guinea worm, and river blindness are widespread.

Cultural life. French colonial rule and subsequent close ties with France have left a deep impact on all aspects of cultural life, especially among the educated segments of the population and in the southern cities. Each ethnic group also has its own centuries-old tradition, which itself often mixes with the French influence. These cultural traditions are clustered in two distinct regions, the largely Muslim north and the largely animist and Christian south.

In Cotonou one finds many kinds of commercial enterprises, often with a French flavour, such as restaurants, cafés, and discotheques. Diplomats of foreign governments and many of Benin's elite live in newer residential sections. There are several movie theatres and several hotels that provide entertainment. Most other towns have modern sections on a smaller scale.

In other sections of the towns, however, tradition dominates cultural life. Extended families live in family compounds in distinct neighbourhoods, where they practice religious rites and celebrate festivals with music and dance. Markets where foodstuffs, clothing, and traditional medicines and arts are sold are important centres of daily life.

The arts. Artistic traditions in Benin are very old and are represented in practically every village. Plastic art is the most prominent, as carved wooden masks representing images and spirits of the departed are made and used in traditional ceremonies. Other artistic items are bronze

Marginal notes:
Agricultural production

Diversity of cultural traditions

statuettes, pottery, appliquéd tapestries recounting the history of kings of precolonial Dahomey, and fire engraving on wooden bowls, which often have religious meaning. Probably the best-known art objects are the Yoruba wooden masks called *guelede* from the region of Porto-Novo. Street musicians are found in various neighbourhoods, and modern dance ensembles perform at clubs.

Cultural institutions. An artisan village is attached to the Historical Museum of Abomey (formerly the Royal Palace). There is an excellent ethnographic museum in Porto-Novo, a historical museum in Ouidah, and the Open-Air Museum of Ethnography and Natural Sciences in Parakou. The National Library is in Porto-Novo. Art galleries are the Cultural and Artistic Centre and the French Cultural Centre, both in Cotonou, and the CAZAM in Porto-Novo. Cultural centres sponsored by the French and American governments maintain libraries and organize lectures, concerts, and other cultural activities.

Recreation. The national sport played by several teams is football (soccer). There is a modern sport stadium in Cotonou.

Press and broadcasting. Radio programs are broadcast from Cotonou in French, English, and a number of local languages. There is also a limited television service. A daily newspaper, *La Nation,* is published in Cotonou and is controlled by the government; there are also two other dailies and several weekly or biweekly publications. Newspapers published in Senegal and Côte d'Ivoire (in French) and newspapers and magazines from elsewhere may be found in bookstores and newsstands.

For statistical data on the land and people of Benin, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.   (D.Ro.)

HISTORY

As a political unit, Benin was created by the French colonial conquest at the end of the 19th century. In the precolonial period, the territory comprised a multiplicity of independent states, differing in language and culture. The south was occupied mainly by Ewe-speaking peoples, who traced their traditional origins to the town of Tado (in modern Togo). During the 16th and 17th centuries, the most powerful state in this area was the kingdom of Allada (Ardra), but in the 18th and 19th centuries its place was taken by Dahomey. In the north, the largest group was the Bariba, the most important state being the kingdom of Nikki, which formed part of a confederacy including other Bariba states located in what is today Nigeria. The Somba, in the northwest, did not form a kingdom.

The slave trade. The Portuguese first explored the coast of Benin in 1472 but did not begin trading there un-

Beginning of European trade til 1553. During the 17th century the Dutch, English, French, and other Europeans also entered the trade. The principal export before the mid-19th century was always slaves. The volume of slave exports was at first small, but it increased rapidly in the second half of the 17th century, when this area became known to Europeans as the "Slave Coast," and remained high until the 1840s. The principal centre for the trade was the coastal kingdom of Ouidah (Whydah), which was originally a tributary of Allada but which had become an independent state by the 1680s. The slaves exported were predominantly war captives and were drawn from the entire area of modern Benin, including northern peoples such as the Bariba as well as communities near the coast. The Atlantic slave trade had a substantial and deleterious impact in Benin, causing the depopulation of certain areas as well as a general militarization of society. The prominence of slaves from this area in the transatlantic trade is reflected in the survival of elements of its culture in black communities of the New World, especially in the "voodoo" religion of Haiti, which incorporates many spirit cults and deities of the Ewe-speaking peoples.

The kingdom of Dahomey. Dahomey (also called Abomey, after its capital city) was the state of the Fon people. It was originally a dependency of Allada, but during the 17th century a ruler called Wegbaja declared himself king and made Dahomey an independent state. Under King Agaja (reigned 1708?–40) Dahomey overran

the coastal area, conquering Allada in 1724 and the commercial centre of Ouidah in 1727, thus establishing itself as the dominant power in the area. A section of the royal family of Allada, however, founded the new kingdom of Porto-Novo, on the coast to the east, which successfully resisted Dahomean authority and competed with Ouidah for control of the Atlantic trade. Dahomey itself was attacked and defeated by the kingdom of Oyo, to the northeast (in modern Nigeria), to which it was obliged to pay tribute from 1730 onward. Dahomey attained the height of its power under the kings Gezo (1818–58) and Glélé (1858–89). Gezo liberated Dahomey from its subjection to Oyo by defeating the latter in 1823. Dahomean attempts at expansion eastward, however, brought it up against the powerful state of Abeokuta (also in Nigeria). Dahomean attacks upon Abeokuta in 1851 and 1864 were decisively defeated.

Dahomey was a despotic and militaristic kingdom. Its power was based upon a highly trained standing army, which included a female contingent (called the "Amazons" by Europeans) drawn from the king's wives. The king's authority was buttressed by an elaborate cult of the deceased kings of the dynasty, who were honoured by the offering of human sacrifices at yearly public ceremonies (the "annual customs"). Its rulers succeeded in uniting the disparate communities which they absorbed into a new national identity, so that the conquered subjects of Dahomey came to regard themselves as Fon. During the 18th and early 19th centuries, Dahomey was a major supplier of slaves for the transatlantic trade, but by the mid-19th century the volume of the slave trade was in decline. In 1852 King Gezo was forced by a British naval blockade to accept a treaty abolishing the slave trade, although this was evaded in practice. From the 1840s onward Gezo promoted the export of palm oil, produced by slave labour on royal plantations, as a substitute for the declining slave trade.

The French conquest and colonial rule. During the 17th century several of the European nations engaged in the Atlantic slave trade maintained trading factories in the Dahomey area, and during the 18th century the English, French, and Portuguese all possessed fortified posts in Ouidah. The French first established a factory in Allada in 1670 but moved from there to Ouidah in 1671. Although this factory was abandoned in the 1690s, the French built a fort (known as Fort Saint Louis) in Ouidah in 1704. The European forts in Ouidah were, however, all abandoned about the end of the 18th century, the French establishment being withdrawn in 1797.

In 1842 the French fort at Ouidah was reoccupied as a base for the new trade in palm oil, and in 1851 the French government negotiated a commercial treaty with King Gezo of Dahomey. Subsequently fears of preemption by British colonial expansion led to the extension of formal French rule in the area. A protectorate was briefly established over the kingdom of Porto-Novo in 1863–65 and was definitively reestablished in 1882. Treaties purporting to secure cession of the port of Cotonou, between Ouidah and Porto-Novo, were also negotiated with the Dahomean authorities in 1868 and 1878, though Cotonou was not actually occupied until 1890. King Behanzin, who had succeeded to the Dahomean throne in 1889, resisted the French claim to Cotonou, provoking the French invasion and conquest of Dahomey in 1892–94. Behanzin was then deposed and exiled, and the kingdom of Dahomey became a French protectorate.

French ambitions to extend their control into the interior, north of Dahomey, were threatened by the rival expansionism of the British, who were established in what was to become their colony of Nigeria to the east, and in 1894 both the British and French negotiated treaties of protection with the kingdom of Nikki. The Anglo-French convention of 1898, however, settled the boundary between the French and British spheres, conceding Nikki to the former. The boundary with the German colony of Togo to the west was settled by the Franco-German conventions of 1885 and 1899. The present frontiers of Settlement of boundaries Benin were established in 1909, when the boundaries with the neighbouring French colonies of Upper Volta and Niger were delimited. The colony was at first called Benin

(from the Bight of Benin, not the precolonial kingdom of Benin, which is in Nigeria), but in 1894 it was renamed Dahomey, after the recently incorporated kingdom. From 1904 Dahomey formed part of the federation of French West Africa, under the governor-general in Senegal. Descendants of Portuguese settlers, freed slaves returning from Portuguese colonies in the Americas (called Brésiliens, or Brazilians), and missionaries were instrumental in spreading Christianity and Western education in the south but not in the Muslim north; by the 1950s Dahomey was known as the "Latin Quarter" of French West Africa.

Decolonization and independence. In 1946 Dahomey became an overseas territory of France. It was created an autonomous republic within the French Community in 1959 and achieved complete independence on Aug. 1, 1960. During the period of decolonization, the nationalist movement in Dahomey became fragmented, with the emergence of three regionally based political parties—led by Sourou-Migan Apithy (president in 1964–65), Justin Ahomadégbé (1972), and Hubert Maga (1960–63 and 1970–72), drawing their principal support respectively from Porto-Novo, Abomey, and the north. After independence in 1960, these political problems were exacerbated by economic difficulties, reflected in student and trade union unrest. The ensuing instability resulted in six successful military coups d'état between 1963 and 1972 and periods of army rule in 1965–68 and 1969–70. In a last military coup, on Oct. 26, 1972, power was seized by Major (later General) Mathieu Kérékou. The country pursued a Marxist-Leninist ideology, and Kérékou renamed the country the Republic of Benin. In 1989 Kérékou cut the Marxist-Leninist ties and headed in the direction of greater democratization. Kérékou was defeated in multiparty presidential elections in 1991, but he returned to the presidency in 1996 and 2001.

Into the 21st century, the government attempted to advance the private sector, although economic unrest continued over unresolved issues such as corruption. Economically, Benin continued to be dependent on Nigeria, and internationally it attempted to defuse the accusation that it allowed children to be sold into slavery.

For later developments in the history of Benin, see the BRITANNICA BOOK OF THE YEAR.　　　　　(R.La./D.Ro.)

Cameroon

The Republic of Cameroon (République du Cameroun) is a triangle-shaped state wedged between western and central Africa. It covers an area of 179,714 square miles (465,458 square kilometres) and is bordered by Nigeria to the northwest, Chad to the northeast, the Central African Republic to the east, Congo to the southeast, Gabon and Equatorial Guinea to the south, and the Atlantic Ocean to the southwest. Its ethnically diverse population is among the most urban in western Africa. The capital is Yaoundé.

The country's name is derived from Rio dos Camarões (River of Prawns)—the name given to the Wouri River estuary by Portuguese explorers of the 15th and 16th centuries. Camarões was also used to designate the river's neighbouring mountains. Until the late 19th century, English usage confined the term the Cameroons to the mountains, and the estuary was called the Cameroons River or, locally, the Bay. In 1884 the Germans extended the word Kamerun to their entire protectorate, which largely corresponded to the present state.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Cameroon can be divided into the southern, western, central, and northern geographic regions. The southern region extends from the Sanaga River to the southern border and from the coast eastward to the Central African Republic and Congo. It consists of coastal plains that are about 25 miles (40 kilometres) wide and a densely forested plateau with an average elevation of a little more than 2,000 feet (600 metres).

The western region extends north and west from the Sanaga River and continues north along the Nigerian border as far as the Bénoué (Benue) River. The relief is mostly mountainous, the result of a volcanic rift that extends

Upland areas [margin]

northward from the island of Bioko (Fernando Po). Near the coast, the active volcanic Mount Cameroon rises to the highest elevation in western Africa—13,435 feet (4,095 metres).

The central region extends east from the western highlands and from the Sanaga River north to the Bénoué River. The land rises progressively to the north and includes the Adamawa (Adamaoua) Plateau, with elevations between 2,450 and 4,450 feet.

North of the Bénoué River, the savanna plain declines in elevation as it approaches the Lake Chad basin. The region contains scattered inselbergs, or mounds of erosion-resistant rock rising above the plains. The Gotel Mountains of the Adamawa trend from south to north, culminating in the Mandara Mountains of the northwest.

Drainage. The rivers of Cameroon form four large drainage systems. In the south, the Sanaga, Wouri, Nyong, and Ntem rivers drain into the Atlantic Ocean. The Bénoué River and its tributary, the Kébi, flow into the Niger River basin of Nigeria. The Logone and Chari rivers—which form part of the eastern border with Chad—drain into Lake Chad, whereas the Ngoko River joins the Sangha River and flows into the Congo (Zaire) River basin.

Climate. Lying wholly within the tropics, the country is hot throughout the year; mean annual temperatures range between 70° and 82° F (21° and 28° C), although they are lower in areas of high elevation.

The incidence of rainfall depends largely on the seasonal movements of two contrasting air masses: a dry continental tropical air mass, which originates over the Sahara, is associated with hot, dusty weather, whereas a warm and humid maritime tropical air mass, originating over the Atlantic, brings rain-bearing winds. Rainfall decreases from south to north. Along the coast, the rainy season lasts from April to November, and the relatively dry season lasts from December to March; a transition period from March to April is marked by violent winds. The mean annual rainfall of more than 100 inches (2,500 millimetres) occurs in about 150 days.

In the central plateau region, rainfall decreases to 60 inches. There are four seasons—a light rainy season from May to June, a short dry season from July to October, a heavy rainy season from October to November, and a long dry season from December to May. The north, however, has a dry season only from October to May and an average annual rainfall of about 30 inches. The wettest part of the country lies in the western highlands. Debundscha Point on Mount Cameroon has a mean annual rainfall of more than 400 inches—an average attained by only two other locations in the world—most of which falls from May to October.

Plant and animal life. The hot and humid south supports dense rain forests in which hardwood evergreen trees—including mahogany, ebony, obeche, dibetu, and sapelli—may grow to more than 200 feet. There are large numbers of orchids and ferns.

Plants of the tropical rain forest [margin]

Mangroves grow along the coasts and the mouths of rivers. The rain forest gives way to the semi-deciduous forest of the central region, where a number of tree species shed their leaves during the dry season. North of the semi-deciduous forest, the vegetation is composed of wooded savanna with scattered trees 10 to 60 feet high. The density of trees decreases toward the Chad basin, where they are sparse and mainly of *Acacia* species.

Between 4,000 and 8,000 feet, the tropical rain forest differs from that of the lowlands; the trees are smaller, are of different species, and are festooned with mosses, lichens, and other epiphytes. Above the forest zone are drier woodland, tall grassland, or patches of mountain bamboo. Above about 7,800 feet in the interior and above about 10,000 feet on Mount Cameroon, short grasses predominate.

The country's dense forests are inhabited by screaming red and green monkeys, chimpanzees, and mandrills, as well as rodents, bats, and numerous birds—from tiny sunbirds to giant hawks and eagles. A few elephants survive in the forest and in the grassy woodlands, where baboons and several types of antelope are the most common animals. The Waza National Park in the north, which was origi-

nally created for the protection of giraffes and antelope, abounds in both forest and savanna animals, including monkeys, baboons, lions, leopards, and birds that range from white and gray pelicans to spotted waders.

Settlement patterns. In general there is a cultural division between the north and the south. The northern savanna plateau is inhabited by Sudanic and Arab pastoralists who migrate seasonally in search of grazing land, whereas the forested and hilly south is peopled by Bantu agriculturists in permanent villages. The north is predominantly Muslim, whereas the southern peoples adhere to animism and Christianity.

Population density is greatest in the western highlands, in the southern forest, and along parts of the coast; it is lowest in the southeast interior. Douala is the largest city and the country's main port. Yaoundé is an important transportation and communication centre. Garoua is a port on the Bénoué River. Other towns of importance include Nkongsamba, Bafoussam, Bamenda, Maroua, and Kumba. In most cases, the provincial capitals are the largest towns and have the greatest potential for expansion.

The principal linguistic and ethnic groups

The people. The country has been described as a "racial crossroads" because of its more than 200 different ethnic groups. There are three main linguistic groups: the Bantu-speaking people of the south, the Sudanic-speaking people of the north, and those who speak the Semi-Bantu languages of the west.

The Bantu settled in the Cameroons from equatorial Africa. The first group that invaded the country included the Maka, Ndjem, and Duala. They were followed at the beginning of the 19th century by the Fang (Pangwe) and Beti peoples.

The Sudanic-speaking peoples include the Sao, who live on the Adamawa Plateau; the Fulani; and the Kanuri. The Fulani came from the Niger basin in two waves, in the 11th and 19th centuries; they were Muslims who converted and subjugated the peoples of the Logone valley and the Kébi and Faro river valleys. The third ethnic group consists mainly of small tribes, except for the Bantu-related Bamileke, who live between the lower slopes of the Adamawa Plateau and Mount Cameroon. Other western Semi-Bantu-speaking tribes include the Tikar, who live in the Bamenda region and in the western high plateau.

The oldest inhabitants of the country are the Pygmies, locally known as the Baguielli and Babinga, who live in the southern forests. They have been hunters and gatherers for thousands of years and live in small hunting bands.

European missions and colonization led to the introduction of European languages. During the colonial era German was the official language; it was later replaced by English and French, which have retained their official status.

About one-quarter of the population continue to adhere

Buffon's kob, a type of antelope, at a watering hole in Waza National Park, Cameroon.

to traditional religious beliefs. More than two-fifths of the population are Christian, mainly Roman Catholic. Muslims comprise one-fifth of the population.

Cameroon's population is growing at about the same high rate as sub-Saharan Africa as a whole. The birth and death rates, however, are both somewhat lower than average. Nearly half the population are below age 15, and more than two-fifths, a comparatively high proportion, live in urban areas. Life expectancy, at 51 years, has improved greatly in the late 20th century.

The economy. Until the late 20th century the economy of Cameroon was basically agricultural; it has since experienced a shift toward a mining economy.

Cameroon's main problem, in common with the other developing countries of Africa, is the acquisition of capital to finance resource development. When foreign investment capital is scarce, the country depends largely on the sale of its products on the world market. Fluctuations in world prices of raw materials such as cocoa and coffee, however, make the future unpredictable.

The government sets guidelines in its five-year plans and attracts private capital for the development of certain sectors of the economy. The first two plans (1961–65 and 1966–71) concentrated on expansion of educational facilities, diversification of farm production, and selective industrialization and on rural development and the introduction of rural cooperatives, respectively. Subsequent plans have extended these, relying on increasingly greater proportions of private investment.

Foreign indebtedness rose along with development spending, though the government was successful in keeping its debt service within reasonable levels. In the late 1980s, however, budget deficits compelled Cameroon to resort to external borrowing and to accept the intervention of the International Monetary Fund's structural readjustment programs.

There are four different company tax systems, which offer various benefits to developing industries. Most tax revenues are obtained from petroleum royalties, corporation profit levies, property taxes, and import and export duties.

Worker-employer relations have been peaceful since 1960, which may, in part, result from government appointment of top union officials and the illegality of strikes. Employers' associations include Chambers of Commerce in Douala and Yaoundé and associations for those engaged in industry and the import-export trade. The two main trade unions are the National Union of Private Journalists and the Organization des Syndicats des Travailleurs Cameroonais, both based in Yaoundé.

Agriculture, forestry, and fishing. The growth of the petroleum industry since 1980 has resulted in a gradual decline in the importance of agriculture, forestry, and fishing to the gross domestic product. About three-fourths of the working population are engaged in this sector, compared with 90 percent in the 1970s. Primary agricultural and forest products provide about one-third of total export earnings, with cocoa and coffee the leading agricultural exports. Small family holdings are responsible for about 80 percent of the agricultural exports, with less than 10 percent coming from commercial plantations. The main subsistence crops include plantain, beans, potatoes, yams, cassava, corn (maize), and oil palm in the south and peanuts (groundnuts), millet, and cassava in the north.

Cocoa is grown mainly in the south. The country ranks as the world's fifth largest producer. Robusta coffee, which accounts for about 85 percent of the coffee crop, is grown both in the southern warm and humid parts of the country and in the western high plateau, where arabica coffee is also grown. Yields have been adversely affected by the increasing age of the plantations and delay in modernizing.

Coffee and cocoa production

Cotton was introduced in 1952; it is grown largely in the grasslands by private farmers. Systematic diversification of agricultural production into such crops as palm oil, rubber, and sugar has taken place.

Food production has kept pace with population growth, and the country is generally self-sufficient. Domestic consumption of meat is reasonably high. Livestock is exported to Nigeria, Equatorial Guinea, and the Congo, and hides and skins to Nigeria and Equatorial Guinea. Commercial

fishing constitutes about one-third of the total marine catch, while traditional coastal fishing makes up the remainder. The freshwater catch is about one-third the size of the marine catch.

About one-half of the country is forested, but only about one-third of the available hardwood forest resources are exploited. Forestry is limited to the most accessible areas along the Douala–Yaoundé railway and the main roads.

Industry. Cameroon is endowed with abundant mineral wealth, but until recently there was no indication of any meaningful exploitation. Large amounts of kyanite (an aluminum silicate) and bauxite are deposited at Minim-Martap and Ngaoundéré on the Adamawa Plateau. Bauxite deposits at Minim-Martap remain unexploited because of weak world demand and the heavy investment involved in both mining and building the necessary transportation infrastructure. Limestone deposited near Garoua is quarried for use in cement plants. There is some gold in East Cameroon, and cassiterite occurs in the Darlé River valley in the northeast. Unexploited resources include iron ore (found at Kribi) and uranium.

In 1976 oil was found offshore at Rio-del-Ray. Production began in 1977, and since 1980 oil has been the country's most important export. Despite the fall in world oil prices, petroleum remains attractive as the main source of income. Natural gas deposits also have been located but remain unexploited because of the high investment costs.

The contribution of manufacturing to the economy has grown strongly in the late 20th century. Production is centred on import substitution (*e.g.,* soap, tires, and footwear) and the processing of agricultural commodities (sugar refining, cotton spinning, tobacco and wood-pulp production). The industrial sector consists of one major heavy industrial complex, the Edéa aluminum smelter, which smelts imported bauxite.

The government is the major participant in the industrial sector, mainly through the Société National d'Investissement, which emphasizes reducing dependence on imported materials and establishing small and medium-sized enterprises. Plants have been set up to produce tires, cement, and fertilizer, to refine petroleum, and to tan hides from locally produced livestock.

The main source of hydroelectric power is the Sanaga River; the chief installations are at Edéa, on the Sanaga Falls, and at Song-Loulou. The station at Lagdo on the Bénoué River was financed and built with aid from China.

Finance and trade. Cameroon is linked together with several other countries in western Africa in a monetary union with a common currency, the CFA (Communauté Financière Africaine, or African Financial Community) franc. The CFA franc is convertible into any currency, but France must approve direct investment by citizens within the franc zone in countries outside of it, the issue and sale of foreign stocks and shares in the area, and borrowings from outside the area. France is represented on the board of directors of the Central Bank in Yaoundé; its notes and coins also are legal tender. Cameroon has its own monetary committee, on which France is represented, and a National Credit Council.

There are a number of foreign commercial banks operated by Cameroonian, French, British, and American interests. In addition to these, there are several development banks. Most insurance companies are French-owned.

Most trade is carried out with the EEC countries. France is the largest individual trading partner; it supplies more than one-third of Cameroon's imports and takes almost one-fourth of its exports. Trade outside the Common Market is primarily with the United States and Japan. Trade with other African and Arab countries has increased considerably.

Major exports include crude oil, cocoa, coffee, cotton, and timber. Others include oil-palm products, tea, rubber, peanuts, bananas, and fresh vegetables, as well as factory products such as aluminum, textiles, plastics, beverages, and confectionery. Major imports are machinery and transportation equipment and spare parts, fertilizers, pesticides, electronics, clothing, and textiles.

Transportation. The difficult terrain and heavy rainfall in the south have been contributory factors to the absence

Monetary relations with France

of an adequate transportation network. The north has traditionally been isolated from the south. Transportation is more developed in some regions than in others; the best roads are in the coastal region, whereas the roads in eastern Cameroon and on the western high plateau are few and are often in bad condition.

A major project was the completion of the first all-weather highway from Yaoundé to the commercial centre at Douala and between Yaoundé and the western high plateau. Another road-building program was completed in the Bertoua region in the southeast in 1986. The World Bank has provided financial support for programs of road maintenance.

The rail system nearly doubled in track length between 1965 and 1985, with the extension of the main line from Yaoundé to Ngaoundéré in the first and second phases of the Trans-Cameroon Railway and the extension of the short branch of the western line to Kumba. The rail line from Douala to Yaoundé was shortened and realigned in a modernization program.

The main port is Douala, on the estuary of the Wouri River, which accounts for 95 percent of Cameroonian port traffic. One of the best-equipped ports in western Africa, it has docks for cargo ships, including a wood-loading dock and a tanker dock with adjacent facilities for the unloading and storage of minerals. The first phase of a major port extension scheme (to increase annual capacity to seven million tons) was completed in 1980, and work began in 1983 on a rehabilitation scheme that included construction of container facilities.

The port of Douala

Douala handles most of the goods that are traded by Chad and the Central African Republic; the river networks leading to it serve as the main arteries of transit to these countries. The minor ports include Kribi at the mouth of the Kienké River, which is used primarily for the shipment of logs and cocoa from the interior; the ocean port of Limbe in western Cameroon, which handles only a modest amount of traffic; and Tiko, on a creek leading to the Wouri estuary, which handles bananas, wood, and rubber. In the north, the river port of Garoua, on the banks of the Bénoué, transports goods to Nigeria; the upper Bénoué, however, is navigable only from 7 to 10 weeks each year.

Douala is the main international airport, and Yaoundé and Garoua also handle international flights. There are domestic airports at Tiko, Ngaoundéré, Bafoussam, Bamenda, Maroua, Ebolowa, Bertona, and Batouri, as well as numerous airfields. Cameroon Airlines, which is jointly owned by the government and by Air France, provides domestic service and routes to European and African cities.

Administration and social conditions. *Government.* By the constitution of 1961, the states of West Cameroon and East Cameroon were linked together into a federation. The constitution of 1972, subsequently revised, replaced the federation with a centralized government, the United Republic of Cameroon. Executive powers are conferred on the president, who is the head of the government and chief of the armed forces and appoints all ministers. The president is elected for a period of five years by direct and secret universal suffrage. A constitutional reform in 1984 changed the name of the country to the Republic of Cameroon.

The federation of the two states

Legislative power is held by a unicameral National Assembly. It has 180 members, directly elected for five-year terms. The National Assembly shares with the president the initiative for proposing legislation, which it adopts on a simple-majority basis.

The republic is divided into 10 provinces, each administered by a governor. Each province is further divided into departments.

Cameroon was a de facto one-party state from 1966 and was dominated by the Cameroon National Union (UNC), a merger of six political parties; it was renamed the Cameroon People's Democratic Movement in 1985. After much political unrest and many violent clashes, a constitutional amendment in 1990 established a multiparty system. Other constitutional reforms in 1993 sought to decentralize the government. The main opposition is the Social Democratic Front.

A Higher Judicial Council, which along with the presi-

dent is responsible for guaranteeing the independence of the judiciary, advises the president on the nomination of magistrates and judges and acts as a disciplinary body. The legal system of Cameroon consists of the Supreme Court, two courts of appeal, and high courts as well as circuit courts. The Supreme Court decides whether a bill is receivable by the National Assembly in the event of a dispute between the president and the legislature. It also passes judgment on appeals concerning administrative actions of the government and decisions of the Court of Appeal. The Court of Impeachment passes judgment on the president in case of high treason and on other government ministers in the event of a plot against the government.

Education. Educational services have expanded. About three-fourths of all children of primary-school age are enrolled either in government or in Christian mission schools. This attendance rate is not constant throughout the country, however, because the availability of school facilities varies regionally; virtually all children in the south may attend school, but adequate facilities exist for only about two-fifths of the children in the north.

There are general-education secondary schools, vocational schools, and teacher-training schools. Manual labour is compulsory in secondary and technical schools as a means of encouraging graduates to take up farming instead of seeking white-collar jobs in the cities. The University of Yaoundé was established in 1962 and in the early 1980s added four regional campuses.

Health and welfare. Malaria is prevalent everywhere except in the mountainous regions, where respiratory and pulmonary diseases and dysentery are common. There are incidences of leprosy and schistosomiasis, as well as syphilis, sleeping sickness, and rheumatism. The infant mortality rate, at about 100 per 1,000 live births, remains high by world standards but is nonetheless comparatively low for western Africa.

The government emphasized the improvement of the nation's health facilities in the first and second five-year development plans and increased the number of hospitals, dispensaries, and elementary health centres about sevenfold. Hospitals in major cities were modernized, and in the late 1980s the country had one of the lowest population to hospital bed ratios in western Africa. A Health Sciences University Centre was established at the university in 1969 to train physicians and other medical personnel.

There is no government system of social security covering the whole population. Most assistance is obtained through the traditional kinship system. The National Social Insurance Fund, financed by employee and employer contributions, provides limited pension benefits for wage employees. There are, however, indemnities for occupational diseases or accidents, and the Public Health Service provides free services to the poor.

Cultural life. Each major ethnic group of the country has developed its own culture. The vigorous rhythms played on the drums by the people of the southern forest region contrast with the flute music of northern Cameroonians. In the Adamawa area, the Muslim Fulani produce elaborately worked leather goods and ornate calabashes (gourds used as containers), and the Kirdi and the Matakam of the western mountains produce distinctive types of pottery. The powerful masks of the Bali, which represent elephants' heads, are used in ceremonies for the dead, and the statuettes of the Bamileke are carved in human and animal figures. The Tikar people are famous for beautifully decorated brass pipes, the Ngoutou people for two-faced masks, and the Bamum for smiling masks.

Cultural institutions and organizations

L'Institut Français d'Afrique Noire (French Institute of Black Africa) maintains a library in Douala that specializes in the sociology, ethnology, and history of Africa. Of the several museums, the Diamare and Maroua Museum has anthropological collections relating to the Sudanese peoples, and the Cameroon Museum of Douala exhibits objects of prehistory and natural history.

Cultural organizations include the Cameroun Cultural Association, the Cameroun Cultural Society, and the Federal Linguistic and Cultural Centre. There are also numerous women's associations, youth organizations, and sporting associations.

HISTORY

Early history. From archaeological evidence it is known that humans have inhabited Cameroon for at least 50,000 years, and there is strong evidence of the existence of important kingdoms and states in more recent times. Of these, the most widely known is Sao, which arose in the vicinity of Lake Chad, probably in the 5th century AD. This kingdom reached its height from the 9th to the 15th centuries, after which it was conquered and destroyed by the Kotoko state, which extended over large portions of northern Cameroon and Nigeria. Kotoko was incorporated into the Bornu empire during the reign of Rābiḥ az-Zubayr (Rabah) in the late 19th century, and its people became Muslims.

Islām became a powerful force in the northern and central portions of the country through conquest, immigration, and the spread of commerce from north and northwestern Africa. The most significant bearers of this faith, the Fulani, entered northern Cameroon beginning in the 18th century. The first small groups of pastoralists were welcomed by the host populations. Eventually the Fulani, frustrated under non-Muslim rule and encouraged by the teachings of the mystic Usman dan Fodio, revolted. In the early 1800s Modibbo Adama was appointed by Usman to lead a jihad over large areas centred in northern Nigeria, which were incorporated into Usman's Sokoto empire.

The Fulani expansion reached its southernmost point with the conquest of Bamoum, a kingdom founded in the 17th century by Nshare, the son of a Tikar chief. Bamoum was one of the largest of numerous kingdoms that emerged in the grassland areas of Cameroon at least 300 years ago. The Fulani conquest was brief and did not result in Islāmization, although this faith was accepted by a later ruler, Sultan Njoya, in the early 20th century.

Islām was a significant influence entering Cameroon from the north; other powerful influences entered from the southern coastal region. In 1472 the Portuguese Fernão do Pó was the first European to view the Cameroon coast, although Hanno, a Carthaginian, may have sailed there 2,000 years earlier. Pó was followed by traders, many of whom were involved in the Atlantic slave trade. Cameroon became a significant source, with slaves sold and traded at Bimbia, Douala, and other ports. Routes linked these ports far inland where the Bamileke, Bamoum, and other kingdoms provided the needed supply of slaves. In the early 1800s the slave trade declined, and attention turned to "legitimate" trade in rubber, palm oil, and other items. Earlier Portuguese and Dutch influences were largely replaced by the British and the Germans.

Christian missionaries were also becoming a factor. Under the leadership of Alfred Saker, a Briton, and West Indians such as Joseph Merrick, a Baptist station was established in 1845 at Akwa Town (now Douala). Saker established a larger post at Victoria (now Limbe) in 1858. The American Presbyterian mission opened a station in 1871. The origin and denomination of the missions changed frequently, but the Presbyterians, Baptists, and Roman Catholics have been the most important.

In spite of the predominant role of the British along the coast, in 1884 the Germans claimed the region. The explorer Gustav Nachtigal arrived in July 1884 to annex the Douala coast. The Germans moved inland over the years, extending their control and their claims. Initially, their major dealings were with African traders, but direct trade with the interior promised greater profits, and colonial power was used to break the African monopoly. Plantation agriculture was another major German economic activity. Large estates were established in southwestern Kamerun to provide tropical produce for Germany. Traders, plantation owners, and government officials competed for labour, and force was used to obtain it. The system established was harsh, and many workers died serving German interests.

The mandates. In World War I British, French, and Belgian African troops drove the Germans into exile, beginning a period of British rule in two small portions and

French rule in the remainder of the territory. These League of Nations mandates (later United Nations trusts) were referred to as French Cameroon and British Cameroons.

The British trust territory consisted of a strip of land bisected by the Bénoué River along the eastern border of Nigeria. British rule was a period of neglect. This, coupled with the influx of numerous Nigerians, caused great resentment. The old German plantations—eventually united into a single parastatal, the Cameroon Development Corporation—were the mainstay of the economy. Development also occurred in peasant agriculture, especially in the latter years of British rule. Production of cacao, coffee, and bananas grew rapidly.

The French territory had an administration based on that of the other territories of French Equatorial Africa. Greater agricultural development took place in French Cameroun. Limited industrial and infrastructural growth also occurred, largely after World War II. At independence French Cameroun had a much higher gross national product per capita, higher education levels, better health care, and better infrastructure than British Cameroons.

Although there were differences in the French and British colonial experiences, there were also strong similarities. Most important, these rulers continued drawing Cameroon into the international economic system. By the time of independence, the trusts produced raw materials for European industries but were dependent on Europe, and especially France, for finished goods. This fragile economic situation has continued to plague Cameroon.

After World War II, developments in Cameroon and Europe led to independence. In British Cameroons the major question was whether to remain with Nigeria or to rejoin Cameroun. In a UN-supervised plebiscite in 1961, the south decided to reunify with French Cameroun to become the Federal Republic of Cameroon. The north voted to join the Federation of Nigeria.

Independence and unification

In French Cameroun the major question was the type and intensity of the relationship with France after independence. The first nationalist party, the Cameroon People's Union (UPC) led by Felix-Roland Moumie and Reuben Um Nyobe, demanded a thorough break with France and the construction of a socialist economy. French officials suppressed the UPC, leading to a bitter civil war, while encouraging alternative political leaders. On Jan. 1, 1960, independence was granted, with Ahmadou Ahidjo becoming the first president. Ahidjo and his party, the Cameroon Union, pledged to build a capitalist economy and to maintain close ties to France.

Cameroon since independence. Ahidjo centralized power in the capital, Yaoundé, and in one person—himself. Cameroon became an authoritarian, single-party state in which civil rights meant little. The civil war ended slowly and brutally, but the state of emergency continued for years beyond its conclusion. Ahidjo declared nation building to be a major goal, using the fear of ethnic conflict to justify authoritarianism.

Ahidjo's policy of Planned Liberalism was formulated to encourage private investment, with government to play a strong role in guiding development. Expansion of export crops was to provide the foreign capital needed. In the 1973 announcement of the Green Revolution, the government proposed that the country was to become self-sufficient in food and to become the primary food source for its neighbours.

The discovery of exploitable petroleum in the 1970s was a great boost to the economy, and petroleum became the most valuable export. Petroleum revenues were used to increase prices to farmers, to pay for imports of materials and technology, and to build financial reserves. However, petroleum income also paid for expensive, badly planned projects.

Large-scale industrial development projects met with little success. Problems in planning, technology transfer, and market research plagued these projects, and much capital was lost. There was more success in assisting the growth of agribusinesses and small and medium-sized enterprises producing goods for local use. But to a large extent the country still depended on imported industrial goods. Exceptions to this were refined petroleum products, cement,

textiles and clothing, beverages, and aluminum. Expansion of transportation facilities, the development of hydroelectric capability, and tremendous growth in education took place.

In 1982 Cameroon underwent a dramatic political change, and important though less obvious economic changes were under way. In November Ahidjo resigned the presidency, and Paul Biya took office. Ahidjo retained his leadership of the Cameroon National Union (UNC), the sole political party, but the tranquil nature of the transfer did not last. Ahidjo did not expect to end his domination of the political system. He wished to keep overall control while turning over lesser duties to Biya; however, Biya had his own agenda. The showdown took place when Ahidjo tried to assert party domination over the government. Biya had built a coalition that was sufficient to overwhelm Ahidjo, who resigned from the party. A minor coup attempt and, in April 1984, a bloody uprising by the Republican Guard—favoured, if not directed, by Ahidjo or his supporters—followed. Biya prevailed, and Ahidjo's UNC soon became Biya's Cameroon People's Democratic Movement (RDPC). The economy, however, presented major problems. Ahidjo had resigned just before a severe economic crisis developed, and Cameroonians placed the blame on Biya, who was compelled to accept a World Bank structural adjustment program. This program necessitated budget cuts the effects of which rippled throughout the economy. In 1987 Biya admitted that the country faced an economic crisis, but austerity measures continued, and, as part of the World Bank program, the government began to privatize concerns formerly owned by the state.

The fall of Ahidjo

It was not until the early 1990s that Biya, under both domestic and international pressure, sought to develop a more democratic society, and the country remained a single-party state until 1992. In elections held in 1992 and 1997 Biya and the RDPC maintained control of the country, despite ongoing tension that often exploded into violence between Anglophone and Francophone Cameroonians. A long-standing dispute with Nigeria over ownership of the oil-rich Bakasi Peninsula remained unresolved, but the economic restructuring that continued throughout the 1990s placed the economy on a much sounder footing. The country experienced lower rates of inflation and a higher level of economic growth.

(M.W.DeL./Ed.)

For later developments in the history of Cameroon, see the BRITANNICA BOOK OF THE YEAR.

Côte d'Ivoire

The Republic of Côte d'Ivoire (République de Côte d'Ivoire; also called the Ivory Coast) is a republic on the coast of western Africa. With a coastline more than 300 miles (480 kilometres) long, it forms an almost square block of territory with an area of 123,847 square miles (320,763 square kilometres). It is bounded to the north by Mali and Burkina Faso, to the east by Ghana, to the south by the Gulf of Guinea, to the southwest by Liberia, and to the northwest by Guinea. The de facto capital is Abidjan; the administrative capital designate is Yamoussoukro.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* The ground rises constantly as it recedes from the coast, and the northern half of the country consists of high savanna lying mostly 1,000 feet (300 metres) above sea level. Most of the western border with Liberia and Guinea is shaped by mountain ranges, whose highest point is Mount Nimba (5,748 feet [1,752 metres]), which is situated where the borders of the three countries meet.

One of four natural regions, the coastal fringe consists of a strip of land, no more than 40 miles wide, studded with lagoons on its eastern half. Access from the sea is made difficult by the surf and by a long submarine sandbar. Behind the coastal fringe lies the equatorial forest zone that, until a century ago, formed a continuous area more than 125 miles wide. It has now been reduced to an area roughly triangular in shape, with the apex lying a little to the north of Abidjan and with its base lying along the

Natural regions

Liberian border. The cultivated forest zone, which lies to the east of this triangle, consists of forest land that has been partly cleared for plantations, especially along the Ghana border and in the area around Bouaké. The fourth region, the northern savanna, consists of a sparsely populated plateau, offering open ground favourable for stock breeding. About 4,500 square miles in this region have been set aside to form the Komoé (Comoé) National Park.

Drainage. Apart from the Cavalla River, which forms most of the border with Liberia, major rivers from west to east are the Sassandra, the Bandama, and the Komoé, all of which drain southward into the Gulf of Guinea. Because all are broken by numerous falls and rapids, their value for transportation is minimal.

Soils. The forest soils of the south tend to lose their fertility because of excessive leaching and to turn into laterites, but the poorly drained, swampy soils, also found mainly in the south, more readily maintain their fertility and their rich yellowish silico-argillaceous character. In the savanna areas, crustlike "shields," formed as a result of rapid evaporation, alternate with rich black silico-argillaceous soils.

Climate. Equatorial and southern savanna types of climate prevail. North of about 8° N latitude, the southern savanna type of climate occurs, characterized by the parching wind known as the harmattan, which blows from the northeast from December until February. The dry season lasts from about November to March. There is a single rainy season, and the annual total rainfall amounts to approximately 45 inches (1,100 millimetres) in the northeast and centre to 60 inches in the northwest. The region is drier than the rest of the country and, because of the altitude, somewhat cooler. South of 8° N latitude, two rainy seasons occur, and three climatic subdivisions may be discerned. In the coastal fringe, rain falls mostly from May through July and to a lesser extent in October and November, averaging an annual total of about 77 inches at Abidjan; considerable variations are, however, experienced at different places along the coast. Average monthly temperature variation is small, and diurnal temperatures range from about 70° F (21° C) to the low 90s F (mid-30s C). In the forest zones and in the southern part of the savanna region, the rainy seasons are less pronounced. Diurnal temperatures vary between about 60° and 102° F (16° and 39° C), and the relative humidity is often high. On the mountains further west there is no dry season, and rainfall amounts to about 80 inches.

Plant and animal life. The tropical rain forest in the south contains valuable timber species, including African mahogany and iroko (or African teak). An important afforestation centre is the Banco National Park near Abidjan. The animal life of the forest zone differs little from that

Gallery forest along the Bandama River, near Korhogo, Côte d'Ivoire.

of adjoining Ghana, although the larger ungulates (hoofed mammals) are lacking, with the exception of the bongo (a reddish brown antelope) and the forest buffalo. There are also about six kinds of dwarf antelope, ranging from the royal antelope to the yellow-backed duiker; the giant forest hog is widespread (although nowhere common), and the red river hog is locally plentiful. Manatees (herbivorous water animals) probably survive in some rivers. To the north, the savanna woodlands have some 10 species of antelope, as well as lions and occasional herds of elephants. In addition to Komoé National Park in the northeast, which is well stocked with wildlife, the Taï National Park, near the Liberian frontier, is notable for its pygmy hippopotamuses.

Settlement patterns. In the southeastern quarter of the country, most people live in compact villages and towns. The houses are rectangular dwellings of reeds, poles, or dried clay, traditionally covered with thatched roofs, though often today with corrugated iron sheets. The town centres grow quite lively when, every four days, the markets are held. There, the women are the sellers of the produce, which consists mostly of yams—the most basic national staple—corn (maize), the starch root cassava (manioc), peanuts (groundnuts), oil-palm nuts, and other vegetables. Fishermen on the lagoons ply their trade separately, maintaining their own markets. The entire area is divided into petty states with kings and an elaborate hierarchy of ministers and palace officials bearing elegant titles. *(margin: Rural life and regional characteristics)*

Among the Kru and other peoples of the southwestern forest zone, houses may be either rectangular or round, varying according to place rather than to tribe. Dwellings everywhere are clustered around a central open area, though markets are held only in a very few privileged towns. In other places, the central area is an evening meeting place as well as a spot in which "village democracy" is practiced by councils of elders. Women perform the bulk of daily work, both at home and in the fields, where they grow such crops as rice, cassava, bananas, yams, and corn. Rice is a comparatively recent introduction that has not yet been accepted by all. The men engage in hunting, gathering kola nuts and oil-palm nuts, and—on the coast—fishing.

The Malinke people of the northwestern corner of the country, as members of the Mande group, are inheritors of a culture made famous in the 13th to the 16th century by the Mali empire. Long before then, the Mande had effected a regional agricultural revolution, discovering the use of millet, which remains their staple food, and later introducing such other cereals as sorghum and corn. They have cultivated cotton for centuries. Cattle are kept by everyone, but for purposes of prestige and use on ceremonial occasions rather than for economic reasons; little milk is drunk. The men raise livestock and cultivate crops; they may also travel extensively for trade. The Malinke build round huts of mud and sun-dried brick surmounted by a conical thatched roof. Defense is a traditional concern, as is evident from the fences built around dwellings clustered in compounds and from the palisades surrounding large villages or towns. The people recognize a dual authority: on the one hand, the village chief, on the other hand, the chief representative of the linear descendants of the first settlers, a group forming a traditional nobility. Some people are born into certain trades, such as that of musician or *griot* (a historian minstrel).

The rest of the savanna is part of the domain of the Voltaic peoples, many of whom live in neighbouring Burkina Faso. Among them, the Senufo live immediately east of the Mande and have adopted many of their customs. Life in comparatively large villages and specialization on a hereditary basis may have helped them to reach their high level of artistic creation in wood carving and in weaving. All other Voltaic communities are split into dispersed homesteads. In the northeastern corner, some houses are of a peculiar type, found as far away as northern Benin. These are rectangular mud or brick structures crowned with crenellated parapets built around a flat roof, so that each house has some resemblance to a fairy-tale castle. Millet and sorghum are the staple food of all Voltaics;

the men do most of the work. All the people keep cattle, but only those who give them for keeping to outside herdsmen of Fulani origin ever taste milk. The Voltaics are great traders, distinguishing between local-market trading, which is conducted by women, and outside trading, which is conducted by the Dyula (Dioula), a subtribe of the Mande. Each community is run by the head of the main lineage group, who seeks above all to mediate in all disputes so the earth may never be defiled by blood spilling. In addition, the Senufo have chiefs who govern small districts.

One of the many trading ports built by Europeans along the African coast, Abidjan nevertheless has distinctive features of its own. A most striking one is its location on a lagoon, rather than on the sea. Its core is divided by a branch of the lagoon into Abidjan-Plateau, the first European settlement, to the north, and Treichville, the first large African settlement, to the south. The maintenance of physical communications between these quarters is one of the main problems facing the city.

Plateau was recommended for settlement as early as 1898, but no Europeans actually lived there until 1903. Treichville, located behind the fishing village of Anoumabo, owes its importance to the boom in colonial trade that followed World War I. It remained a very small town until 1934, when the seat of colonial government was moved to Abidjan from Bingerville. Treichville, left to African homebuilders, assumed an appearance that still keeps alive the flavour of those comparatively leisurely times. After 1950, when the opening of the 1.7-mile Vridi Canal to the sea marked a new era of economic expansion, urban growth was exceptionally fast. Treichville, connected with Plateau by bridge, reached the saturation point with a gain of 150,000 inhabitants within a decade. Urban growth after 1960 was in all directions. Comprehensive planning was rendered impossible due to the many confining branches of the lagoon waters.

The first planned extension consisted of building a colonial army camp north of Plateau. There, and beyond, Adjamé and Attiécoubé offered an abundance of so-called moderate-rent dwellings, decent at first but fast deteriorating and inconsistent in design with all African traditions of family life. Across the small bay east of Abidjan, Cocody grew up in isolation as an area of expensive housing (including the presidential tower mansion) with a tourist centre with two hotel complexes offering facilities such as gambling and even ice-skating.

Petit-Bassam Island, where Treichville lies, also contains the settlements of Marcory and Koumassi, beyond which Port-Bouët grew up on the seashore, eight miles southeast of Plateau. Squatters helped in developing Yopougon-Attié and Abobo across the bay to the west, and in 1986 Greater Abidjan was organized into these 10 municipalities (each one with an elected council and mayor).

The people. *Ethnic groups.* There are more than 60 tribes, traditionally independent from each other, though larger groups among them may be recognized on the basis of cultural unity. Each one of these groups has tribal affiliations with larger groups living outside the borders of the republic. Thus the Baule, as well as other peoples living east of the Bandama River, are affiliated with the Akan group of Ghana. The lagoon fishermen farther south also have tribal brothers belonging to the same Akan group. The forest people west of the Bandama belong to the same group as the Kru boatmen of Liberia. In the interior, the Kru group is subdivided into tribes tiny in number but scattered over large areas of the forest and kept together by secret societies.

The savanna peoples may be divided into two main groups. The Mande group, which is particularly strong in Mali, is represented by the Malinke farmers and by the Dyula peddlers. The Voltaic group comprises the Senufo as well as the Lobi and Bobo subgroups, who live widely scattered over the northeastern region and across into neighbouring states.

Linguistic composition. All tribal languages belong to one of three subgroups of the Niger-Congo family: Kwa in the south, Mande in the northwest, and Voltaic in the northeast. A trade language, known as Dyula-Taboussi

and akin to the Mande Bambara, is spoken throughout the country by Muslim traders, and *français de Moussa* is popular in Abidjan, but the official language is French.

Religions. Tribal cults continue to predominate among rural communities, but Islām claims the adherence of one-quarter of the population, mostly in the northwest and in Abidjan. The growth of Christianity suffers from the quick rise and fall of prophetic sects, but almost one-third of the population is Christian, mostly Roman Catholic or Methodist.

Demographic trends. Côte d'Ivoire has one of the highest population growth rates in sub-Saharan Africa and in the world. Its high rate of natural increase together with the huge influx of immigrants from the impoverished countries to the north, which its comparatively strong economy attracts, have been the main reasons for its rapid growth. Immigrants constitute about one-fourth of the total population, and, since a large percentage are men, the country has an unnaturally high male-to-female sex ratio. Nearly one-half of the population lives in urban areas, the largest such figure in western Africa, and among the urbanites there is a large French community as well as numbers of Lebanese and Syrians.

The economy. Côte d'Ivoire has a good financial reputation, which it maintained in the 1980s when the government agreed to reschedule its debt over a period from 1993 to 2002, including sums that had benefited from earlier agreements. Ivoirian policy is fundamentally liberal, and investments are welcomed through tax exemptions and legal protection against nationalization. Increased privatization became government policy in the mid-1980s, mainly owing to the fact that the government had participated in too many specialized undertakings in trying to diversify the economy. Previous plans have been revised with the aim of securing self-sufficiency in food and obtaining equipment in exchange for exports rather than by borrowing. In the long run, success will depend on avoiding luxuries and expanding the local market.

Resources. Côte d'Ivoire is primarily noted for its forest resources; it is a major exporter of tropical wood, but timber now follows cocoa and coffee as an export from one of the more developed western African economies. Mineral resources are rather scanty, but offshore petroleum reserves are being exploited.

Agriculture. The forest, even in its present reduced state, remains the most considerable asset of the country. About 30 species of trees are of high commercial value. The most important timber types are sipo (utile) and sambu (obeche), and reforestation has begun at numerous locations.

The forest floor, after clearing, provides a rich soil for the cultivation of edible roots and bananas, as well as of such commercial tree crops as coffee, cocoa (cacao), and rubber. The savanna soils are good for rice and other cereals. Cotton and sugarcane grow in both areas.

Agriculture provides a livelihood for about 60 percent of the labour force, and locally grown subsistence crops meet most rural domestic needs, but urbanization and the growing use of hired labour throughout the country created a demand for foodstuffs other than yams, cassava, plantains, and corn. An acquired taste for bread and beer has led to significant imports of wheat.

Cocoa has become the main export crop, cultivated by more than one-quarter of the population, but in the late 1980s, after overtaking Ghana in cocoa exports, Côte d'Ivoire faced a price collapse combined with increased competition from Southeast Asia. Coffee, though fallen to second place in export value, remains a favourite business for almost all families in the southeast. Though the local coffee is a robusta of low quality, it constitutes a safe investment, enjoying a privileged position on the French market thanks to low production costs and much publicity. Close to the sea, thousands of acres have been planted with coconut trees to increase the production of copra, the dried kernel from which coconut oil is extracted. The same area is also suitable for pineapples, a valuable export crop.

The southwest provides good soils and climate for oil palm and rubber trees. A South American species of hevea rubber tree was introduced in the early 1960s, and the

Urban life (margin note)

Local and export crops (margin note)

cultivation of palm trees for oil was promoted at about the same time. In the north, cotton planting was fostered by teaching the use of higher-yielding varieties and the practice of cotton-rice and cotton-yam crop rotation.

Livestock raising prospers in the northeast, but national needs are also met by imports. Fishing is a traditional occupation in the lagoons, supplying much of the catch for the local market. Though the country has become a major African exporter of tuna, an old distaste for sea fish lessens local consumption.

Industry. Mining has not been regarded as an especially promising field for industrial development in Côte d'Ivoire, despite the known reserves of copper, nickel, bauxite, cobalt, and manganese. Ivoirian territory extends up the slopes of Mount Nimba, well known for iron ore deposits that enrich both Liberia and Guinea, but mining in Côte d'Ivoire has been focused primarily on exploiting gold and diamond deposits. Still, the mining sector has grown, largely because of the increasing importance of the country's petroleum production.

The Ivoirian industrial sector retains much of the legacy of a colonial policy founded on export rather than the much-needed expansion of the local market. As independence meant the end of the French West African federation, Dakar, Senegal, lost its status as the federal capital, and many firms, mostly French but also Lebanese, shifted their headquarters to Abidjan. Many of them were kept at a low level of activity, however, owing to the reluctance to invest capital locally.

Processing and manu- facturing

Ivoirian industry rests on agricultural progress, historically starting between the two World Wars, in the development of timber, cotton, cocoa, and coffee for export. More crops were later added to these as local canning and preserving facilities developed. Palm oil also benefited from this progress, leading to the production of edible oils and of soap. Timber was used for furniture, cotton fabrics for garments, and sisal for string; and imported raw materials were shipped to local bakeries and breweries.

Power is supplied primarily by hydroelectricity. The main achievement in this field is the dam and power station erected at Kossou, near where the two branches of the Bandama merge. All four main rivers of the country may be harnessed through existing projects.

Finance. The monetary unit of Côte d'Ivoire is the CFA (Communauté Financière Africaine) franc, issued by the Central Bank of West African States, the bank of issue for member countries of the West African Economic and Monetary Union (Union Économique et Monétaire Ouest Africaine; UEMOA). There is also a wide variety of foreign and domestic banks and credit institutions and real-estate agencies. UEMOA's regional stock market is located in Abidjan.

Trade. A regional common market, UEMOA was formed in 1994 and has removed tariff and trade barriers between its members. Côte d'Ivoire also is a party to the Cotonou Agreement, a development and trade policy between the European Union and the African, Caribbean, and Pacific states. Cacao is Côte d'Ivoire's most valuable export; together with petroleum and petroleum products, it accounts for the bulk of the country's export earnings. Other important exports include coffee, palm oil, and wood and wood products. Imports include crude and refined petroleum, machinery and transport equipment, food products, and chemicals and chemical products. In addition to the other members of UEMOA, Côte d'Ivoire's principal trading partners are France, The Netherlands, Nigeria, United Kingdom, and Spain.

Transportation. A railway line connects Abidjan with Ouagadougou, Burkina Faso, for which the railway is still vital, though it has lost much of its importance to Côte d'Ivoire. Railroad haulage has decreased significantly, owing to increased use of the road network, one of the densest and best-maintained in sub-Saharan Africa, which focuses upon Abidjan. Paved roads have been extended to replace beaten-earth roads, but much daily local trade is still conducted along the innumerable tracks that crisscrossed the country long before the advent of Europeans.

Roads and harbours

As western Africa's largest container port, Abidjan has separate docking accommodations for passengers and for

goods requiring special care. Another important port is San-Pédro.

Abidjan has a fully equipped international airport, located at Port-Bouët. It is serviced by a number of foreign airlines, including Air Afrique. The national airline, Air Ivoire, serves airports and landing fields in the interior.

Administration and social conditions. *Government.* Côte d'Ivoire was proclaimed an independent republic on Aug. 7, 1960. The 1960 constitution was suspended following the December 1999 military coup; under the new constitution approved in 2000, executive power is vested in the president, who is limited to one five-year term. The president appoints the prime minister and, with the prime minister's recommendations, the Council of Ministers. In addition, there are two other advisory bodies: the Economic and Social Council and the Constitutional Council. There is a single-house legislature, the National Assembly, with 225 members elected for five-year terms. In 1983 Yamoussoukro was officially named the new national capital, but austerity measures have slowed the transfer of government functions, and Abidjan remains the de facto capital.

Executive, legislative, and judicial branches

Côte d'Ivoire has an independent judiciary, with trial and assize courts located in Abidjan, Bouaké, and Daloa. Their judges may be assigned to 25 other towns or be called upon to constitute special labour and juvenile courts. Abidjan also has a court of appeals and a supreme court. For administrative purposes, Côte d'Ivoire is divided into 19 *régions*, which are further divided into *départements* and communes. Each commune is administered by an elected council.

The political system was controlled for 30 years by the Democratic Party of Côte d'Ivoire (PDCI), the only authorized party. It originated as a league of African farmers founded at the end of World War II by Félix Houphouët-Boigny. In 1990 he was forced to accept the legalization of opposition parties and to allow contested presidential and legislative elections. Since then more than 100 political parties have been established.

Education. Educational services expanded considerably after independence. In the late 1970s a project of universal education, assisted by radio and television, brought international attention to the country. Education is free in Côte d'Ivoire. Primary education is compulsory for six years, beginning at age six. Secondary education lasts for up to seven years. About three-fifths of all eligible children attend primary school, but less than one-fourth of those eligible attend secondary school. A university on the French model opened in Abidjan in 1964.

Health and welfare. Ivoirian health services are comparatively better than those of other western African countries, but the risk is still high for contracting bacterial diarrhea, hepatitis A, typhoid fever, malaria, yellow fever, and schistosomiasis. AIDS affects a diminishing but still significant portion of the population. Modern hospitals are located in Abidjan, Bouaké, Daloa, and Korhogo.

Social problems have resulted from an urban population explosion and the instability caused by political upheaval and civil war, adding a new dimension to long-standing problems of unemployment and prostitution. Urban crime, including robbery and rape, is a major problem, especially in Abidjan, where juvenile delinquency is also a factor. The situation is complicated by traditional solidarity, which makes petty thieving hard to control among relatives, tribal brothers, or people working together or living under the same roof.

Cultural life. The cultural milieu has remained split rather more completely than in other African countries between a maze of tribal cultures and a foreign intrusion that was sudden and almost exclusively French. Traditional arts continue to flourish, and the Abidjan museum offers a rich storehouse. The Senufo carve masks, decorate doors with esoteric signs, and dance to the slow, majestic rhythms of drums supported by xylophones. The mountaineers of the Man forest wear masks showing horrifying faces, and they dance at a quick pace governed by the sound of drums and led by stilt-walkers. Versatile Baule artists make gold jewelry and wooden sculptures.

Traditional arts

An Ivoirian literature in French was born in colonial

times at the Ponty High School in Dakar, Senegal. One of its graduates, Bernard B. Dadié, became world-famous for autobiographical reminiscences in novel form. His schoolmates Goffi Jadeau and Amon d'Aby won a large local audience and many followers through their plays for a national theatre. A younger playwright, Zadi Zaourou, launched a chair in African literature at Abidjan University, and Ahmadou Kourouma, a Muslim, inaugurated a new era of the Ivoirian novel with *Les Soleils des indépendances* (1968; "The Suns of Independence"), first published in Canada. The stage reflects public opinion better than the press, which consists of about 20 periodicals, including two dailies, all published in French in Abidjan.

(J.Co./Ed.)

For statistical data on the land and people of Côte d'Ivoire, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

Early history. Abundant archaeological evidence confirms the presence of early man in what is now Côte d'Ivoire. In the medieval era, groups in the north were drawn into the trans-Saharan trade networks of the Ghana and Mali empires. Islām arrived with Malinke merchants as trade expanded. Mali's collapse in the 16th century resulted in a great upheaval that sent waves of migrants southward, founding new kingdoms in the hinterlands of the forest zone. The original inhabitants were either displaced or assimilated by these new groups.

Precolonial kingdoms. Important kingdoms flourished in the precolonial period. In the savanna country, towns developed around communities of Dyula traders. Kong existed for several centuries before Sekou Ouattara and his sons established a new dynasty there in the early 18th century. In 1897, Kong was destroyed by Samory Touré, then involved in creating a new Muslim empire in northern Côte d'Ivoire. The Bouna kingdom was created in the late 17th century by Bounkani, an immigrant from Dagomba (Ghana). It, along with Kong, became a major centre of Islāmic learning.

The wars associated with the rise of Asante (Ashanti) in the late 17th century led to the migration of numerous Akan groups into the forest country of Côte d'Ivoire. Most powerful of the states established was the Abron kingdom of Gyaman founded by Tan Daté. It was conquered by Asante in the 1730s and, despite numerous revolts, remained subject to it until 1875. In much the same circumstances the Anyi kingdoms of Indénié (Ndenye) and Sanwi were founded. A succession struggle in Kumasi, following the death of Asantehene Opoku Ware in 1750, caused the exodus of Queen Abla Poku (Aura Poku) and her supporters into north-central Côte d'Ivoire. They founded the Baule kingdom, remarkable for its blending of Akan and indigenous traditions.

Arrival of Europeans. Until the 19th century, European contact was confined to the coast, where French and Portuguese traders sought slaves and ivory. In the 1830s, Louis-Édouard Bouet-Willaumez began signing treaties with coastal chiefs, allowing France to build forts and trading posts. France withdrew in 1870, but private merchants remained. Arthur Verdier sent explorers north and imported the first coffee plants. By the 1890s, inland penetration by traders such as Marcel Triech-Laplène and military missions such as that of Captain Louis-Gustave Binger in 1887–89 resulted in treaties and French "protectorate" relationships with many groups.

French occupation and conquest

As the European rush to divide Africa accelerated, France claimed Côte d'Ivoire as a colony in 1893. Borders were determined in 1898, following the capture of Samory Touré. Governor Gabriel Angoulvant began the military occupation in 1908. Imposition of forced labour and head taxes led to fierce resistance, especially among the Baule, Anyi, and Abe (Abbey), but France's superior weaponry triumphed, although the colony was not considered "pacified" until 1918. New revolts broke out as France conscripted thousands of Ivoirians to serve with 140,000 other western African soldiers in World War I.

The 20th century and independence. Following World War I, concerted efforts toward economic development were made. The railway was extended to Bobo Dioulasso, which, along with most of Upper Volta (now Burkina Faso), was attached to Côte d'Ivoire in 1933. Schools and Western-style health facilities were introduced, exploitation of the forests was intensified, and Africans were encouraged to plant cash crops for export. By 1939, Africans grew 90 percent of the cacao and 80 percent of the coffee produced in the colony.

Forty thousand Ivoirians fought in the French army during World War II. Between 1940 and 1942 the colony, along with the rest of French West Africa, chose to remain under the Vichy government. Racist legislation, economic discrimination against African planters, increased forced labour, and a depression caused by Britain's naval blockade created enormous discontent. Educated Africans thus welcomed the subsequent Free French regime. In 1944 Félix Houphouët-Boigny and Auguste Denise formed the African Farmers Union (SAA), which, with the support of the colony's governor (André Latrille), secured equal treatment for African planters. Houphouët-Boigny's all-African slate swept local elections in 1945. The following year, with Côte d'Ivoire part of the French Union, Houphouët-Boigny was elected to the French National Assembly, where he spearheaded the law to abolish forced labour throughout the empire. The present borders were set in 1947, when the north reverted to the territory of Upper Volta.

In 1946 Houphouët-Boigny helped found the African Democratic Rally (RDA), which sought equality for Africans. At first harshly repressed, the RDA achieved many of its goals. In 1960 Houphouët-Boigny, who had been a cabinet minister in two French governments, was elected president of the newly independent Côte d'Ivoire. He ruled until his death in 1993 during his seventh term in office. Despite two coup attempts in 1963 and 1973, Houphouët-Boigny had a remarkable ability to reconcile opponents, which sustained the country's peaceful and prosperous relations with France and with its neighbours throughout most of his rule. Political unrest and strained foreign relations were increasingly evident, however, from the late 1980s. Côte d'Ivoire's first multiparty elections were held in 1990, and Houphouët-Boigny managed to defeat challenger Laurent Gbagbo of the Ivoirian Popular Front (FPI) in a presidential election that was unsuccessfully appealed to the Supreme Court. Upon his death in 1993, Houphouët-Boigny was succeeded by Henri Konan Bédié, who, along with the Democratic Party of Côte d'Ivoire (PDCI), was victorious in 1995 elections that were boycotted by most of the opposition. Long-standing ethnic and religious tensions continued to simmer. With tensions escalating, soldiers mutinied in December 1999, and Brigadier General Robert Gueï took control of the country. After a controversial election in October 2000, in which Gueï tried to manipulate the outcome, Gbagbo was eventually installed as president.

(N.E.L./Ed.)

In September 2002 a failed coup ignited civil war, leaving the country divided into the rebel-held north and the government-controlled south. Foreign peacekeeping troops created a buffer zone between the rebels and the Ivoirian government troops. A peace agreement was reached in January 2003, but months of stalemate followed without resolution of the issues at the root of the civil war—including land ownership, the basis for nationality, and qualifications for holding office. Tensions exploded in November 2004 when the government bombed rebel-held areas in the north and accidentally killed French peacekeepers, prompting a French retaliatory bombing and anti-French counterdemonstrations. The UN Security Council then imposed a 13-month arms embargo on Côte d'Ivoire. Talks in South Africa led to a new cease-fire agreement in 2005, but the big differences between the rebels and government remained unresolved.   (Ed.)

For later developments in the history of Côte d'Ivoire, see the BRITANNICA BOOK OF THE YEAR.

Equatorial Guinea

The Republic of Equatorial Guinea (República de Guinea Ecuatorial), on the west coast of Africa, is an independent

state. Formerly Spanish Guinea, a colony of Spain, it consists of Río Muni (also called Mbini), on the continent, and five islands: Bioko (formerly Fernando Po), Corisco, Great Elobey (Elobey Grande), Little Elobey (Elobey Chico), and Annobón. This fragmented republic has a total area of 10,830 square miles (28,051 square kilometres).

Continental Equatorial Guinea, with an area of 10,045 square miles, is a roughly rectangular territory bounded by Cameroon to the north and Gabon to the east and south. Of the small islands near the continental coast, Corisco measures six square miles, and Great and Little Elobey together are less than a square mile. Bioko, off the coast of Cameroon, has an area of 779 square miles. Annobón, a volcanic island, has an area less than seven square miles and lies south of the equator almost 400 miles (640 kilometres) to the southwest of Bioko.

The country obtained its independence on Oct. 12, 1968. The capital of the republic is Malabo on Bioko. Bata is the administrative capital of the mainland.

Equatorial Guinea is beset by regional differences, geographic isolation, a fragile economy, and a lack of trained personnel, in part a legacy from the colonial era.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief, drainage, and soils.* Half of the continental enclave is covered with forests. A coastal plain about 12 miles wide abuts on the coastal hills, which lead to inland plateaus (called *mesetas* in Spanish) that rise toward the frontier with Gabon. There are several ranges of hills. The central range divides the Benito River basin to the north from the southern basin of the Utamboni River. The Niefang-Mikomeseng range north of the Benito River is somewhat lower. All these ranges form segments of the Cristal Mountains in Gabon. The region is divided by the Benito River (known as the Woleu River in Gabon), which runs generally from east to west and is nonnavigable except for the first 12 miles inland. To the north the Campo River (called the Ntem in French-speaking Africa) marks part of the frontier with Cameroon.

In the south, the Muni is not itself a river but the estuary of various rivers of Gabon and southern Equatorial Guinea. To the east the de facto border with Gabon follows the meandering course of the Kié (Kyé) River rather than the legal frontier, which runs along a line 11° 20′ east of the Greenwich meridian. Except for limited hydroelectric power generation and the use of waterpower at some lumbering sites, the rivers of the mainland enclave are not exploited. The coast consists of a long stretch of beach with low cliffs toward Kogo to the south. Equatorial Guinea has no natural harbour, and Mbini and Kogo are no more than rudimentary ports of call for the ships that infrequently visit. Bata, on the other hand, has been enlarged artificially to become one of the country's main ports.

The coastal plain is overlaid by sedimentary deposits. The hinterland is composed primarily of ancient metamorphic rocks that have undergone a lengthy process of leaching and erosion, so that the resulting soils are relatively infertile. Exploration in the waters off the mainland has revealed some reserves of petroleum and natural gas, and there are prospects for their development. Gold, manganese, iron ore, and uranium are thought to exist in commercially exploitable quantities inland.

The main island, Bioko, is about 45 miles long and 22 miles wide. Its extinct volcanic cones, crater lakes, and rich lava soils form a contrast with the landscape of the mainland. In the north Mount Santa Isabel soars to a height of 9,878 feet (3,011 metres); this extinct volcano is the site of a television transmitter. In the centre of the island, Moca Peak and the Moca Heights present an alpine type of landscape. The southern part of the island, remote and scarcely developed, consists of the Gran Caldera range, which is rugged and indented by torrents and crater lakes.

Despite its tortuous relief, Bioko can be productive agriculturally. Torrents are exploited for hydroelectric power; the Musola River provides electricity for much of Malabo. The coast is largely inhospitable, consisting for the most part of a cliff about 60 feet high, broken occasionally by small inlets and beaches. The southern coast is very steep

Agricultural productivity [margin note]

and dangerous to shipping; San Antonio de Ureca, located along this stretch, is the most isolated settlement on the island. Malabo has a relatively good harbour, built on the partially sunken rim of a volcano.

Annobón is an isolated fragment of the republic, about 93 miles southwest of the island of São Tomé in São Tomé and Príncipe and about 400 miles southwest of Bioko. Like the latter, it is a volcanic island but is less high; it consists of a conglomeration of cones of which Mount Santa Mina (about 2,460 feet) is the highest. Not quite four miles long by two miles wide, it is a rugged island with only one settlement of importance. The inhabitants are mostly fishermen who speak a Portuguese patois.

Climate. The climate of both the continental region and the islands is typically equatorial, with high temperatures, heavy rainfall, and much cloud cover most of the year. Local variations are due to differences in altitude and proximity to the sea. The wet seasons in the continental region are from February to June and from September to December. Rainfall is higher on the coast than inland. In Bata the rainiest months are September, October, and November, with rainfall averaging more than 94 inches (2,388 millimetres) a year. At Calatrava, farther south on the coast, it sometimes reaches 180 inches. Inland, however, rainfall diminishes; Mikomeseng, for example, receives only about 58 inches. The average annual temperature is about 79° F (26° C) and is fairly constant throughout the year. The temperature maxima are somewhat lower than in Bioko. The relative humidity, however, is higher than in Bioko.

Bioko has a rather debilitating climate. The so-called dry season lasts from November to March, and the rest of the year is rainy. The average annual temperature of about 77° F (25° C) varies little throughout the year. Afternoon temperatures reach the high 80s F (low 30s C) and drop to only about 70° F (21° C) at night. Most of the time the sky is cloudy and overcast. Extreme rainfall occurs in the south, with rain brought by monsoon winds amounting to about 450 inches a year around San Antonio de Ureca.

Plant and animal life. Continental Equatorial Guinea is covered by dense tropical rain forest that is exploited by the lumbering industry. More than 140 species of wood are found, of which the most important commercially are okume (*Aucoumea klaineana*), African walnut, and various mahoganies. Intensive exploitation close to the coast led the Spanish timber companies to venture deeper into the interior. Reforestation is minimal, and a secondary forest growth has replaced the virgin rain forest. African subsistence farmers clear the land by burning off the vegetation cover, after which they grow cassava, beans, yams, roots, and some cash crops such as coffee and cocoa, to the extent that the heavily leached soils allow. Mangroves fringe long stretches of the coast as well as riverbanks. Bioko has a greater variety of tropical vegetation, including mangroves, and—at higher altitudes—vegetable gardens and pastureland.

The continental region has a rich animal life that includes gorillas, chimpanzees, various rare species of monkeys, leopards, buffalo, antelope, elephants, hippopotamuses, crocodiles, and various species of snakes, including pythons. Insects, including the tsetse fly and the malaria-bearing *Anopheles* mosquito, as well as hosts of ants, beetles, spiders, and termites, abound. Bioko has no big game but has various monkeys, dwarf antelopes, and rodents, as well as the mosquito and other insects.

Varied animal life [margin note]

Settlement patterns. The mainland is sparsely settled by coffee and cocoa farmers who practice traditional methods of agriculture. During the colonial period, Roman Catholic missions did much to encourage the population to construct "corridor" villages by the sides of roads; in most villages the church and the school figure prominently. The region was never a settler colony, and the few European plantations—mostly Spanish or German—that survived the colonial era have been abandoned. After independence an exodus of Spanish technicians occurred, so that the mainland has largely reverted to a subsistence economy. The modern sector of the economy is represented by lumbering and coffee and oil palm cultivation. Bioko, by contrast, is a plantation island; it retained

for several years a larger number of plantation owners and managers and consequently withstood longer than the continental region the effect of independence upon its economy. Before independence there were about 1,900 plantations (known as *fincas*), which ranged in size from 0.4 acre (one hectare) to more than 4,900 acres. The Bubi people, the indigenous population, live for the most part in mission villages in the northern part of the island on the lower slopes of Mount Santa Isabel, as well as in their traditional homeland, the Moca Heights. They gain their living mostly as small farmers and minor civil servants. The workers on the *fincas* were for many years migrant labourers from Nigeria, who served under contract. During the 1960s the Nigerian workers often brought their families, settling in numbers believed to have reached 50,000 to 80,000 by the end of the decade. Political and economic conditions after independence gradually reduced these numbers, despite an agreement with Nigeria in 1972 to recruit new labourers. Reports of slave-labour conditions on plantations and of killings by authorities in the mid-1970s turned this gradual exodus into a flood, further impoverishing Equatorial Guinea's economy.

In 1962 more than 300 plantations occupied over 148,000 acres, leaving about 2,800 acres in the possession of 1,600 African farmers grouped in cooperatives. Some of the larger plantations, employing hundreds of Nigerian labourers and occupying the most fertile land, were local economic powers whose political influence, if subdued, was nevertheless felt by the local Bubi population.

Malabo, the national capital, is a small city standing behind its crater harbour. A rambling tropical city, it has a distinctly Spanish atmosphere—especially in the European district near the cathedral, the mission, and the government house. Farther inland, the African districts were inhabited mostly by Nigerian and other workers who first chose not to return to the mainland. Another town of some importance is Luba, on the southwest coast, linked with the capital by a good paved road that runs through a series of Bubi settlements.

The continental region was settled much later by the Spanish, so that Bata, the main settlement, lacks the amenities of Malabo. Fang migrants from the interior have built new suburbs around this sprawling port city.

The people. *Ethnic composition.* The majority of the population is African, but its composition is complex for a political unit so small in size. The Fang people, who fought their way to the sea in the 19th and early 20th centuries by subjugating the weaker ethnic groups in their path, form about 80 or 90 percent of the population of the mainland region. North of the Mbini River are the Ntumu Fang, and to the south of it are the Okak Fang. Holding political power on the mainland, the Fang tend to migrate to Bioko, where their leaders hold most of the levers of political control. Coastal groups, such as the Kombe, Mabea, Lengi, Benga, and others, have been in contact with European traders much longer, and a limited amount of intermarriage between European and African ethnic groups has taken place, especially on the island of Corisco. Spanish ethnographers refer to these coastal tribes as *playeros* (literally, "those who live on the beach"). Both the Fang majority and the *playero* minority are Bantu.

The original inhabitants of Bioko are the Bubi, descendants of Bantu migrants from the mainland. Contacts with Europeans decimated them, and only a few thousand remained early in the 20th century. They became the most pro-Spanish element of the African population, viewing the end of Spanish rule as a signal for the invasion of their island by the Fang. Certainly, numbers of mainlanders, most of them Fang, have flocked to the island since the mid-1960s, seeking to join the civil or military forces or to receive political patronage. In addition to these two groups, there are Fernandinos, descendants of former slaves liberated by the British during the 19th century who mingled with other emancipated Africans from Sierra Leone and Cuba as well as with immigrants from other western African countries. Formerly constituting an influential bourgeoisie, they lost much of their status both when the Spanish acquired the island and after independence. The inhabitants of Annobón are descended from slaves im-

Nigerian migrant labour

The Bubi

ported by the Portuguese when the island was a dependency of São Tomé; some of them now live on Bioko.

By about 1970, these different strata together constituted a minority on the island, the majority being formed by the Nigerian contract labourers, who lived in compact colonies in Malabo or on the plantations. The repatriation by Nigeria, however, of at least 45,000 workers beginning in 1975, following reports of repressive conditions in Equatorial Guinea, led to extensive realignment of the demographic, social, and labour structures of the island and, indeed, of the country. Additional communities on the island are formed by *crioulos* (of mixed Portuguese and African origin) from the islands of São Tomé and Príncipe; there are also some Cameroonians.

Linguistic composition. While each ethnic group speaks its own language, other linguistic influences are at work. The first is Spanish, the official language, which is taught in schools and used by the press and is the only means of communication common to both Bioko and the mainland. The second influence is pidgin English, which is used extensively in petty commerce and forms the lingua franca on Bioko. Third, as a result of closer economic association with Francophone countries begun in 1983, French became a compulsory subject in schools in 1988 and, along with Spanish, an official language in 1997. A Portuguese patois is also spoken in both Bioko and Annobón.

Religion. While the vast majority of Equatorial Guineans are nominally Roman Catholic, the Bubi and mainlanders often retain traditional forms of worship, which are emphasized in times of crisis. The Mbwiti cult on the mainland, banned by the Spanish authorities, still has adherents. Most churches were closed by presidential order in 1975, and the Roman Catholic church was banned in 1978. These orders were rescinded after the coup in 1979, but many denominations, notably Jehovah's Witnesses, were proscribed once again in 1986.

Demographic trends. The population was reduced by about one-third through the departure of some 110,000 citizens after 1968 and the repatriation of Nigerian workers by 1976. The rates of population increase, density, and life expectancy are lower than those of most other African countries. (R.P./R.J.H.-C.)

The economy. *Resources.* Equatorial Guinea's economy has depended traditionally on three commodities—cocoa, coffee, and timber—but with the discovery and exploitation of significant reserves of petroleum and natural gas from the 1980s, the country's economic profile changed virtually overnight. Petroleum now accounts for nearly four-fifths of Equatorial Guinea's exports and contributes nearly two-thirds of its gross domestic products (GDP).

Agriculture and forestry. Before independence, the Spanish subsidized cocoa and coffee exports to Spain. The high-quality cocoa was the mainstay of the economy of Bioko, which possessed the right soil and climate for its intensive cultivation. Most of Equatorial Guinea's cocoa is still produced on the island. As with other commodities, production declined under the regime of Francisco Macías Nguema (1968–79) because Nigerian and local workers left the cocoa plantations and maintenance, output, and quality declined. Cocoa exports dropped to one-tenth of their former level, and exports of coffee almost ceased from island and mainland plantations, the small production of robusta coffee by Fang farmers in Río Muni alone being marketed. The timber companies are entirely European; there were at one time 30 timber concessions in operation on the mainland. (Ed.)

Bananas are grown on Bioko, where they are exported from the port of Luba. The output of palm oil from mainland plantations has been adversely affected by the unsettled state of the country.

Industry. There is little industry in the country. Some cocoa and coffee processing takes place locally on plantations and in African cooperatives.

Finance and trade. Following the economic collapse of the mid-1970s, imports came to exceed exports. The gap was narrowed only by external aid, which began to increase after 1979. Since independence the national budget has been balanced first by large Spanish subsidies and since 1981 by help from many nations and agencies.

Decline in cocoa and coffee production

A major economic reorientation took place in December 1983 when Equatorial Guinea joined the Customs and Economic Union of Central Africa (UDEAC). The country entered the Franc Zone in January 1985, acquiring a freely convertible currency and more French aid. French economic influence is growing.

Transportation.   The road network on the mainland was adequate for the light traffic it was required to carry before independence, but it deteriorated in the 1970s. Bata is linked with Mbini by a tarred road. There is a cross-country road from Bata, branching at Niefang and Ncue, to Ebebiyin, Mongomo, and Nsoc near the Cameroon frontier. There are no railways. On Bioko the road system is of a higher standard, with a semicircular tarred road linking Malabo and Luba to the eastern Bubi villages.

The main port is Malabo, which is connected to Spanish and other European ports by regular steamer services. The harbour at Bata was enlarged and modernized in the 1980s and is expected to accommodate a growing share of the country's commerce. European Economic Community aid provided a small coaster in the mid-1980s to ply between Equatorial Guinean ports, Gabon, Cameroon, and São Tomé and Príncipe. There is an international airport at Malabo. In 1982 an international airline, Aerolíneas Guinea Ecuatorial, was formed, and construction began on a new international airport at Bata in 1983.

Administration and social conditions. *Government.* According to the constitution of 1982, the system of government is presidential, and all governing bodies are elected by universal adult suffrage. The Council of Ministers is appointed by the president and is responsible to him. The president is selected by universal suffrage for a seven-year term. The State Council includes the chairman of the House of Representatives, the president of the Supreme Tribunal, and the minister of defense. The Supreme Tribunal in Malabo is the highest judicial authority. There are also territorial high courts and courts of the first instance in Malabo and Bata.

In March 1970 all the political parties that existed before independence were merged into a Single National Party, which later changed its name to the Single National Party of Workers. The party was abolished after the coup of 1979, but exiled Equatorial Guineans formed several opposition parties.

In 1983, elections were held for membership in the 41-member House of Representatives. The president chose all candidates and each position was uncontested. In 1987 a new government party, the Democratic Party of Equatorial Guinea (PDGE), was formed. Some exiles were allowed to return in 1988, and a presidential election was envisaged.

Education.   Education is compulsory for all children between the ages of six and 14, but only about half of the children attend school. The primary and secondary levels each consist of six years of schooling. Facilities for higher education are provided through Spanish assistance at Bata and Malabo. Efforts have been made to improve educational opportunities, but illiteracy remains a problem; only about one-third of the population is literate.

Cultural life.   Despite a veneer of Spanish culture and of Roman Catholic religion that is thicker in Bioko than on the mainland, Equatorial Guineans live largely according to ancient customs, which have undergone a revival since independence. Among the Fang of the mainland, witchcraft, traditional music (in which the Fang harp, the xylophone, the great drums, and the wooden trumpet are used), and storytelling survive. Spanish aid is much oriented to educational and health services. Among the Bubi farmers of Bioko, some ancient customs are still followed.

HISTORY

The island of Bioko (formerly Fernando Po) was sighted by Fernão do Pó, probably in 1472. At first it was called Formosa (Beautiful). Annobón was probably sighted by Ruy de Sequeira on a New Year's Day (hence the name, which means "good year") between 1472 and 1475, most likely that of 1474. By the Treaty of Tordesillas (June 7, 1494), the Portuguese had exclusive rights in Africa, and it was not until 1778 that they agreed to cede to Spain the islands of Annobón and Fernando Po as well as rights on the mainland coast between the Ogooué and Niger rivers. These cessions were designed to give Spain its own source of slaves in Africa for transport to Spanish America, where, in exchange, the Spanish confirmed the rights of the Portuguese west of the 50° W meridian in what is now Brazil. The Spanish were soon decimated by yellow fever on Fernando Po, and they withdrew in 1781. No occupation was made on the mainland.

British administration. After the British abolition of the slave trade in 1807, bases were required by the Royal Navy for the effective suppression of the trade. Fernando Po was unoccupied and lay in a strategic situation from which the Niger mouths and the Slave Coast could be watched for slavers. In 1827 the Spanish leased bases for this purpose to the British at Port Clarence (later Santa Isabel, now Malabo), a fine deepwater harbour on the north coast, and in San Carlos Bay on the west coast.

In the absence of the Spanish, the British also became responsible for administering the island. Thereafter, the British landed many freed slaves, in default of knowing their origin or of being able to repatriate them. Freed slaves also went to the island from Sierra Leone and Jamaica, and in the 20th century the descendants of these several groups continued to speak a form of English. Because of the existence of these freed slaves and the absence of any Spanish administration in the area, the United Kingdom made several unsuccessful offers to Spain for the purchase of Fernando Po—*e.g.,* from 1839 to 1841. In 1843 the Royal Navy concentrated its antislavery patrol at Freetown in Sierra Leone, and its buildings on Fernando Po were sold to a Baptist mission.

Spanish Guinea.   In 1844 the Spanish made a second effort at effective occupation of Fernando Po, and their first exploration of the mainland was carried out in the two decades ending in 1877. Meanwhile, the Spanish had expelled the British Baptists from Fernando Po in 1858, and in 1879 they began to use it as a penal settlement for Cubans. Following the Spanish-American War of 1898, Spanish Guinea remained as Spain's last significant tropical colony. Profiting from the weakness of Spain, France was able to confine mainland Spanish Guinea to its present limited extent. Economic development started only at that time and was concentrated on the richer and healthier Fernando Po. The mainland received significant attention from Spain only after the Spanish Civil War of 1936–39.

In 1959 the status of Spanish Guinea was changed, and the region was reorganized into two provinces of overseas Spain, each of which was placed under a civil governor. The citizens, including the Africans, were granted the same rights as those enjoyed by the citizens of Spain. In 1963 a measure of economic and administrative autonomy for the two provinces (which were henceforth known as Equatorial Guinea) was agreed on by plebiscite.

Independence.   The movement toward independence began to take shape at the end of 1967. Early the following year the Spanish government suspended autonomous political control and, with the subsequent approval of the Organization of African Unity (OAU), proposed that a national referendum be held to approve the new constitution. The constitution was overwhelmingly approved on August 11 and was followed by parliamentary elections in September and by the proclamation of independence on Oct. 12, 1968.

The first president was Francisco Macías Nguema. After his election in 1971 he assumed wide powers and pushed through a constitution that named him president for life in July 1972. He assumed absolute personal powers in 1973 when the island of Fernando Po was renamed in his honour. He controlled the radio and press, and foreign travel was stopped. In 1975–77 there were many arrests and summary executions, which brought protests from world leaders and Amnesty International. The Nigerian government repatriated its nationals in 1976.

Macías was overthrown in 1979 by his nephew, Lieutenant Colonel Teodoro Obiang Nguema Mbasogo, who led a Supreme Military Council to which he added some

Arrival of freed slaves

Role of ancient customs

civilians in 1981. A less authoritarian constitution was instituted in 1982, followed by an election of 41 unopposed candidates to a House of Representatives in 1983.

(R.J.H.-C.)

Yet there was no suggestion that Obiang would willingly give up power, and in the years leading to the 21st century the president repeatedly won reelection by lopsided margins in ballots that were fraught with accusations of governmental fraud. Further, accusations abounded that a clique surrounding the president had pocketed the bulk of the country's burgeoning oil revenue. (Ed.)

For later developments in the history of Equatorial Guinea, see the BRITANNICA BOOK OF THE YEAR.

Ghana

Ghana is a western African republic situated on the coast of the Gulf of Guinea. It has an area of 92,098 square miles (238,533 square kilometres). Although relatively small in area and population, Ghana is one of the leading countries of Africa, partly because of its considerable natural wealth, and partly because it was the first African country south of the Sahara to achieve independence from colonial rule and to embark on its own extensive educational and industrialization programs.

Ghana, which achieved independence on March 6, 1957, consists of the former British colony of the Gold Coast and the part of Togoland that was formerly a UN Trust Territory under British administration. It is bordered to the northwest and north by Burkina Faso, to the east by Togo, to the south by the Atlantic Ocean, and to the west by Côte d'Ivoire. The capital is Accra.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief and drainage.* Relief throughout Ghana is generally low, with elevations nowhere exceeding 3,000 feet (900 metres). The southwestern, northwestern, and extreme northern parts of the country consist of a dissected peneplain—a land surface worn down by erosion to a nearly flat plain, later uplifted and again cut by erosion into hills and valleys or into flat uplands separated by valleys; it is made of Precambrian rocks (from 570 million to 3.8 billion years old). Most of the remainder of the country consists of Paleozoic deposits (from 245 to 570 million years old), which are thought to rest on older rocks. The Paleozoic sediments are composed mostly of beds of shales (laminated sediments consisting mostly of particles of clay) and sandstones in which strata of limestone occur in places. They occupy a large area called the Voltaian Basin in the north-central part of the country where the elevation rarely exceeds 500 feet. The basin is dominated by Lake Volta, an artificial lake that extends far into the central part of the country behind the Akosombo Dam and covers 3,275 square miles. Along the north and south, and to some extent along the west, the uplifted edges of the basin give rise to narrow plateaus between 1,000 and 2,000 feet high, bordered by imposing scarps. The most outstanding are the Kwahu (Mampong) Scarp in the south and the Gambaga Scarp in the north.

Surrounding the basin on all of its sides, except in the east, is the dissected Precambrian peneplain, which rises to elevations of 500 to 1,000 feet above sea level and contains several distinct ranges as high as 2,000 feet.

Along the eastern edge of the Voltaian Basin, and extending from the Togo border to the sea immediately west of Accra, is a narrow zone of folded Precambrian rocks running northeast to southwest, forming the Akwapim-Togo Ranges, which vary in height from 1,000 to 3,000 feet. The highest points in Ghana are found there, including Mount Afadjato (2,903 feet; 885 metres), Mount Djebobo (2,874 feet), and Mount Torogbani (2,861 feet), all situated east of the Volta River near the Togo border. These ranges are part of the Togo-Atakora Mountains, which extend northward into Togo and Benin.

The southeastern corner of the country, between the Akwapim-Togo Ranges and the sea, consists of the gently rolling Accra Plains, which are underlain by some of the oldest Precambrian rocks known—mostly gneisses (coarse-grained rocks in which bands containing granular

minerals alternate with bands containing micaceous minerals); in places they rise above the surface to form inselbergs (prominent steep-sided hills left after erosion). The only extensive areas of young rocks less than 136 million years old are in the wide, lagoon-fringed delta of the Volta, about 50 miles (80 kilometres) east of Accra, and in the extreme southwest of the country, along the Axim coast.

In the east the predominant rocks are less than 65 million years old, though there is a patch of Cretaceous sediments (from 66.4 to 144 million years old) near the Ghana-Togo border. To the west of Axim, near the Côte d'Ivoire frontier, the rocks date to the Cretaceous period. The intervening coastal zone between eastern and western extremes contains patches of Devonian sediments (from 360 to 408 million years old). With the older and more resistant rocks of the Precambrian peneplain, these form a low, picturesque coastline of sandy bays and rocky promontories.

The drainage system is dominated by the Volta River basin, which includes Lake Volta. Most of the other rivers, such as the Pra, the Ankobra, the Tano, and a number of smaller ones, flow directly south into the sea from the watershed formed by the Kwahu Plateau, which separates them from the Volta drainage system. South of Kumasi, in the south-central part of the country, is Ghana's only true natural lake—Bosumtwi—lying in a deep basin without any outlet to the sea. It is believed to be of volcanic origin, although theories of a possible meteorite origin have also been advanced. Along the coast are numerous lagoons, most of them formed at the mouths of small streams.

Over much of the surface of Ghana, the rocks are weathered, and great spreads of laterite (red, leached, iron-bearing soil) and lesser spreads of bauxite and manganese are found on the flat tops of hills and mountains. Although the movements of the Earth's crust that produced the basic geologic structure of the country have now virtually ceased, periodic earthquakes occur, especially near Accra along the eastern foot of the Akwapim-Togo Ranges, where there is a major fault line.

Soils. Throughout the country, weathering, leaching, and the formation of laterite hard pans (hard impervious layers, composed chiefly of iron and aluminum oxides cemented by relatively insoluble materials) by capillary movement (the movement of water containing mineral salts to the surface) and evaporation, are common processes that vary in importance according to the characteristics of each locality. Leaching is more pronounced in the wet south, while the formation of laterite is more widespread in the drier north. In general, most soils are formed in place from parent rock material that has been subjected to prolonged erosion and consequently has limited fertility.

In the forest zone the soils are mostly lateritic. They are subdivided into relatively fertile and less acidic ochrosols (red, brown, and yellow-brown, relatively well-drained soils) in areas of moderate rainfall and into more acidic and less fertile oxysols in the extreme southwest, where annual rainfall exceeds 65 inches. Ochrosols occur over considerable areas in the coastal and northern savanna zones. As in the forest zone, they are the best soils for agriculture.

The coastal savanna zone has an abundance of soil types, including tropical black earths, tropical gray earths, acid vleisols, and sodium vleisols. Except for the tropical black earths, known locally as Akuse clays, most of these soils are of little importance agriculturally. The Akuse clays fill a broad zone across the coastal savanna plains; although heavy and intractable, they respond well to cropping under irrigation and mechanical cultivation.

Because of their intrinsic poverty in nutrients, most of the soils depend heavily on the humus supplied by the vegetation cover. There is, thus, a delicate balance between vegetation and soil fertility, which may be upset by uncontrolled burning or overuse.

Climate. Ghana's climate, like that of the rest of the Guinea Coast, is determined largely by the interplay of two air masses: a hot, dry continental air mass that forms over the Sahara and a warm, humid maritime tropical air mass that forms over the South Atlantic. Both air masses

The Voltaian Basin

The rivers

move toward the equator with their hemispheric winds and meet at the Guinea Coast for several months each year. Continental air moves southward with the northeast trade winds, known in western Africa as the harmattan, and maritime tropical air moves northward with the southwest trades. The zone where these air masses converge is characterized by seasonal line squall rainfall. The convergence zone itself oscillates north and south, following the seasonal movements of the overhead sun and the thermal equator: it reaches its most northerly position in the central Sahara, about latitude 21° N, in August, and its most southerly position about 7° N, a few miles north of the Ghana coastline, in January. Rains occur when the dominant air mass is maritime tropical, and drought prevails when continental air and the harmattan dominate.

Rainfall and temperature

In the savanna country north of the Kwahu Plateau, there are two seasons—a dry season from November to March, with hot days and cool nights under clear skies, and a wet season that reaches its peak in August and September. The mean annual rainfall is between 45 and 50 inches (1,145 and 1,270 millimetres), but there is a marked moisture deficit because of the long, intensely dry season that follows. In the southern forest country, where the annual mean rainfall from north to south has a range of about 50 to 86 inches, there are two rainy seasons—one from April to July and a lesser one from September to November—and two relatively dry periods that occur during the harmattan season, from December to February, and in August, which is a cool, misty month along the coast. In the Accra Plains, anomalously low annual mean rainfall figures vary from 40 inches to less than 30 inches, and the rainfall variability and the vegetation bear close resemblance to conditions in the northern savanna zone.

Temperatures show much more regional uniformity. The annual mean temperature is from 78° to 84° F (26° to 29° C), and the daily range only some 10° to 15° F (6° to 8° C) along the coast, and some 13° to 30° F (7° to 17° C) in the north. Average relative humidities range from nearly 100 percent in the south to 65 percent in the north, although during the harmattan season figures as low as 12 percent have been recorded in the north and around Accra. Enervating conditions produced locally by the combination of high temperatures and high humidities are moderated by altitude in the higher parts and by land and sea breezes along the coast. In general, the hottest months are February and March, just before the rains, and the lowest temperatures occur in January or—along the coast—in August.

Plant and animal life. Although soils and biotic factors (*i.e.*, those pertaining to living organisms, including humans) are important, vegetation is primarily determined by rainfall. There are three principal types of vegetation from south to north occurring in the coastal savanna, in the forest zone, and in the northern savanna zone.

The coastal savanna in the southeastern plains around Accra consists of a mixture of scrub and tall grass (mostly Guinea grass), with giant anthills, often 10 to 14 feet high, providing an anchorage for thicket clumps that often include *Elaeophorbia* (a fleshy-leaved plant containing caustic latex) and other drought- and fire-resistant species such as the baobab (*Adansonia digitata*).

The forest zone

In the forest zone (the southern third of the country and the area along the Akwapim-Togo Ranges, where the mean annual rainfall exceeds 45 inches and is well distributed throughout the year without a pronounced dry season), the predominant vegetation is evergreen and tropical semi-deciduous forest. There are tall trees of varying heights, forming a closed canopy at the top, above which tower a few forest giants, such as the silk cotton tree, the wawa tree (African whitewood, a hardwood), and the African mahogany. The evergreen forest is in the extreme southwest, where the rainfall exceeds 65 inches a year, while there is a semi-deciduous forest farther north.

The dense forest zone formerly covered an area of about 30,000 square miles, but farming activities and timber exploitation have reduced it to less than 8,000 square miles, including about 6,000 square miles of reserved forest. To ensure the sustainable use of the country's rapidly diminishing forest resources, the government has embarked on a forestry policy involving the compulsory reforestation of cutover areas and more accurate measurements of exploitable timber and rates of extraction and regeneration.

The third vegetation type, the northern savanna, is found in the northern two-thirds of the country, where the low annual rainfall, between 45 and 30 inches, occurs in a single season and is followed by a period of intense drought. There the vegetation consists mostly of tall Guinea grass, together with a scattering of low trees, such as the shea butter tree, various species of acacia, and baobabs. Along the northern border the savanna gives way to a more open type of grassland that has developed largely as a result of prolonged human interference.

Ghana is relatively rich in animal life, although it has been reduced by hunting and the spread of human settlement. Large mammals include lions, leopards, hyenas, antelope, elephants, buffalo, wild hogs, chimpanzees, and many kinds of monkeys. Among the snakes are pythons, cobras, horned and puff adders, and green mambas. Crocodiles, the endangered manatees, and otters are found in the rivers and lagoons. Hippopotamuses are found in the Volta River. There are many species of lizards, tortoises, and giant snails.

Among the numerous birds are parrots, hornbills, kingfishers, eagles, kites, herons, cuckoos, nightjars, sunbirds, egrets, vultures, snakebirds, and plantain eaters.

The ocean, rivers, and inland lakes are rich in fish and other forms of life. Sardines, locally called herring, arrive seasonally in the coastal waters in large shoals; other fish include mackerel, soles, skates, mullet, bonitos, flying fish, lungfish, elephant fish, sea bream, and sharks. Edible turtles, barracuda, and stingrays are fairly common; mussels, crabs, lobsters, and prawns also are found.

Fish and other aquatic life

Insect life is particularly abundant. There are beetles, fireflies, ants, termites, butterflies, crickets, and bugs. Among the most dangerous insects are mosquitoes, tsetse flies, and blackflies (Simuliidae), which are responsible for transmitting the endemic diseases of malaria and yellow fever, trypanosomiasis (sleeping sickness), and onchocerciasis, or river blindness (a parasitic disease), respectively.

The Mole National Park in the western part of the Northern Region near Damongo is 1,900 square miles in extent. Other reserves have been developed farther south, notably on some of the islands in Lake Volta.

Settlement patterns. Ghana has three major geographic regions—coastal, forest, and northern savanna—the boundaries of which are not always clearly defined.

The coastal zone is traditionally a region of fishermen and small-scale farmers. The region was formerly occupied by a series of small kingdoms, the inhabitants of which were the first to be exposed to European contact—from the 15th century onward, perhaps even earlier. From east to west the principal ethnic groups are the Ewe, Adangme (Adangbe), Ga, Efutu, Fanti, Ahanta, and Nzima. The seaboard has made the region an important centre for commerce, causing population concentration in such urban centres as Accra, Cape Coast, and Sekondi-Takoradi. The coastal zone has more urban centres than any other region in Ghana.

Farther inland, occupying about a third of the country, is the forest region with its relatively large and prosperous traditional states and rich agricultural lands. West of the Volta these states consist mostly of Akan peoples; to the east the Ewe predominate. The forest environment and the economic activities and modes of life engendered by it, especially since the introduction of cocoa farming in 1879, have served to give the region a common stamp. Apart from the Ewe, the major ethnic groups are the Akwapim and Kwahu in the east, the Akim in the south, the Ashanti and Brong in the centre and north, and the Wasaw and Sefwi in the west. While all the peoples in the region have a relatively long history of settlement and political activity, those with the most impressive record are the Asante (Ashanti), who from the 17th to the late 19th century built a political empire centred on Kumasi, the present Asante capital, that included a large number of subject and satellite states spread throughout the region and in both the coastal and northern savanna zones.

The Asante

Almost all the timber, cocoa, and exploited mineral

wealth, as well as a number of minor cash crops grown for export, and a large part of the foodstuffs consumed in Ghana come from this region. Population density is relatively high, especially in the cocoa-growing areas. Except for Kumasi, there are few really large urban centres, although the region's other administrative centres—Ho, Koforidua, and Sunyani—form significant population concentrations.

The northern savanna region covers some two-thirds of the country but is economically the least developed region. The largest ethnic groups are the Dagomba and the Guang (Gonja), related to the Mossi people of Burkina Faso. The region has a harsh environment because of its low rainfall. The southern part immediately adjoining the forest zone, forming part of the disease-ridden "middle belt" of western Africa that combines the worst features of the forest and the savanna environments, is especially unattractive for settlement. In the past it was subject to extensive slave raiding from both north and south. Its distance from the sea and consequent insulation from active European contact over a long period retarded the development of the northern region.

Among the advantages of the northern region, especially in the most northerly part, which is relatively free from the tsetse fly so deadly to cattle, is an extensive savanna vegetation that is well suited to livestock breeding. Its relatively light soils and the rainfall regime favour the cultivation of yams and cereals. Although agriculture is mostly of the traditional subsistence type, irrigation and mechanized cultivation have opened up new prospects. Lake Volta, which extends far into the heart of the region, offers comparatively cheap communication with the south and serves as a reservoir of water for agricultural and other uses.

The pattern of rural–urban settlement

By the late 1980s only about one-third of Ghana's population was estimated to be urban, but there is a steady and increasing migration from the rural areas into the urban centres, some of which are expanding at about double the national population growth rate. Despite their rapid expansion in size and population, most of the urban centres remain small by world standards. The Accra–Tema agglomeration, with a population of more than one million, is the largest in the country, followed by Kumasi and Tamale.

Almost everywhere agriculture is extensive, rather than intensive, and rural settlements form scattered nuclei surrounded by land that is either under crops or is undergoing regeneration. Permanent or continuous cropping is encouraged throughout the country but is most common in the extreme northeast, where settlements consist of isolated compound houses, each surrounded by its own farm. Elsewhere, agriculture is based on a rotational system in which land is cropped for two or three years and then abandoned for from four to seven years, in order to allow it to regenerate. When cocoa or other tree crops are grown, however, cultivation is usually permanent.

The people. *Ethnic and linguistic groups.* Ethnically, the people of Ghana may be said to belong to one broad group within the African family, but there is a large variety of tribal, or subethnic, units. On the basis of language, it is possible to distinguish at least 75 different tribes. Many

The largest tribal groups

of these are very small, and only 10 of them are numerically significant. The largest groups are the Akan, Mole-Dagbani, Ewe, Ga-Adangme (Ga-Adangbe), and Gurma. Despite its tribal variety, there were no serious tribal dissensions when Ghana became independent. Tribal consciousness persists in many areas, however, and at times tensions have erupted, especially in northern Ghana, into violent clashes with many fatalities. At all levels in government and in public life, an effort has been made to play down tribal differences, a policy that has been helped by the adoption of English as the official language.

Practically all the present tribes are believed to have moved into the country within the last 700 to 1,000 years in a series of migrations from the north, with the Ewe and Ga-Adangme, who occupy the southeastern corner of the country, entering from the east and southeast.

Religious groups. Nearly two-thirds of the population is Christian, about one-sixth is Muslim, and one-third

adheres to the traditional tribal religions. Although the indigenous religions are widespread and deep-rooted, they lack a systematic body of doctrines. Though they are based, in general, on belief in the existence of a supreme being, a number of lesser deities associated with various natural phenomena are recognized. Considerable prominence is given to dead ancestors, who are considered to be ever-present, capable of influencing the course of events for the living, and capable of serving as intermediaries between the living and the gods.

Christianity has steadily gained ground at the expense of the indigenous religions. Christian influence is most dominant in the southern part of the country, while Islām is strongest in the extreme north and in the larger urban centres, which contain some immigrant populations from Muslim regions of western Africa. Since the 1950s many spiritualist churches claiming adherence to Christianity have appeared. The main divisions of the Christian church, however, are still the Roman Catholics, Methodists, Presbyterians, and smaller denominations.

Demographic trends. The country's population has, since 1970, maintained a high average annual growth rate of about 3 percent, with females slightly in excess of males. More than 60 percent of Ghanaians are under 25 years of age, assuring that the country's high growth rate will continue for some time. Life expectancy, which in 1960 was placed at about 46 years, has improved considerably and, at nearly 55 years in the late 1980s, was among the highest in western Africa.

Population fluctuations due to emigration became pronounced during the severe economic depression of the late 1970s and early 1980s. The expulsion of more than one million Ghanaian nationals, mostly young people without employable skills, from Nigeria in 1983 delivered a further shock to the economy but failed to cause major sociopolitical upheavals, owing largely to the built-in absorptive capacity of Ghana's indigenous social systems.

The economy. The economy is a mixture of private and public enterprise. National income is derived primarily from agricultural and mineral output and only to a limited extent from manufacturing and services. Most of the cash crops and mineral products are for export.

Before independence the government's role was confined mainly to the provision of such basic utilities as water, electricity, railways, roads, and postal services. Agriculture, commerce, banking, and industry were almost entirely in private hands, with foreign interests controlling the greater share in all of them except agriculture.

Shortly after independence, the government set out to extend its control over the economy by setting up a large number of state-owned enterprises in agriculture and industry. In order to make up for the local shortage of capital and entrepreneurial skills, measures were adopted to attract foreign investors to operate independently or in partnership with the government. These policies did not achieve the desired results because of poor planning and corrupt administration. By 1966, when the administration of President Kwame Nkrumah was overthrown, the heavy overseas borrowing upon which the government had relied to support its economic programs had dissipated almost all of the country's overseas reserves and had produced external and internal debts totaling some $1 billion.

Subsequent governments have sought to deal with the adverse balance of payments, to arrest inflation, to secure a rescheduling of overseas debts, to increase agricultural productivity, and to establish industrial development on a rational basis, as well as to save scarce foreign exchange by encouraging exports of locally manufactured goods.

Between 1966 and 1972 there was a marked contraction in governmental involvement in economic matters. The government continued to provide basic utilities and remained the largest single employer of labour. After the coup of 1972 policymakers returned to the concept of a centralized economy. The considerable debt owed to four British companies was repudiated, imports were cut, industrial projects abandoned after the fall of Nkrumah were resuscitated, and a policy of increased nationalization and state control was begun. In 1974, after a two-year suspension of foreign loans and aid, the government agreed

on a schedule for the repayment of its debts. This was accompanied by a more receptive policy toward investment by developed countries, though political instability resulted in a number of erratic economic policies. Ghana's external debt and balance of trade deficit increased and led to a devaluation of the cedi (the national currency) in 1978, a currency conversion in 1979, and a reduction of interest rates and demonetization of lower-value cedi notes in 1982. Under the restructuring program sponsored by the World Bank in the late 1980s foreign companies and private entrepreneurs were encouraged to invest in private or joint private and public ventures and to assist in the rehabilitation of the economy; the trend was toward increased privatization of the economy.

Taxation   A large part of government revenue is derived from various taxes, including a duty on cocoa, import duty, customs and excise duties, sales tax, income tax, property tax, and other taxes. Tax concessions are available to certain classes of business, and special incentives are offered to those generating foreign exchange through exports. In the late 1980s measures were instituted to widen the tax net so as to increase revenue, and subsidies on many goods—especially food items and imported fuel—and on public utilities were drastically reduced.

Despite attempts at reform, excessive bureaucratic controls and inefficiency continue to hamper trade and orderly economic development and to foster a flourishing underground economy. In addition, the massive devaluations of the cedi (from 1.02 cedis to the U.S. dollar in 1970 to 227 cedis to the U.S. dollar in 1989) have had mixed effects on both trade and the cost of living.

Although there is a minimum wage for workers, the gap in wages between the lowest-paid and well-paid workers is still wide. This disparity, coupled with rising living costs and instability in the national currency, impose severe hardships on a large section of the working population.

Trade unions   The trade union movement played a role in the struggle for self-government, and after independence the government, recognizing the importance of the movement as a political force, sought to make it a more direct instrument of policy. All trade unions in the country were brought under the authority of the Trade Union Congress, which was virtually an integral part of the government; this curtailed the freedom of workers to bargain with employers and the government. After the fall of the Nkrumah government, the monopoly of the Trade Union Congress was abolished and other unions were able to function. In 1972 the Trade Union Congress was revived, but the military government in 1982 once again suppressed its activity.

Resources. Although Ghana has a wide range of minerals, only a few—*e.g.,* gold, diamonds, manganese, and bauxite—are exploited. These minerals are found mostly in the southern part of the country. The gold industry, with an unbroken history dating from the 15th century, is the oldest; the others are of 20th-century origin—the working of manganese dating from 1915, diamonds from 1919, and bauxite from 1942. There are important reserves of limestone and iron ore, although they are not exploited. There is an aluminum rolling mill at Tema.

In 1970 oil was discovered offshore between Saltpond and Cape Coast. Although this discovery was initially classified as noncommercial, the steep world oil price increases of 1973–74 caused the government to reclassify it as commercial in 1974 and to undertake development. In 1974 and 1980 substantial amounts of natural gas were discovered offshore to the south and west of Cape Three Points. Oil production in the Saltpond area began in 1978, but it has proved disappointing; all crude oil is exported in order to reduce the country's foreign-trade deficit. Further explorations of a more comprehensive nature were begun in the late 1980s. Salt, in which the country is self-sufficient with a surplus for export, is obtained from the sea and lagoons. There are also extensive supplies of building stone, gravel, and sand.

Biological resources   Biological resources are extensive. The soil and climate favour a wide range of crops. The most important is cocoa, of which Ghana is a leading world producer. Timber and the crops of the forest zone constitute additional important biological resources. Yams and such cereals as rice and millet are produced primarily in the northern savanna zone; cattle are also raised there. The forests yield shea nuts and kola nuts. Ghana's offshore waters are rich in fish, and the creation of Lake Volta added another important source of fish for the domestic market.

Many of Ghana's rivers have the requisite regimes and rates of flow to permit exploitation for hydroelectric power. The Akosombo Dam on the Volta River and a second dam a few miles downstream at Kpong have a combined electrical capacity of more than one million kilowatts. Electricity from Akosombo meets most of the domestic requirements, leaving a surplus for sale to Togo and Benin.

Agriculture, forestry, and fishing. Apart from providing the bulk of national income, agriculture, forestry, and fishing employ more than half of the population. The annual output of cocoa—which is cultivated on more than one-half of Ghana's arable land—provides between three-fifths and three-quarters of the total revenue from exports. Consequently, the world price paid for cocoa directly determines Ghana's economic fortunes. Cocoa production fell sharply during the 1970s. It was undermined by aging and diseased trees, drought, bush fires, poor transport facilities, lack of adequate price and other incentives to farmers, and widespread smuggling across Ghana's borders. The Cocoa Marketing Board was abolished in 1979 following charges of corruption but was reconstituted in 1985 as the Ghana Cocoa Board. The government has repeatedly raised the production price of cocoa in an effort to stimulate production and to decrease the country's balance of payments deficit. These efforts and slight improvements in the world price have had a favourable effect on the economy, but the outlook remains far from promising.

Timber is also an important foreign exchange earner. Ghana's timber marketing is controlled by the Timber Export Development Board. Since the beginning of 1973 all foreign-owned timber export firms have been required to incorporate locally, so that the purchasing of timber is conducted only through this board.

The Ghana Oil Palm Development Corporation built a mill for the production of palm oil on its plantation near Kade. One of the largest in western Africa, the mill is designed to fulfill industrial and domestic consumption needs.

The Ghanaian domestic market is important. The value of food produced for local consumption is considerable. Successive governments have strongly supported diversification of food production to reduce reliance on a few crops and to cut the need for imported foodstuffs, but their measures have often been contradictory because of the emphasis on exports capable of earning foreign exchange. Besides cocoa, timber, and palm oil, other agricultural products that are exported include sugar, coffee, palm kernels, copra, and various fruits and vegetables.

Fishing   The various types of fish caught include cape hake, grunt, sea bream, tilapia, herring, mackerel, barracuda, and tuna. Most of the catch is sun-dried or smoked and consumed locally, but an increasing proportion is refrigerated; certain fishes, especially tuna, are mainly directed toward the overseas market. Government and private research agencies are working to increase the cash income of rural fishing communities and also to modernize the processing, distribution, and marketing of the catch. The State Fishing Corporation and a number of private companies operate a fleet of deep-sea trawlers.

Industry. A policy of industrialization has resulted in the establishment of a wide range of manufacturing industries, producing food products, beverages, tobacco, textiles, clothes, footwear, timber and wood products, chemicals and pharmaceuticals, and metals, including steel and steel products. These are produced mostly for local consumption. Among the announced program directives of a five-year plan (1975–80), however, was the maintenance of a reasonable balance on external trade, and a number of industrial projects were directed to the export market in either the short or long term. Ghana's industrial development has been hampered by a lack of capital, and official industrial development policy in the early 1980s recognized the importance of attracting foreign capital for the purpose of an effective economic take-off.

During the 1960s there was a decline in the mining industry, but in the 1970s increased world market prices for gold and manganese, new discoveries in the Prestea goldfields, and the formation of a National Manganese Corporation in 1975 to carry out a five-year plan to rehabilitate the manganese mines at Nsuta improved prospects for these minerals. The production of bauxite, on the other hand, has been well below capacity, and other minerals, notably diamonds, are close to depletion.

The development of Ghana's mineral industry has been hampered by a shortage of equipment, skilled personnel, and capital in the form of foreign exchange. The mineral industry failed to regain the economic preeminence it enjoyed before the 1960s. In the late 1980s, however,

Renewed mining efforts renewed efforts at revitalization with massive foreign investments and the encouragement of local and foreign private entrepreneurs were begun. Ghana possesses substantial bauxite reserves, though the output, all of which is exported, is less than half of capacity. High-quality sand in the Tarkwa mining area provides the basis for a small but important glass industry. Cement factories have been developed at Tema and Takoradi.

Revenue from tourism has increased gradually, with most of the tourists coming from Nigeria, the United Kingdom, Côte d'Ivoire, the United States, and Germany. The Ghana Tourist Board and Ghana Tourist Development Company supervise the regulation, financing, and development of the tourist industry. Hotels are located at Accra, Tema, Takoradi, and Kumasi, and there is a hotel at Akosombo overlooking Lake Volta.

Transportation. The principal means of transport, in order of importance, are motor vehicles, railways, and aircraft. Animals are scarcely used except in the extreme north, where horses and donkeys are sometimes employed. In recent years there has been a marked rise in the number of privately owned vehicles, especially automobiles.

The density of roads and railways is much greater in the southern part of the country than in the north, and even in the south the cocoa-growing areas and the coastal zone tend to be favoured at the expense of other parts. Only about one-fifth of the country's roads are paved. With foreign aid, rehabilitation of the road network was undertaken in the mid-1980s.

Motor transport, now widespread and popular, was introduced in the towns about 1912 and spread quickly to the cocoa-producing areas. While the railways are owned by the state, motor transport is almost entirely in private hands. The state operates municipal bus services and express coach and freight services between the larger towns.

The Ghana Highway Authority oversees road maintenance and improvement. Road quality ranges from first-class paved (asphalt-surfaced) roads to third-class unsurfaced roads. First-class roads run between the large urban centres; they include the coastal Accra–Sekondi-Takoradi–Axim road, the Accra–Kumasi road, which continues northward to Tamale; and the Accra–Ho, Accra–Keta–Aflao, Cape Coast–Kumasi, and Sekondi-Takoradi–Kumasi roads. A concrete-surfaced motorway with two lanes in each direction runs from Accra to Tema. Second-class roads are narrower than first-class roads and have a base of swish (sun-dried earth) rather than quarried stone.

Rail transport Rail transport was introduced in the early 20th century. The rail system forms a triangle joining Sekondi-Takoradi, Kumasi, and Accra. In addition, a central line runs from Huni Valley, on the Takoradi–Kumasi line, to Kade in the centre of the triangle, and an extension joins Achiasi on this central line with Kotoku on the Accra–Kumasi line. The port of Tema is also linked to the system by a short extension running from Achimota, near Accra. The Takoradi–Kumasi line is also joined by two other branch lines, one running from Tarkwa out to the gold-mining town of Prestea and the other running from Dunkwa to the bauxite-mining town of Awaso. Rail transport is much less popular than road transport. Railways are primarily used for the transport of freight, especially minerals and logs, although even this has declined since the early 1970s as the result of deteriorating facilities.

Small airports located at Takoradi, Kumasi, Sunyani, and Tamale are used solely for domestic services, while the Kotoka International Airport at Accra handles both domestic and international flights. Domestic air services are operated by a state-owned corporation, Ghana Airways, which also operates a western African service linking the coastal states and an international service to the Middle East, Europe, and the United Kingdom. While air transport is popular in Ghana, the maintenance of the national airways is costly and requires a large annual governmental subsidy. Air transport is used predominantly for passengers, but its use for cargo is rapidly expanding.

The importance of sea transport has dwindled with the expansion of air services. Most goods entering and leaving the country, however, are carried by sea. There are two modern harbours, at the ports of Takoradi (opened in 1928) and Tema (opened in 1961). Takoradi specializes in exporting timber, manganese, and bauxite, while Tema specializes in the export of cocoa. Both ports also handle passengers. In terms of tonnage, Tema and Takoradi handle about equal amounts of cargo. The national shipping company, the Black Star Line, Ltd., was plagued by debts, obsolete vessels, and labour disputes, and management was turned over to a West German concern, but management reverted to the government in 1982. Ships from many other countries also use Ghanaian ports; traffic is mostly with Europe, the United States, and East Asia. The Ghana Railway and Ports Authority is responsible for the country's port operations under the Ministry of Transport and Communications.

The creation of Lake Volta occasioned an interruption on the Kumasi–Tamale road, where the Yeji ferry, formerly only a few yards wide, became a crossing of almost seven miles. A number of other ferries across the Volta have completely disappeared. Launch service on Lake Volta has been expanded, however. A launch service is also maintained on the lower reaches of the Volta between Ada and Amedika.

Administration and social conditions. *Government.* The constitution provides for a unicameral parliamentary form of government with a president as head of state and The executive branch a vice president. The president is elected for a term of four years (with the possibility of reelection for one further term) by universal adult suffrage. There is a broadly based Council of State with deliberative and advisory functions, and an elected unicameral Parliament. The president appoints the cabinet, which averages between 20 and 25 members.

Flight Lieutenant Jerry Rawlings led a military coup in December 1981 and became the head of state as chairman of the Provisional National Defense Council (PNDC). The Parliament was disbanded and political parties were prohibited. After much political unrest, a new constitution in 1992 established a multiparty system, and the PNDC was dissolved in 1993.

Ghana is divided into 10 regions: Western, Central, Greater Accra, Eastern, Volta, Ashanti, Brong-Ahafo, Northern, Upper West, and Upper East. After 1972, when the first constitution was suspended, each of the then-existing eight regions (Greater Accra had not yet been created, and Upper West and Upper East formed the Upper region) was administered by a regional commissioner, who was an army officer. The constitution of 1979 revived the local, district, and regional councils, but the military government in 1982 appointed regional secretaries and district secretaries to take charge of the regions and districts and abolished the local councils as previously known. Under the PNDC's proposals for the development of participatory grass-roots democracy, district elections were held in late 1988–early 1989 for the establishment of district assemblies composed of elected and government-nominated members.

The judicial system is based chiefly on the English model, but Ghanaian customary law is recognized as well as English common law. The administration of justice is handled by various courts divided into two groups: the superior courts, consisting of the Supreme Court, the Court of Appeal, and the High Court; and inferior courts, consisting of the circuit courts, the district courts, and other courts provided by law, such as the juvenile courts. After the military government took control the Supreme

Court was abolished, and the Court of Appeal became the highest court. The constitution of 1979 restored the Supreme Court, and the Rawlings government retained it as the final court of appeal. A special tribunal investigates corruption. In 1982 the PNDC established a special military tribunal to hear cases against members of the armed forces and people's tribunals to handle corruption and abuse of public office. The adjudicating authorities in chieftaincy and purely traditional matters are the regional and national houses of chiefs. Appeals from decisions of the National House of Chiefs are made directly to the Supreme Court.

Dating to the period of British colonial rule, chieftaincy and the traditional political authorities have tended to run along parallel lines with the central government. Since independence, this tendency has persisted or even expanded, and the institution of chieftaincy has become increasingly divorced from the exercise of real political power at almost all levels of government; its role now is largely ceremonial.

Education. Ghana has one of the best-developed educational systems and one of the highest adult literacy rates in tropical Africa, but the cost is high. In April 1974 the government began implementation of a new educational system. It consisted of a pre-primary cycle for ages four to six; a basic first cycle, including six years of primary education and three years of junior secondary; and a second cycle of variable length. The second cycle leads to secondary vocational or commercial programs or to a senior secondary course preparing students for university studies or other third-cycle courses in high-level polytechnics and specialized institutions.

The first cycle is free and compulsory; for the first three years education is in the predominant local language, with provision for education in at least one other Ghanaian language and English, the latter being the language of instruction from the fourth year of the primary cycle.

The universities Teacher training and technical education are approximately equivalent to secondary education, though they tend to attract pupils who are not aiming at university careers.

University education is provided at three institutions: the University of Ghana, at Legon, near Accra, established as a university college in 1948 and granted full university status in 1961; the University of Science and Technology at Kumasi, established in 1951 and granted full university status in 1961; and the University of Cape Coast, established in 1962 for the training of science teachers and granted full university status in 1972. All three institutions are financed by the government; there are no private universities. The Tarkwa School of Mines, which is also a government-financed institution, is affiliated with the University of Science and Technology and offers diploma courses in mining and related subjects.

Under the restructuring program of the late 1980s it was decided that more drastic reductions should be made in student subsidies for food and accommodation in third-cycle institutions.

The enrollment in all schools, especially in secondary schools, has soared dramatically since Ghana achieved self-government. There are a number of private schools at both elementary and secondary levels. The number of available places in second- and third-cycle institutions, especially the universities, however, is still far short of the demand from qualified applicants.

Despite the heavy national expenditure on education and the large school population, Ghana still has a relatively low literacy level by world standards. Thanks to the extensive use of the sound and visual media, however, illiteracy is not as serious a handicap as it formerly was. English is widely spoken, especially in the urban areas.

Health and welfare. Major health problems are communicable diseases, poor sanitation, and poor nutrition. The main emphasis of government health policy is on improved public health, and since independence many improvements have been made in nutrition and in maternal and child care. Many of the endemic diseases, such as malaria, pneumonia, and diseases of the gastroenteritis group, which formerly took a heavy toll of life, have been brought under a measure of control as a result of improved hygiene, better drugs, and education. The infant mortality rate has shown a steady decline, especially in urban areas, as a result of improved health care facilities and dietary habits; it is among the lowest in western Africa but remains high by world standards.

There are hospitals and clinics provided by the government and by various Christian missions in most parts of the country. Supplementary services consist of health centres, dispensaries, and dressing stations. Considerable progress has been made in the quantity and quality of health facilities and medical personnel, but rapid population growth continues to impose great pressures on the available facilities. In addition to the large number of doctors in the public service, many private practitioners operate their own clinics and hospitals. Registered doctors and dentists are supported by a paramedical staff of nurses, midwives, and pharmacists, as well as by auxiliaries. There are two medical schools in the country: one in the University of Ghana in Accra and the other in the University of Science and Technology in Kumasi.

Rural community development Government programs of rural community development are assisted by village improvement projects undertaken with the participation of the residents. Welfare and economic aspects outside urban areas are handled by the national government. In the urban areas, welfare services concentrate on casework, probation work, youth activities, and guidance through voluntary organizations. There is a government-sponsored pension plan for wage employees.

With the rapid growth of population and the movement of large numbers of people from the rural to urban areas, housing has become an acute problem, especially in the large cities where the problem is both quantitative and qualitative. In the rural areas the problem is mainly qualitative. There is distinct overcrowding in the urban areas, where the number of persons per house is about twice that in rural areas. All but a small proportion of housing is provided by private individuals, and the main role of the Ministry of Works and Housing is to supplement these efforts by handling standard government housing needs, developing a few housing estates in the large towns through the Housing Corporation, and piloting demonstration projects in such areas as low-cost housing and the development of suitable building materials. However, town planning procedures and human settlements policies are still largely outdated or inadequate.

Cultural life. *The cultural milieu.* Ghana has a rich indigenous culture. Culturally, the peoples of Ghana have many affinities with their French-speaking neighbours, but each tribal group has distinctive cultural attributes. In all parts of the country the cultural heritage is closely linked with religion and the institution of chieftaincy. Various festivals and rites are centred on chieftaincy and the family and are occasioned by such events as harvest, marriage, birth, puberty, and death.

Ghanaian society Ghanaian society is without sharp class distinctions. Insofar as traditional authority is based on a system of hereditary chieftaincy, it is possible to speak of aristocratic classes within the tribal groups, but the institution of chieftaincy is essentially democratic in operation and the authority of chiefs is broadly based. Land is usually owned by families, militating against the emergence of a small, powerful landed class wielding economic control over a landless class. These inherent egalitarian tendencies of the society have been heightened by economic and social mobility, depending on education and individual enterprise.

Daily life. Although the bonds of family life are an important factor in the social norms of Ghanaians as a whole, they tend to be much less pronounced among the urban population, where the trend is toward the nuclear family, especially among the professional classes and scattered immigrant groups.

The same differences between the urban and rural populations are found in dress and eating habits, with the urban dwellers being distinctly more Westernized and sophisticated. The national cuisine reflects the country's agricultural wealth and varied historical connections, and Ghana is one of the few countries in tropical Africa that can be said to possess a rich indigenous cuisine.

Traditional social values, such as respect for elders and

the veneration of dead ancestors, are generally more evident among the rural than the urban population. However, a revival in the importance of these values and a closer identity with traditional social roots, as expressed in the institution of chieftaincy, is gaining ground among the urban diaspora drawn from different parts of Ghana.

The arts. Ghana's arts include dance and music, plastic art (especially pottery and wood carving), gold- and silverwork, and textiles, most notably the richly coloured, handwoven *kente* cloth of the Akan and Ewe.

Indigenous art is in keen competition with various art forms of foreign origin, especially in those areas in which the end product is intended for practical household or personal use, such as pottery, carving, gold- and silversmithing, and weaving. Consequently, only the unique and most indispensable of these forms have managed to survive without special public support or patronage. The increased national self-consciousness generated in Ghana and in other African countries by the independence movement, however, has been instrumental in fostering and popularizing many art forms. An equally important factor has been the government's effort to promote tourism.

Literary and dramatic works

Of growing importance are literary and dramatic works produced by Ghanaian authors, although most of these are in English. Ghanaian works have attracted world attention in the fields of popular music, painting, sculpture, and film production. Important innovations in traditional dance have taken place since the mid-1960s, when the University of Ghana's Institute of African Studies embarked on the systematic study and organization of indigenous dance forms.

Cultural institutions. Apart from small groups of craftsmen who provide the chiefs' stools and skins throughout the country—a stool is the traditional symbol of office for chiefs in southern Ghana, and a skin is the equivalent symbol in the north—there are few established cultural institutions. The most outstanding are the National Cultural Centre, based in Kumasi, and the Arts Council of Ghana, based in Accra and with branches throughout the country. The National Cultural Centre is primarily concerned with the cultural heritage of Asante, while the Arts Council is concerned with the preservation of indigenous Ghanaian culture in all of its forms and with its development and improvement in light of contemporary local and world trends. Dance, music, drama, painting, and sculpture all come within the purview of the council. The Ghana Museum and Monuments Board is based in Accra. The board has an ethnological museum and a science museum in Accra and is responsible for the maintenance of buildings and relics of historical importance, such as the forts and castles, and for the preservation of important art treasures

throughout the country. The forts, built by various European powers, mostly between the 14th and 18th centuries, are all, except the Kumasi fort (1897), located on the coast.

For statistical data on the land and people of Ghana, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.   (E.A.B.)

HISTORY

Prehistoric era. As elsewhere in Africa, the climate of Ghana varied during the Pleistocene epoch. With greater rainfall, the forest spread northward and humans retreated toward the Sahara; when rainfall diminished, they occupied even the present forest. Apart from some pebble tools from high river terraces, the first industry is Late Chellean in the southeast. In the succeeding pluvial era, the Acheulean culture is lacking save from the extreme north.

With increases in aridity, humans reappeared, bringing Late Acheulean and Sangoan cultures, probably successively. They moved along the Togo mountain range from the Niger River. Sangoan tools abound in Transvolta and around Accra and extend to Kumasi; the west remained forest and was rarely visited. The Sangoan culture waned in the Gamblian pluvial era. At its close there appears a Lupemban culture, probably from the desiccating Sahara; it occurs in basal gravels of valleys carved during the preceding pluvial period. In central Ghana its tools are shapely, near the coast crude and formless.

Mesolithic traditions lingered into the succeeding subpluvial era. Thereafter excavations at Legon yielded quartz microliths made on small pebbles. Up-country these occur on silt terraces deposited in the preceding wet phase as far as the Niger. This culture is independent of the Saharan Mesolithic.

The latest Mesolithic period has stone hoes, quartz beads, and other Congo types; pottery seems absent. This stage dates to the post-Flandrian marine regression (end of 2nd millennium BC?).

Several Neolithic cultures seem identifiable. They contain polished axes and usually coarse pottery. The most distinctive appears around Kintampo and in the Accra plains; it had clay houses, Saharan chert microliths, shale arm rings, and scored terra-cottas like flattened cigars. A Neolithic culture more in Mesolithic tradition was excavated near Abetifi.

Neolithic cultures

Evidence is lacking for the introduction of iron. Polished stone was commonly used until the 16th century, especially in the forest. Trade in greenstone for ax manufacture flourished. In Transvolta and the west greenstone hoes are common. No satisfactory chronology has been established, nor can existing tribes be identified before the 17th century. Of excavated sites, Nsuta, with decorated pottery and bobbin beads, should be early medieval; the Sekondi village and cemetery, with fine pottery, stone axes, and quartz and shell beads, lasted until Portuguese times. In the north heavily decorated pottery continued later on open sites and mounds indicating clay houses. European imports are unknown before the 17th century. (O.D./Ed.)

Early traditions. The modern state of Ghana is named after the ancient African empire that flourished until the 13th century and was situated close to the Sahara in the western Sudan. The centre of ancient Ghana lay about 500 miles to the northwest of the nearest part of the modern state, and it is tolerably certain that no part of the latter lay within its borders. The claim that an appreciable proportion of modern Ghana's people derived from emigrants from the ancient empire cannot be substantiated with the evidence available at present. Written sources relate only to the period since European contact with the Gold Coast—*i.e.,* modern Ghana—began in the 15th century, or to Muslim contacts with ancient Ghana from about the 8th to the 13th century. Many modern Ghanaian peoples possess well-preserved oral traditions, but even though some of these may reach as far back as the 14th century, this is after the final disappearance of ancient Ghana, and such very early traditions often present considerable problems of interpretation. Little progress has so far been made in linking the surviving traditions with the available archaeological evidence.

Trade routes of Islām. More archaeological research,

especially into the Iron Age, will undoubtedly do much toward resolving present uncertainties about the early history of modern Ghana, but for the moment little more can be said than that the traditions of many of the states into which the country was divided before it came under British rule refer to their people having immigrated within the last 600 years either from the north or northwest or from the east or northeast. Such traditions link up with other evidence to suggest that the area which is now Ghana was for many centuries a meeting place for two great streams of western African history. Ultimately these streams stemmed from the existence of two major trans-Saharan routes, a western one linking the headwaters of the Niger and Sénégal rivers to Morocco and a more central one linking the region between the Niger Bend and Lake Chad with Tunisia and Tripoli. At the end of the western route arose the great Mande states, notably ancient Ghana and Mali, while around the more easterly termini developed Songhai, the Hausa states, and Bornu. There is evidence that parts of modern Ghana north of the forest were being reached by Mande traders (seeking gold dust) by the 14th century and by Hausa merchants (desiring kola nuts) by the 16th century. In this way the inhabitants of what is now Ghana were influenced by the new wealth and cross-fertilization of ideas that arose in the great empires of the western Sudan following the development of Islāmic civilization in northern Africa.

Migrations. It is against this background that the traditions of origin of the Ghanaian states must be viewed. It would seem that the first states of the Akan-speaking peoples who now inhabit most of the forest and coastlands were founded, in about the 13th century, by the settlement just north of the forest of migrants coming from the direction of Mande; that the dominant states of northern Ghana, Dagomba, Mamprussi, and their satellites were established by the 15th century by invaders from the Hausa region; that a little later the founders of the Ga and Ewe states of the southeast began to arrive from what is now Nigeria by a more southerly route; and that Gonja, in the centre, was created by Mande conquerors about the beginning of the 17th century.

Tradition tends to present these migrations as movements of whole peoples. In certain instances—for example, Dagomba, Mamprussi, and Gonja—it can be shown that the traditions relate in fact to comparatively small bands of invaders who used military and political techniques acquired farther north to impose their rule on already established populations whose own organization was based more on community of kin than on allegiance to political sovereigns. It is probable that the first Akan states—*e.g.,* such influential states as Bono and Banda north of the forest or the smaller states founded on the coast by migration down the Volta River—were also established in this way. The later Akan infiltration into the forest, which then was probably sparsely inhabited, and the Ga and Ewe settlement of the southeast may have been more of mass movements, though in the latter case it is known that the immigrants met and absorbed earlier inhabitants.

Contact with Europe and its effects. A revolution in Ghanaian history was initiated by the establishment of direct sea trade with Europe following the arrival on the coast of Portuguese mariners in 1471. Initially Europe's main interest in the country was as a source of gold, a commodity that was readily available at the coast in exchange for such European exports as cloth, hardware, beads, metals, spirits, arms, and ammunition. This gave rise to the name Gold Coast, by which the country was known until 1957. In an attempt to preserve a monopoly of the trade, the Portuguese initiated the practice of erecting stone fortresses (Elmina Castle dating from 1482 was the first) on the coast on sites leased from the native states. In the 17th century the Portuguese monopoly, already considerably eroded, gave way completely when traders from the Netherlands, England, Denmark, Sweden, and Prussia—Protestant seapowers antagonistic to Iberian imperial pretensions—discovered that the commercial relations developed with the Gold Coast states could be adapted to the export of slaves, then in rapidly increasing demand for the American plantations, as well as of gold. By the

mid-18th century the coastal scene was dominated by the presence of about 40 forts controlled by Dutch, British, or Danish merchants.

The presence of these permanent European bases on the coast had far-reaching consequences. The new centres of trade thus established were much more accessible than were the Sudanese emporia, and this, coupled with the greater capacity and efficiency of the sea-borne trade compared with the ancient overland routes, gradually brought about the reversal of the direction of the trade flow. The new wealth, tools and arms, techniques and ideas introduced through close contact with Europeans initiated political and social as well as economic changes. The states north of the forest, hitherto the wealthiest and most powerful, declined in the face of new combinations farther south. At the end of the 17th century the Akan state of Akwamu created an empire that, stretching from the central Gold Coast eastward to Dahomey, sought to control the trade roads to the coast of the whole eastern Gold Coast. The Akwamu empire was short-lived, but its example soon stimulated a union of the Asante states of the central forest, which union, after establishing its dominance over other neighbouring Akan states, expanded north of the forest to conquer Bono, Banda, Gonja, and Dagomba.

The Asante states

Having thus engrossed almost the whole of the area that served as a market and source of supply for the coastal trade, Asante turned toward the coastlands. There traditional ways of life were being increasingly modified by contact with Europeans and their trade, and when, beginning in the latter part of the 18th century, Asante armies began to invade the coastal states, their peoples tended to look for leadership and protection to the European traders in the forts. But between 1804 and 1814 the Danes, English, and Dutch had each in turn outlawed their slave trades, and the gold trade was declining. The political uncertainty following the Asante invasions impeded the development of new trades, and in these circumstances the mutually suspicious European interests were not always keen to embark on new political responsibilities. However, during 1830–44, under the outstanding leadership of George Maclean, the British merchants began to assume an informal protectorate over the Fanti states, much to the commercial benefit of both parties. As a result of this the British Colonial Office finally agreed to take over the British forts, and in 1850 it was able to buy out the Danes. However, trade declined under the new regime, which was averse to assuming formal control over the territory influenced from the forts, and in the 1860s, as a result of this influence and of the growth, from the 1820s onward, of Christian missionary education, the Fanti states attempted to organize a European-style confederacy. Further Asante incursions and the final evacuation of the coast by the Dutch (1872) combined to reverse this British policy, and in 1874 a punitive expedition sacked Kumasi, the Asante capital, and the Gold Coast was declared a British colony.

Colonial period. French and German activity in adjacent territories and the demand of British mining and commercial interests for better protection led to a further active period of British policy during 1895–1901, during which Asante was conquered and its northern hinterland formed into a British protectorate. The 56 years of British rule that followed went far toward welding into one state the three elements of the territory, the colonies of the Gold Coast and Asante and the protectorate of the Northern Territories, to which after World War I was added a fourth, under mandate from the League of Nations, the western part of former German Togoland. But this was hardly the result of deliberate policy. The ever increasing assimilation of European ways by the people on the Gold Coast had already made possible there the introduction of such organs of government as a legislative council (1850) and a supreme court (1853), but for many years Asante and the Northern Territories remained the sole responsibility of the governor, whose officials were from the 1920s onward encouraged to work with and through the authorities of the indigenous states. Attempts to introduce similar elements of indirect rule in the Gold Coast served mainly to stimulate a nationalist opposition among the educated professional classes, especially in the growing

towns, which aimed at converting the legislative council into a fully responsible parliament.

What really brought the country together was the great development of its economy following the rapid expansion of cocoa-growing by farmers in the forest. By the 1920s the Gold Coast, while continuing to export some gold, was producing more than half of the world's supply of cocoa; timber and manganese later became additional exports of note. With the wealth created by this great increase of trade, it was possible to provide modern transport facilities—harbours, railways, roads—and social services, especially education (to the university level), all of which tended to convert the traditional social order, groups bound together by kinship, into one in which individuals were linked principally by economic ties.

Independence. Political advancement tended to lag behind economic and social development, especially in the south. World War II and its aftermath tended to accentuate this lag, and in 1948 there were riots in the larger towns. An all-African committee under Justice (later Sir Henley) Coussey was appointed to work out a new constitution in which some executive power would be transferred to African ministers responsible to an African assembly. Meanwhile, a radical politician, Kwame Nkrumah, had established the Convention People's Party (CPP), which, with wide popular support, campaigned with strikes and other actions under the slogan "Self-government now." In 1951 the CPP won almost all the elective seats in the legislative assembly, whereupon Governor Sir Charles Arden-Clarke invited Nkrumah to lead the new administration. Power was rapidly transferred to an all-African cabinet responsible to a popularly elected national assembly.

In 1956 the trust territory of British Togoland chose by United Nations plebiscite to integrate with the Gold Coast. Securing more than 70 percent of the assembly seats at general elections in 1954 and 1956, Nkrumah and the CPP government were able in 1957 to obtain the recognition of their country, renamed Ghana, as an independent self-governing member of the Commonwealth and a member of the UN.

Nkrumah saw independent Ghana as a spearhead for the liberation of the rest of Africa from colonial rule and the establishment of a socialist African unity under his leadership. After the establishment of a republic in 1960, the state became identified with a single political party (the CPP), with Nkrumah, as life president of both, taking ever more power for himself. On the Pan-African front Nkrumah's messianism was increasingly challenged by other, often more stable, leaders of an ever-growing number of independent states. By 1966 his dream of African socialism was foundering under haphazard and corrupt administration, massive foreign debts, and declining living standards. In February, while he was in Peking, army and police leaders rose against him, and his regime was replaced by a National Liberation Council chaired by Lieutenant General Joseph A. Ankrah. The machinery of government was overhauled and conservative financial policies introduced. But Ankrah failed to restore parliamentary democracy, and in 1969 he gave way to the dynamic young brigadier Akwasi Amankwaa Afrifa, a principal leader of the coup. A constituent assembly produced a constitution for a second republic, and a general election was held in August 1969. This resulted in a substantial victory for the Progress Party, led by Kofi Busia, who became prime minister, and a year later a former chief justice, Edward Akufo-Addo, was chosen as president.

But the civilian regime, handicapped by the great burden of foreign debt it had inherited and the low price of cocoa on the world market, was slow to produce expected results. In January 1972 impatient army officers intervened again, and the government was taken over by a National Redemption Council (NRC) of military men chaired by Colonel Ignatius Kutu Acheampong. The national assembly was dissolved, public meetings prohibited, and political parties proscribed. In July 1972, a retroactive Subversion Decree was enacted under which military courts were empowered to impose the death penalty for offenses such as subversive political activity, robbery, theft, and damaging public property, and, from 1973, for the spreading of ru-

mours and profiteering. In 1975, the NRC was reorganized to include some civilians, but ultimate power was given to a Supreme Military Council.

In 1978, Acheampong (now a general) proposed a "Union Government to which everybody will belong," with no political parties and the military sharing in government with civilians. But a national referendum held to approve this served mainly to show the unpopularity of the NRC. He was replaced as chairman by Lieutenant General Frederick W.K. Akuffo, who had even less idea of what might be done than his somewhat more energetic predecessor. Eventually, in 1979, the government of the generals was overthrown by young officers and noncommissioned officers, led and inspired by an air force flight lieutenant, Jerry John Rawlings. Acheampong and Akuffo were executed, and a quick return to parliamentary government was organized. But under President Hilla Limann this failed to produce radical improvements in the political and economic life of Ghana. At the end of 1981, Rawlings decided that he and those who thought like him must take the lead in all walks of life. His second military coup established a Provisional National Defense Council as the supreme national government; at local levels, people's defense committees were to take the campaign for national renewal down to the grass roots.

Initially older Ghanaians doubted that Rawlings and his colleagues could provide more effective and less self-interested government than the old politicians or generals, while other young soldiers thought that they could themselves engineer coups to secure the fruits of power. But Rawlings easily snuffed out two countercoups in 1982 and 1983, and it was apparent that there was wide and genuine approval of his purpose of reforming Ghana's political and economic life. This continued even when he decided that there was no alternative but to follow conservative economic policies that would secure International Monetary Fund support and other foreign aid.

Rawlings kept his grip on political power through the 1980s and '90s, and this political stability enabled the adoption of economic and monetary reforms and attracted loans and investments from international agencies, Western governments, and private corporations. Inflation tapered off and the GDP began to rise. In 1992 a new constitution was approved by referendum and Rawlings was elected president. The Fourth Republic of Ghana was inaugurated on Jan. 7, 1993, and a new Parliament was invested, dominated by Rawling's party, the National Democratic Congress. Rawlings was reelected in 1996 but was barred from a third bid. In the 2000 elections, power was peacefully transferred to the New Patriotic Party's John Kufuor, the first such transfer since 1957.

For later developments in the history of Ghana, see the BRITANNICA BOOK OF THE YEAR.   (J.D.F.)

Guinea

The Republic of Guinea (République de Guinée) is an independent nation of western Africa. It is bordered by Guinea-Bissau, Senegal, and Mali to the north and east; by Côte d'Ivoire to the southeast; by Liberia and Sierra Leone to the south; and by the Atlantic Ocean to the west. Its area of 94,926 square miles (245,857 square kilometres) supports a largely rural population. The national capital of Conakry is the country's main port.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* There are four geographic regions: Lower Guinea, the Fouta Djallon, Upper Guinea, and the Forest Region. Lower Guinea includes the coast and coastal plain. The coast has undergone recent marine submergence and is marked by rias, or drowned river valleys, that form inlets and tidal estuaries. Numerous offshore islands are remnants of former hills.

Immediately inland the gently rolling coastal plain rises to the east, being broken by rocky spurs of the Fouta Djallon highlands in the north at Cape Verga and in the south at the Kaloum Peninsula. Between 30 and 50 miles (48 and 80 kilometres) wide, the plain is wider in the south than the north. Its base rocks of granite and gneiss (coarse-

grained rock containing bands of minerals) are covered with laterite (red soil with a high content of iron oxides and aluminum hydroxide) and sandstone gravel.

The Fouta Djallon highlands rise sharply from the coastal plain in a series of abrupt faults. More than 5,000 square miles of the highlands' total extent of 30,000 square miles lie above 3,000 feet (900 metres). Basically an enormous sandstone block, the Fouta Djallon consists of level plateaus broken by deeply incised valleys and dotted with sills and dikes, or exposed structures of ancient volcanism resulting in resistant landforms of igneous rock, such as the Kakoulima Massif, which attains 3,273 feet northeast of Conakry. The highest point in the highlands, Mount Loura, rises to 4,970 feet (1,515 metres) near the town of Mali in the north.

Upper Guinea is composed of the Niger Plains, which slope northeastward toward the Sahara. The flat relief is broken by rounded granite hills and outliers of the Fouta Djallon. Composed of granite, gneiss, schist (crystalline rock), and quartzite, the region has an average elevation of about 1,000 feet.

The Forest Region, or Guinea Highlands, is a historically isolated area of hills in the country's southeastern corner. Mount Nimba (5,748 feet; 1,752 metres), the highest mountain in the region, is located at the borders of Guinea, Liberia, and Côte d'Ivoire. The rocks of this region are of the same composition as those of Upper Guinea.

Drainage and soils. The Fouta Djallon is the source of western Africa's three major rivers. The Niger River and several tributaries, including the Tinkisso, Milo, and Sankarani, rise in the highlands and flow in a general northeasterly direction across Upper Guinea to Mali. The Bafing and Bakoy rivers, headwaters of the Sénégal River, flow northward into Mali before uniting to form the main river. The Gambia River flows northwestward before crossing Senegal and The Gambia.

The Fouta Djallon also gives rise to numerous smaller rivers, such as the Fatala, Konkouré, and Kolenté, which flow westward across the coastal plain to enter the Atlantic. The Forest Region generally drains to the southwest through Sierra Leone and Liberia. The St. Paul River enters the Atlantic at Monrovia, Liberia, and the Moa River has its mouth at Sulima, Sierra Leone.

The most common soils are laterites formed of iron and hydrated aluminum oxides and other materials that often concretize into hard iron-rich conglomerates. In the northeast, sandy brown soils predominate, while along the coast black, heavy clay soils accumulate in the backwaters. There are alluvial soils along the major rivers. Soil conservation is extremely important because most soils are thin, and the heavy rainfall causes much erosion.

Climate. The climate of Guinea is tropical with two alternating seasons—a dry season (November through March) and a wet season (April through October). The arrival of the migratory intertropical convergence zone (ITCZ) in June brings the heaviest rainfall of the wet season. As the ITCZ shifts southward in November, the hot, dry wind known as the harmattan blows from the northeast off the Sahara.

On the coast a period of six months of dry weather is followed by six months of rain. The average rainfall at Conakry is 170 inches (4,300 millimetres) a year, and the average annual temperature is about 81° F (27° C). In the Fouta Djallon, January afternoon temperatures range between 86° and 95° F (30° and 35° C), while evening temperatures dip to 50° F (10° C). Rainfall varies between 63 and 91 inches annually, and the average annual temperature is about 77° F (25° C).

In Upper Guinea rainfall drops to about 59 inches a year. During the dry season temperatures of more than 104° F (40° C) are common in the northeast. In the Forest Region at Macenta, there may be 106 inches of rain annually. Only the months of December, January, and February are relatively dry, each having less than one inch of precipitation. At low altitudes, temperatures resemble those of the coastal areas.

Plant and animal life. The coast is fringed with mangrove trees, and the coastal plain supports stands of oil palms. The Fouta Djallon is mostly open, with trees grow-

ing along the wider stream valleys. In Upper Guinea, the savanna grassland comprises several species of tall grasses that reach heights of five to 10 feet during the rainy season. Deciduous trees grow in scattered clumps, but few have commercial value; baobabs and shea trees furnish fruit and oil. The Forest Region contains several extensive patches of rain forest, with teak, mahogany, and ebony trees; agriculture, however, has diminished the forests and resulted in a shift largely toward open savanna.

Guinea is not rich in African big game. Baboons and hyenas are common, while an occasional wild boar, several types of antelope, and a rare leopard may be sighted. A few hippopotamuses and manatees inhabit the rivers of both Lower and Upper Guinea. Poisonous snakes include mambas, vipers, and cobras, along with pythons and a variety of harmless snakes. Crocodiles and several varieties of fish are found in most rivers.

Settlement patterns. Until recent urbanization and movement toward regional towns, the Fulani (Fulbe, Fula, or Peul) of the Fouta Djallon tended to live in small hillside hamlets of 75 to 95 persons each, with the lower classes occupying the valleys. In the heart of the highlands the countryside was thickly settled with hamlets every few miles, while in the east the land was less settled. In Lower Guinea, villages were grouped together at the bases of hills, in the open plain, or in a valley floor. Village solidarity was more marked in this area than in the highlands, and each village contained between 100 and 200 people.

The majority of the Malinke (Mandingo) people of Upper Guinea lived in moderately large villages of about 1,000 inhabitants located near permanent water sources, the adjacent soils of which were used for cultivation. The villages were tightly grouped; there were empty brush areas in which farming was unprofitable.

In the Forest Region the effects of human occupation, especially in the southwest, have become apparent only since the mid-20th century. Among the Kissi people on the Sierra Leone and Liberian borders, rice was grown on most hillsides and in every low-lying and swampy area. Villages tended to be small and rarely contained more than 150 people; they were often tucked inside groves of kola, mango, and coffee trees. Farther east among the Loma and Kpelle people, fire-cleared land was used to plant vegetables and rice. Larger villages were usually located on remote hillside terraces that are often surrounded by secondary forest growth.

Guinea's main urban centre is Conakry. The old city, located on Tumbo Island, retains the segregated aspect of a colonial town, while the Camayenne (Kaloum) Peninsula community, which has grown up since the 1950s, has a few buildings of the colonial period. From the tip of the peninsula, an industrial zone has a growing salaried population that is truly urbanized.

The second largest town, Kankan, in Upper Guinea, is a commercial, educational, administrative, and Muslim religious centre of some importance. Labé, located well into the Fouta Djallon, serves as a market town and an administrative and educational centre. Nzérékoré, in the Forest Region, serves the same functions as Labé. Other important towns are the trading centres of Kindia and Mamou and the industrial settlements of Boké, Fria, and Kamsar.

The people. *Ethnic and linguistic composition.* The four major geographic regions largely correspond to the areas inhabited by the major linguistic groups. In Lower Guinea the major language of Susu has gradually replaced many of the other indigenous languages and is a lingua franca for most of the coastal population. In the Fouta Djallon the major language is Pular (a dialect of Fulfulde, the language of the Fulani), while in Upper Guinea the Malinke (Maninkakan) language is the most widespread. The Forest Region contains the linguistic areas, from east to west, of Kpelle (Guerzé), Loma (Toma), and Kissi.

Besides the diplomatic community and a growing number of expatriate teachers and technical advisers, the number of non-Guinean residents has increased considerably since 1984. This community includes Lebanese and Syrian traders and a growing number of French engaged in agriculture, business, and technical occupations.

Religions. Nearly three-quarters of the population is

Marginal notes:

Vanishing animal life

Guinea's urban centres

Muslim, and a small but influential percentage is Christian, mostly Roman Catholic. A substantial minority of Guineans continue to follow local traditional religious practices.

Demographic trends. Life expectancy has improved only slightly since independence and, at 39 years for men and 42 years for women, ranks as one of the lowest in sub-Saharan Africa.

Immigration increased slightly after 1984, and emigration, which was high in the 1970s and early 1980s—especially from the Fouta Djallon and Upper Guinea—decreased in the 1980s. At its peak this out-migration consisted of one-sixth of the working-age male population, leaving an imbalance of aged, children, and women. Emigration was directed toward the neighbouring countries, with a small percentage going to Europe or North America.

The heaviest regional population concentration is in the Fouta Djallon. Conakry, the Camayenne Peninsula, and, to a lesser extent, the industrial enclaves of Boké, Fria, and Kamsar suffer from rapid population growth caused primarily by continuing migration from the rural areas to the urban centres. Except for the Fouta Djallon, population poses no serious immediate threat to development because there is no pressure on the land and no landholding class.

The economy. Agriculture and other rural activities account for 80 percent of the country's employment, with less than 10 percent in industrial employment (including mining). The rest of the wage and salary earners are in the service and governmental sectors. In general, salaries are low, and the need for extra-salary means in order to eke out a livelihood remains the norm.

The shortage of trained personnel is serious, and finances suffer from misappropriation and tax evasion. Many of the processing industries have been held back by inadequate supplies of raw materials. Internal production is not sufficiently high, in agriculture particularly, and the shortage of investment capital is persistent.

Resources. Guinea has from one-third to one-half of the world's known reserves of bauxite, plus significant reserves of high-grade iron ore at Mount Nimba and the Simandou Mountains. Alluvial gold is taken from the Niger and its tributaries, and diamond production is substantial and largely of gem-quality stones. The southeastern rain forest has some valuable species of tropical hardwoods, and both river and ocean fisheries yield large catches of food fish. Hydroelectric potential is considerable because of the high rainfall and deep gorges of the Fouta Djallon but has been only partially developed, largely to meet the demands of the alumina sector.

Agriculture, forestry, and fishing. Guinea is an agricultural nation. The high plateaus of the Fouta Djallon are little more than part-time pastures, with hillsides given over to the growing of peanuts (groundnuts) and fonio (a sorghumlike grain). Along the streams and rivers, rice, bananas, tomatoes, strawberries, and citrus fruits are grown commercially. Most families have truck gardens, and tsetse-resistant Ndama cattle, sheep, goats, horses, donkeys, chickens, and Muscovy ducks are raised.

In Lower Guinea, oil and coconut palms, rice, bananas, vegetables, salt, and fish are important elements of trade. A number of large-scale plantations produce a good quantity of bananas and pineapples. Except for poultry and a few goats, there are relatively few domestic animals. In Upper Guinea, grains and cassava (manioc) are important food crops; vegetables, tobacco, and karite (shea butter) are traded locally; and domestic animals are common.

In the Forest Region, rice is the chief food crop, along with cassava, peanuts, and corn (maize). Gardens of tomatoes, peppers, eggplants, and tobacco are scattered in the shade of fruit trees, and coffee trees, kola nuts, and oil palms are important cash crops. Goats and fowl are the most common domestic animals.

Experiments conducted in the early 1970s with large-scale cooperative agricultural production were unsuccessful. Relatively low government farm prices and the high cost and scarcity of consumer goods caused many producers to return to subsistence agriculture or to resort to smuggling. The production of coffee, formerly the major cash crop, declined. Food imports of staples such as rice, once exported, remain necessary. The production of other cash crops, such as palm kernels, peanuts, pineapples, bananas, and citrus fruit, has improved only marginally since 1984, though considerable potential for expansion exists.

Commercial fishing continues to grow with the introduction of U.S., French, Japanese, and other internationally financed and operated fishing ventures. Individual small-scale riverine and marine fishing, producing fresh, dried, and smoked fish for local markets, remains important.

Forestry is hampered by the lack of adequate transportation. Mixed government and private-investment sawmills and plywood plants function below capacity because of insufficient supplies of timber, transportation difficulties, and inadequate capital and managerial input.

Industry. Guinea depends heavily upon mineral exports to maintain a favourable trade balance. The bauxite deposits at Fria, Kindia, and Sangaredi in the Boké region are exploited by international consortia in which the Guinea government holds major shares. Similarly mixed foreign and domestic plants produce the bauxite and alumina that provide nine-tenths of Guinea's export earnings.

The iron-ore deposits of Mount Nimba are exploited under a shipping agreement with the government of Liberia. Mining of gem-quality diamonds has increased greatly since 1984, and gold production has risen substantially as well.

Food-processing plants run at less than full capacity because agricultural production is insufficient and capital and managerial input are inadequate. Most industry consists of the manufacturing of light consumer goods and the primary processing of agricultural products. Heavy industry and manufacturing is not part of the economic planning for Guinea.

Finance. Since 1984 the government of Guinea has pursued a slow process of economic reform aimed at reestablishing a free-market system. In 1986 Guinea began a process to link its currency with the French franc again after having maintained a nonconvertible currency since 1960. The government has also actively sought closer economic ties with France and other Western nations.

In mid-1985 a new banking law was passed allowing the establishment of new commercial banks to replace the publicly owned institutions (with the exception of an Islamic bank established in 1983) that had existed under the Touré government. In December 1985 three new banks involving French participation began operation. They are the Banque Internationale pour l'Afrique en Guinée (BIAG), the Banque Internationale pour le Commerce et l'Industrie de la Guinée (BICI-GUI), and the Société Générale de Banques en Guinée (SGBG). The central bank is the Banque Centrale de la République de Guinée.

The Guinean investment code follows fairly classical lines, offering a variety of inducements to domestic and international investors in productive sectors. Benefits include waivers of import duties on capital equipment and deductions of various peripheral tax liabilities such as statutory employers' contributions. Compared with many other African nations, the extent of these investor benefits is modest.

Government revenue is derived chiefly from mining concessions, import and export duties, excise taxes, a petroleum-products tax, and taxes on commercial transactions and production. There are also various other surtaxes, stamp duties, and registration fees. Business and other licenses and personal-property, building, dwelling, and vehicle taxes are handled by the prefecture administrations. Taxes on salaries and wages contribute little revenue because few people are salaried and because many wage earners work within the government.

Trade. Trade figures are limited and sketchy. During the Touré regime smuggling of both imports and exports brought on by an unrealistic exchange rate and poor returns to agricultural producers selling in the domestic market made accurate trade figures impossible. Estimates prepared by the World Bank show that, while Guinea recorded a substantial surplus on visible trade in the 1980s, its export base was narrow and largely dependent on the mining industry for international trade earnings.

Marginal notes:

Bauxite and diamonds

Mining and quarrying

Exports of gold and diamonds, in particular, have shown substantial growth since 1984.

Among the principal markets for Guinean bauxite and alumina are France and the United States, while France is the largest supplier of imports. A growing balance of payments deficit has characterized the economy in spite of merchandise surpluses in the 1980s. With virtually no private capital inflow, the government has been forced to simply fall behind in debt service payments and make stringent cutbacks in both investments and the yearly operating budget.

Transportation. Guinea's transportation system is largely based upon the road and railway from Conakry to Kankan. This forked axis is intersected at Mamou by a road north to Senegal. East of Kouroussa the road branches northeastward through Siguiri to Bamako, Mali. The main road continues northeast of the railhead at Kankan to Sikasso, Mali. The regional centres, like pods strung out on a vine, lie along thin lines of communication that, in turn, radiate feeder routes.

The railroad from Conakry to Kankan is a single-track metric line. Two other railways serve the bauxite mining areas, including a line linking Conakry to the Fria bauxite mines. The Boké Railway runs between Kamsar and Sangaredi.

The port facilities of Conakry are extensive. There is a channel 26 to 66 feet deep and dock space with modern loading equipment. The Sangaredi bauxite mine company maintains its own ore-exporting port at Kamsar. Coastal shipping, however, is limited.

The Gbessia international airport at Conakry serves jets of all sizes. Air Guinée operates a somewhat irregular schedule of weekly domestic flights to the hard-surfaced airports at Kankan, Labé, and Faranah and maintains occasional service to Bamako, Mali; Dakar, Senegal; Freetown, Sierra Leone; Monrovia, Liberia; and several small, unsurfaced domestic landing strips.

Administration and social conditions. *Government.* For more than 25 years under President Sékou Touré, Guinea was a one-party state ruled by the Democratic Party of Guinea (PDG). In April 1984, after Touré's death, a military group abolished the PDG and all associated revolutionary committees and replaced them with the Military Committee for National Recovery (CMRN). A new constitution in 1991 began a transition to civilian rule. Political parties were legalized in 1992, and Guinea's first multiparty elections were held in 1993. The constitution provides for a civilian president and a unicameral legislature, both elected by universal suffrage.

The CMRN

Education. The government has put a major emphasis on improving the provision of education. In the early 1980s only about one-quarter of primary-school-age children were enrolled in school. Educational facilities at all levels had shown a marked decline in the last decade of the Touré government. Despite improvements, perhaps three-quarters of the population is illiterate in French, and the overall adult literacy rate is below average for western Africa.

Primary education is compulsory for six years beginning at age seven. Secondary education is also offered as a six-year program. Instruction is offered in French and in local languages. Private schools, previously banned, were allowed to reopen in 1984.

The country's post-secondary institutions, particularly the University of Conakry, function on an irregular basis, with assistance from France and other countries for personnel and materials.

Health and welfare. Since independence the government has made an effort to improve health care services, but infant and child mortality rates remain among the highest in sub-Saharan Africa. Equipment and supply shortages and an inadequate number of medical personnel hamper the health care system. Government-run infant clinics and child-care centres are inadequate. Most such social welfare services are either provided by the extended family or are absent.

A severe housing shortage exists in the urbanized areas, though mud and straw construction reduces the problem in rural areas. It is estimated that one-fifth of the country's population lives in Conakry and its environs, where the housing shortage is especially serious.

Cultural life. Until 1984 artistic and literary expressions were limited largely to African themes by the single political party and its leader. As a result Guinean intellectuals exhibit a strong sense of nationalism and a decolonialized state of mind. As greater openness of expression returns, a distinctly Guinean literature is gradually emerging.

A truly autonomous free press has yet to emerge as a major force in Guinean life. One French-language newspaper, *Horoya,* formerly controlled by the PDG, is published. A number of informal newsletters are also published in indigenous languages. A television service was begun in 1977, and transmissions continue on an irregular basis for short periods each day.

Press and broadcasting

The telephone network is limited and obsolescent; the few telephones in service are almost all in Conakry and other major urban centres. A program to upgrade the telecommunications system was implemented in the late 1980s.

The professional National Guinean Ballet, which emerged after independence, has retained some of the dance and music of the distinct ethnic and regional groups. Creative accomplishments in modern dance and popular music have given Guinean musicians and singers an international reputation.

Handicrafts in Guinea, as elsewhere in Africa, declined sharply during the colonial era with competition from manufactured consumer goods. The lack of tourism and creative marketing since independence has limited the amount of change and innovation in local crafts, so that the leatherwork, wood carving, and jewelry produced in Guinea tend to be more genuinely ethnic than elsewhere in western Africa.

For statistical data on the land and people of Guinea, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

Early history. Hunting and gathering populations occupied the area of Guinea at least 30,000 years ago, and farming has been practiced there for about 3,000 years. About 1,000 years ago Susu and Malinke (Maninka) people began to encroach on the Baga, Koniagi (Coniagui), and Nalu (Nalou) populations who had been living in the area for more than 1,000 years. The towns and villages of Upper Guinea were incorporated into the Mali empire from the mid-13th century, and by the 16th century the Fulani (Fulbe) had established domination over the Fouta Djallon.

The Portuguese presence on the coast dates from the 15th century, and the slave trade continued to affect Guinea until the mid-19th century. British and French trading interests on the coast played minor roles in the historical evolution of the Guinean interior until the *almamy* (ruler) of Fouta Djallon placed his country under French protection in 1881. The independent Malinke state ruled by Samory Touré resisted the French military until 1898, and isolated small groups of Africans continued to resist the French until the end of World War I.

Colonial era. The French protectorate of Rivières du Sud was detached from Senegal as a separate colony in 1890. As French Guinea it became part of the Federation of French West Africa in 1895. Treaties with Liberia and Great Britain largely established the present boundaries by World War I.

Under the 1946 constitution of the French Fourth Republic a small number of French-educated Africans in Guinea were allowed to vote for deputies to the French National Assembly. In the 1958 referendum on the constitution for the French Fifth Republic only Guinea, under the influence of Sékou Touré, who later became the country's first president, voted against membership in the French Community and became independent.

Independence. Guinea came to occupy a special position among African states for its unqualified rejection of neocolonial control. Touré's rule grew increasingly more repressive, however. Denied French assistance, Guinea contracted loans and economic and trade agreements with

the former Soviet Union and the People's Republic of China. When it failed to become a full economic partner in the Soviet bloc, Guinea turned to France and the West for capital and technical assistance in the waning years of Touré's regime. Under uncertain economic leadership, however, the potentially wealthy country did not prosper.

Throughout Touré's rule, difficulties of economic adjustment and political reorganization caused him to become increasingly obsessed with what he perceived as opposition. Probably the event that had the most negative effect was the Portuguese-backed invasion of Conakry by Guinean dissidents. Such real conspiracies, together with a myriad of imaginary ones, led to show trials, imprisonments, and executions of dissidents and other suspects. Gradually power was concentrated in the hands of Touré and his predominantly Malinke associates. Members of his own family occupied leading government posts, from which illicit earnings were drawn on a large scale. Though the Democratic Party of Guinea (PDG), which Touré had led since 1953, retained control, it ceased to enjoy the mass support it had had in the late 1950s and early 1960s. Touré's death in 1984 left party leaders with little grassroots support. The ensuing military coup began with fairly strong support from the general public.   (T.E.O'T.)

The Military Committee for National Recovery under Colonel Lansana Conté, Guinea's second president, endorsed the concept of a pluralist society. Private ownership and international investment were actively supported, while the role of the state in the economy was reduced. In the late 1980s Guinea sought reintegration into French-speaking western Africa and the Franc Zone. The Conté government's move toward political and economic liberalization was slow, however, and civil unrest and protest continued during the 1990s. In 1996 the government survived an attempted military coup. Despite ongoing turbulence, Conté maintained power into the early 21st century.   (Ed.)

For later developments in the history of Guinea, see the BRITANNICA BOOK OF THE YEAR.

Guinea-Bissau

The Republic of Guinea-Bissau (República da Guiné-Bissau) became an independent nation on Sept. 10, 1974, after more than a decade of war. The country is bounded by Senegal to the north, by Guinea to the east and south, and by the Atlantic Ocean to the west. Including the Bijagós (Bissagos) Archipelago and other islands lying off the coast, the total area is 13,948 square miles (36,125 square kilometres). The capital is Bissau.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Almost all of Guinea-Bissau is low-lying and is bathed daily by tidal waters that reach as much as 62 miles (100 kilometres) inland. In the southeastern part of the country, the Fouta Djallon plateau rises approximately 600 feet (180 metres). The Boé Hills extend from the western slopes of the Fouta Djallon to the Corubal Basin and the Gabú Plain.

Drainage   The coastal area is demarcated by a dense network of drowned valleys, called rias. The Bafatá Plateau is drained by the Geba and Corubal rivers. The Gabú Plain occupies the northeastern portion of the country and is drained by the Cacheu and Geba rivers and their tributaries. The interior plains are part of the southern edge of the Sénégal River basin. The uniform elevation of the mature floodplain allows rivers to meander and renders the area susceptible to flooding during the rainy season.

Climate. Rainfall occurs between May and October, followed by a dry season. April and May are the hottest months, with afternoon temperatures in the high 90s F (mid-30s C) at most locations. The coast has a monsoonal climate with abundant rainfall, amounting to 60 to 120 inches (1,500 to 3,000 millimetres), whereas the interior is influenced by the tropical savanna climate, with greater variation in rainfall and temperature.

Plant and animal life. The three zones of vegetation are the coastal swamps and plains that are covered with mangrove and palm trees, the heavily forested interior plain, and the savanna found in the north.

Guinea-Bissau has a great variety of aquatic birds, including pelicans and flamingos. Crocodiles, snakes, gazelles, apes, parrots, hyenas, and leopards abound.

Settlement patterns. The large majority of Guineans live in villages. In general, the ecology places severe limitations on agriculture, but Guineans have adapted to the environment in a number of complex ways. At least 19 microecologies have been identified with as many farming systems, the common feature being rice cultivation. Coastal areas specialize in saltwater varieties grown in flooded paddies.

The Balanta Brassa, who occupy the central and southern parts of the country, are renowned as paddy rice growers. Another coastal people, the Bram (Brame), are known for their skill in farming without irrigation. The Bijagós people and the Mandyako (Manjaco) specialize in processing palm wine and palm oil, while inland Fulani (Fula) raise cattle. Fulani and Malinke (Mandinga) grow the largest volumes of peanuts (groundnuts) and cotton. Almost all peoples farm a variety of terrains, growing a number of different kinds of produce and using multicropping techniques to ensure one or more successful crops.

© Dave G. Houser

Villagers pounding rice, Bijagós Islands, Guinea-Bissau.

The war of independence against Portugal (1963–74) uprooted many peoples. Some estimate that fully half the population was affected. The Portuguese disrupted production by superimposing a form of temporary settlement—the "strategic hamlet"—to isolate as many people as possible from the nationalist forces. In the nationalist-held territories, regroupings also took place in the forests to escape air attacks from the Portuguese. More than 100,000 people fled to Senegal or Guinea to escape the war.

The people. *Ethnic and linguistic composition.* The population includes more than 20 ethnicities; the main groups are the Balanta, Fulani, Mandyako, Pepel (Papel), Bram, and Malinke. In theory, each ethnic group originally had a territory (known as *chao*), but conquest—first by the Malinke and then by the Fulani and their expansion toward the coast—the movement of the Balanta southward, and the war and postwar migrations have tended to complicate the settlement pattern.

The largest and most widely spread group, the Balanta Brassa, belong to a relatively egalitarian society in which patrilineage, household, age group, and gender are important divisions. They were the most receptive to nationalist slogans of emancipation from Portuguese rule. A fiercely independent people, largely animist in belief, they constituted the most notable body of guerrilla forces during the war against Portugal. A recent grassroots movement sought renovation and change in the social structure.

The Balanta Brassa

The Fulani, who may be divided into at least three subgroups, were originally pastoralists, but in the 19th century they conquered large sections of western Africa. Their society is Muslim and hierarchical. Largely impervious to Portuguese culture—but not to collaborating with the colonial administration—many of their leaders became tactical allies of the Portuguese army against the guerrillas, whom they saw as a threat to their religion, society, and traditions. Some smaller groups, however, joined the nationalists in order to emancipate themselves from the authority of elders and lords.

The Malinke, the ancient rulers of the Senegambia, live in stratified societies of noble families; craftsmen, traders, and other professional groups; and descendants of former captives. They also converted to Islām.

Mandyako and Pepel in the northern coastal region were among the first peoples to establish trading relations with the Portuguese. Some intermarried with them; others worked for them, adopting European customs and dress and helping to create and spread the trading language Crioulo. The Pepel, however, fiercely defended their landlord rights against the Europeans. Some of the smaller groups, such as the Biafada, Felupe, Bayot, Nalu, Susu, and Bijagós, are coastal farmers and appear to have been little influenced by either Portuguese or Islāmic culture.

Urbanized Guineans, formerly called *assimilados* and numbering only a few thousand, adapted many aspects of European culture and became chiefly civil servants or white-collar workers, professions they still occupy. A formerly significant colony of Cape Verdeans immigrated during colonial times as farmer-traders, soldiers, and administrators for the Portuguese. They played a prominent role within the nationalist leadership, seeking to unite Cape Verde and Guinea-Bissau, but lost most of their influence after the coup in 1980. Non-Africans include Portuguese, eastern and western European, Cuban, and Brazilian technical experts and Lebanese merchants.

Among the African languages spoken are two categories: the first includes the Mande-tan grouping and the Mandefu grouping. The second, the Atlantic (West Atlantic) language group, includes all other African languages spoken in Guinea-Bissau. Apart from this mixture of some 20 languages and dialects, the lingua franca is Crioulo. It exerts a unifying influence in the rural areas and, along with Portuguese, is used in schools. Portuguese is the official language. Some Arabic is known by Muslim scholars.

Religions. Traditional animist beliefs have remained strong, even among those who have formally adopted Christianity or Islām. Christianity made only a few inroads during the Portuguese colonial period. There remain a small number of Roman Catholics and even fewer Protestants.

Role of Islām

Most adherents of Islām belong to the Qādirīyah or Tijānīyah orders. Portugal supported the expansion of Islām to help counteract the influence of nationalist leaders. Since independence, the government of Guinea-Bissau has joined the Islāmic Conference and receives aid from Saudi Arabia and Kuwait. The Libyan government, moreover, supports the spread of Islām in a variety of ways.

Demographic trends. The population is growing at a comparatively moderate rate for sub-Saharan Africa. It is young, with about two-fifths of Guineans less than 15 years of age, portending a higher rate of growth in the near future. The average life expectancy is low, owing largely to a high infant mortality rate. Nearly half the population is active in the work force; only about one-third is urban. There is a significant seasonal and permanent migration.

(R.P./R.E.Ga.)

The economy. *Resources.* There are large deposits of bauxite in the east along the Guinean border, and phosphates in the centre and northwest have been found. A lack of infrastructure has slowed mining. There is offshore prospecting for petroleum. The Corubal River has immense hydroelectric potential, and a project is planned on the Corubal at Saltinho.

Agriculture, fishing, and forestry. The economy is largely agricultural, with good prospects for forestry and fishery development. Rice is the main staple, and export crops include cashews, palm products, timber, and seafood. Indigenous hardwoods are the predominant forestry export. Most of the fishing is done by foreign vessels under license.

Restoration of prewar levels of production has been hampered by government neglect of rural development and by trade policies that primarily benefit urban areas. Less than half the arable land is in use. Urban areas in particular have suffered food shortages, and scarce foreign exchange is used to import food.

Industry. The amount of industry is small. Most factories produce light consumer goods.

Finance and trade. Guinea-Bissau is a member of the West African Economic and Monetary Union (Union Économique et Monétaire Ouest Africaine; UEMOA), a regional common market formed in 1994. The monetary unit for the country is the CFA (Communauté Financière Africaine) franc, issued by the Central Bank of West African States. There is also a government-owned savings and loan institution, a postal savings bank, and a partly Portuguese-owned commercial bank.

Exports average about one-third the value of imports and consist primarily of agricultural products (principally cashews) and wood products; they are shipped mostly to India, Thailand, Portugal, Senegal, and France. Imports consist principally of foodstuffs, petroleum products, construction materials, and machinery and are obtained mainly from Portugal, Senegal, India, and China.

Transportation. River transport accounts for most of the commerce in the south, whereas northern and eastern areas are served mainly by roads. Both networks centre on Bissau and need upgrading. There are few paved roads and no rail lines. Bissau is the only port for oceangoing vessels, but several other coastal and river ports are regularly served by barges. The airport at Bissalanca (near Bissau) handles international air traffic, while several smaller airports and landing strips serve the interior.

Administration and social conditions. *Government.* Guinea-Bissau is a republic. Executive power is vested in the president, who serves as the chief of state; the prime minister, who serves as the head of government; and the Council of Ministers. The president is popularly elected to serve a five-year term and appoints the prime minister. The legislative branch of government consists of the unicameral National People's Assembly; members are popularly elected to four-year terms. The judicial system comprises the Supreme Court, Regional Courts, and Sectoral Courts. For administrative purposes, Guinea-Bissau is divided into eight *regiões* (regions) and the autonomous sector of Bissau; the regions are further divided into *sectores* (sectors).

Local administration

Guinea-Bissau became a multiparty state in 1991. It had previously been a single-party state, led since independence by the African Party for the Independence of Guinea and Cape Verde (PAIGC). In addition to the PAIGC, other political parties active in the country include the Party for Social Renovation (PRS), the United Social Democratic Party (PUSD), the Electoral Union (UE), and the United Popular Alliance (APU).

Education. The government provides six years of compulsory education. For those children who show scholastic promise there are five years of secondary education. Amílcar Cabral University and the University of Colinas de Boe, both founded in 2003 and based in Bissau, provide opportunities for higher education. There are also schools for teacher training, nursing, and vocational training. Only some two-fifths of school-age children attend school, however, and adult illiteracy remains high.

Health and welfare. The state of health in Guinea-Bissau is poor. The health care system aims at providing basic medical care for all citizens and is engaged in training health workers in every village. The goal is a health post in each section, a sectoral referral system, and a regional hospital within the reach of every citizen. There are two national hospitals and one centre for psychiatric care in Bissau. The financing of the health care system is heavily dependent upon foreign assistance.

Cultural life. Cultural life in Guinea-Bissau is mainly organized by the government. There is a state radio station and an experimental television service. The government

publishes its own newspaper, *Nô Pintcha*. The National In-
stitute of Studies and Research (INEP) sponsors social and
scientific investigation. The national arts institute main-
tains a school of music and dance. There is a public library
and museum.   (R.E.Ga./Ed.)

For statistical data on the land and people of Guinea-
Bissau, see the *Britannica World Data* section in the
BRITANNICA BOOK OF THE YEAR.

HISTORY

Early history. For more than a thousand years the coast
of Guinea-Bissau has been occupied by iron-using agricul-
turists. They were particularly skilled in the production of
irrigated and dry rice and were suppliers of marine salt to
adjacent areas of the western Sudan. From the 13th centu-
ry, coastal farmers came increasingly into contact with the
outside world, first landward, then later from the sea. The
earliest recorded influences are associated with the dissolu-
tion of the Ghana empire when displaced peoples sought
refuge near the coast. Later the region was drawn into the
sphere of the Mali empire, and regional governors called
*farim*s were appointed to impose some form of allegiance
to the great Mande ruler.

Portuguese   Overseas contacts with the Guinea Coast were opened by
contact   the Portuguese, starting in the 1440s. Guinea played an
important role in the colonization of the Cape Verde is-
lands from this period. Slave labour was first used to es-
tablish plantations of cotton and indigo, and then skilled
Guinea craftsmen were introduced to establish a weaving
and dyeing industry. Much of the cloth was sent back to
the mainland for the purchase of slaves destined for the
Americas. The transatlantic slave trade was facilitated by
the Portuguese and *lançados* (people of mixed descent)
who acted as intermediaries between the Guinean rulers
and the visiting slave ships. In the 16th century the expan-
sion of Mande-speaking peoples into the upper Guinea
Coast area caused wars that swelled the number of prison-
ers available for export as slaves. Trade was also conduct-
ed in salt, kola nuts, and food to the interior and ivory,
wax, dyewood, and hides overseas, mainly to Portugal,
Britain, Holland, and France.

During the next four centuries, when the slave trade was
the main economic activity of the country, the people of
Guinea had little difficulty in preventing or restricting the
attempts of foreign powers to establish territorial claims. A
post established at Cacheu by Cape Verde traders in 1588
was supported by the Lisbon government during the 17th
century but did not expand. In 1687 a Portuguese post was
established at Bissau to try to limit French commercial
competition but failed to survive, and in 1792 the English
briefly held a settlement at Bolama. Meanwhile, the Por-
tuguese had reestablished a base at Bissau and during the
19th century increasingly came to regard the coast on ei-
ther side as sovereign territory.

The colonial era. The Portuguese territorial claim in
Guinea was disputed by both the British and the French.
Negotiation first excluded the British (1870) and then set-
tled the boundaries with the French-claimed territories
(1886 and 1902–05). These agreements were followed by
the slow, sometimes violent imposition of Portuguese colo-
nial rule. The final "pacification" campaigns, fought by
João Teixeira Pinto in 1913–15, were followed by nearly
half a century of predominantly peaceful Portuguese ad-
ministration. But as African nationalism rose after World
War II, Guineans again began to challenge their colonial
rulers. Nationalist attacks on Portuguese administrative
and military posts were instigated in July 1961 by guerril-
las of the African Party for the Independence of Guinea
and Cape Verde (PAIGC), led by Amílcar Cabral. In Au-
gust, Cabral declared that political endeavours to obtain
the liberation of Portuguese Guinea and the Cape Verde is-
lands would be replaced by armed struggle.

Bitter guerrilla warfare ensued between the PAIGC Na-
tional Liberation Army (about 10,000 strong) and the Por-
tuguese armed forces (about 30,000 troops). The guerrillas
were unable to occupy the coastal towns and river ports,
but by 1971 they were firmly established in the interior. In
early 1973 Cabral was assassinated, and Aristides Pereira
assumed PAIGC leadership.

Independent Guinea-Bissau. By 1974 a military stale-
mate divided the African-ruled provinces of Guinea from
the European-ruled towns. However, the Portuguese army
overthrew the civilian dictatorship in Lisbon and negotiat-
ed independence for the African colonies, granting
Guinea-Bissau its independence on Sept. 10, 1974.
Cabral's Cape Verdean half-brother, Luís de Almeida
Cabral, became president of the country. Tension grew be-
tween the creolized middle class from Cape Verde and the
poorer, less educated indigenous population of the coast,
and in 1980 a coup d'état overthrew Cabral's government
and severed the PAIGC party links between the mainland
and the islands.   (D.Bi.)

Despite several coup attempts in the 1980s and early '90s
against the new head of state, João Bernardo Vieira, the
country's first free elections were held in 1994, and in 1997
Guinea-Bissau joined the Communauté Financière
Africaine (CFA). However, fiscal volatility caused in part
by CFA membership contributed to political unrest, lead-
ing to a brief civil war, followed by another coup in 1999
that unseated Vieira. Elections brought to power the na-
tion's first non-PAIGC government, under President
Kumba Ialá. When his rule turned repressive, he, too, was
removed in a bloodless coup in 2003. Interim president
Henrique Rosa oversaw elections in 2005 that returned
Vieira to power, but the country's political stability re-
mained uncertain.   (Ed.)

For later developments in the history of Guinea-Bissau,
see the BRITANNICA BOOK OF THE YEAR.

Liberia

Liberia is the only state in sub-Saharan Africa that was
never subject to colonial rule, and it is the oldest republic
on the continent. Located on the western African coast in
the tropical rain forest, and having an area of about 37,743
square miles (97,754 square kilometres), Liberia is bound-
ed by English-speaking Sierra Leone to the northwest;
French-speaking Guinea and Côte d'Ivoire to the north
and to the east, respectively; and the Atlantic Ocean to the
south and west. Monrovia, a port city, is the capital. In
1973 Liberia and Sierra Leone organized the Mano River
Union for economic cooperation; Guinea joined in 1980.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* The four physiographic regions of   Physical
Liberia parallel the coast. The coastal plains are about 350   regions
miles (560 kilometres) long and extend up to 25 miles
inland. They are low and sandy, with miles of beaches in-
terspersed with bar-enclosed lagoons, mangrove swamps,
and a few rocky promontories—the highest being Cape
Mount (about 1,000 feet [305 metres] in elevation) in the
northwest, Cape Mesurado in Monrovia, and Cape Palmas
in the southeast. Parallel to the coastal plains is a region
of rolling hills some 20 miles wide with an average maxi-
mum elevation of about 300 feet; a few hills rise as high as

Shostal Associates/Superstock

The Executive Mansion in Monrovia, Liberia.

500 feet. It is a region suitable for agriculture and forestry. Behind the rolling hills, most of the country's interior is a dissected plateau with scattered low mountains ranging from 600 to 1,000 feet in elevation; some mountains rise to 2,000 feet. A striking feature of the mountainous northern highlands along the Guinea frontier is Mount Nimba.

Drainage. The Mano and Morro rivers in the northwest and the Cavalla in the east and southeast are major rivers and form sections of Liberia's boundaries. Other major rivers are the Lofa in the north and, moving southward, the St. Paul, St. John, and Cestos, all of which parallel each other and flow perpendicular to the coast. The Farmington River is a source of hydroelectric power. Waterfalls, rapids, rocks, and sandbanks occur frequently in upstream sections of most rivers, inhibiting river traffic, and limiting navigation inland to short distances. During the rainy season there is often severe flooding in the coastal plains.

Liberia forms part of the West African Shield, a rock formation 2.7 to 3.4 billion years old, composed of granite, schist, and gneiss. In Liberia the shield has been intensely folded and faulted and is interspersed with iron-bearing formations known as itabirites. Along the coast lie beds of sandstone, with occasional crystalline-rock outcrops. Monrovia stands on such an outcropping, a ridge of diabase (a dark-coloured, fine-grained rock).

Soils. Four types of soil are found in Liberia. Latosols of low to medium fertility occur in rolling hill country and cover about 75 percent of the total land surface. Shallow, coarse lithosols, in the hilly and rugged terrain, cover about 16 percent of the land. Infertile regosols, or sandy soils, are found along the coastal plains. Highly fertile alluvial soils represent only about 3 percent of the land area and are utilized largely for agriculture.

Climate. The climate, especially on the coast, is warm and humid year-round, dominated by a dry season from November to April and by a rainy season from May to October. The dusty and dry harmattan (desert winds) blow from the Sahara to the coast in December, bringing relief from the high relative humidity. Deforestation and drought in the Sahel have affected the climate, lengthening the dry season by almost a month in some areas.

Tempera-
ture and
rainfall

Mean annual temperatures range between 65° F (18° C) in the northern highlands to 80° F (27° C) along the coast. Rainfall is irregular, and the rainy season varies in intensity and begins earlier at the coast than in the interior. The greatest amount of rainfall, 205 inches (5,200 millimetres), occurs at Cape Mount and diminishes inland to about 70 inches on the central plateau. The interior has hot but pleasant days and cool nights during the dry season.

Plant and animal life. Liberia has year-round evergreen vegetation. Many trees—such as red ironwood, camwood, whismore, teak, and mahogany—are valuable, but occur with other species, preventing easy harvest. Other trees of value are rubber, cocoa, coffee, and the raffia palm.

Liberia's rain forest abounds with animals such as the monkey, chimpanzee, small antelope, pygmy hippopotamus, and anteater. Elephants, bush cows (short-horned buffalo), and leopards are gradually disappearing. There are many reptiles, including three types of crocodiles and at least eight poisonous snakes. There are several unique species of bats and birds, and scorpions, lizards, and fish are numerous.

Settlement patterns. The present pattern of population distribution in Liberia is both a reflection of its migration history and a response to such social, economic, and cultural factors as war, employment, and superstition.

Migrants from north-central Africa, who began to arrive in the 13th century, originally settled in the hinterlands but were driven by overcrowding to the coast. Immigrants from the United States and the West Indies, and from neighbouring African countries, also settled on the coast. The former migrated mostly to selected areas such as Monrovia (the oldest immigrant settlement), Buchanan, Edina, Greenville, Harper, Robertsport, and Marshall. Scattered settlements were created along newly constructed or improved roads, while plantation and mining activities encouraged larger settlements in a few interior and coastal areas. There are more than 2,000 villages, the

majority of which are concentrated in central Liberia, in the northwest, and in the coastal region near Monrovia. The predominantly forested regions of south-central and northern Liberia have remained sparsely populated. The trend toward urbanization has had little impact on these villages. The result has been the segmentation of Liberian society into two coexisting subsystems—traditional-rural and modern-urban.

Monrovia, founded in 1822, is the focal point of political, economic, and cultural activities. Situated on the left bank of the St. Paul River on the ridge formed by Cape Mesurado, it commands an imposing view of the Atlantic Ocean and the coastal plains. The city and its outlying districts and suburbs occupy five square miles. The old style of architecture that once characterized it, reminiscent of that of the southern United States before 1860, is giving way to contemporary styles. All of the ethnic groups of Liberia are represented in its population, as are refugees, African nationals from other countries, and Europeans.

The people. *Ethnic and linguistic composition.* The people of Liberia are classified into three major groups: the indigenous people, who are in the majority and who migrated from the western Sudan in the late Middle Ages; black immigrants from the United States (known historically as Americo-Liberians) and the West Indies; and other black immigrants from neighbouring western African states who came during the anti-slave-trade campaign and European colonial rule. The Americo-Liberians are most closely associated with founding Liberia. Most of them migrated to Liberia between 1820 and 1865; continued migration has been intermittent. Americo-Liberians controlled the government until a military coup in 1980.

The 16 ethnic groups may be classified into three linguistic groups: the Mande, Kwa, and Mel (West Atlantic). The Mande are located in the northwest and central regions of Liberia and also in Senegal, Mali, Guinea, and Sierra Leone. Prominent among them are the Vai, who invented their own alphabet and who, in addition, use Arabic and English; the Kpelle, the largest Mande group, who are also found in Guinea; Loma (also found in Guinea); Gbandi; Gio (Dan); Mano; Mende; and Malinke. The Kwa include the Bassa, the largest group in this category and the largest ethnic group in Monrovia; the Kru and Grebo, who were among the earliest converts to Christianity; the De; Belle (Belleh); and Krahn. The Kwa-speaking group occupies the southern half of the country. The Mel group includes the Gola and Kissi, who are also found in Sierra Leone and are known to be the oldest inhabitants of Liberia. These people live in the north and in the coastal region of the northwest.

Religion. Liberians are a religious people. About two-thirds of the people are Christian, about 15 percent are Muslim, and almost one-fifth profess other religions, primarily traditional beliefs. The largest number of Christians are the Kpelle, followed by the Bassa. The Muslims are found predominantly among the Mande peoples in the northwest region of the country.

Demographic trends. More than two-fifths of the population of Liberia is under 15 years of age; only about 5 percent is older than 65. The annual rate of natural increase is one of the highest in sub-Saharan Africa, and, because emigration is negligible, the country's annual rate of population growth is one of the highest in the world. Life expectancy, about 54 years for males and 56 years for females, is high by African standards. About 40 percent of the population lives in urban communities, and there is a high rural-to-urban movement, especially to Monrovia. Other destinations include enclaves around rubber plantations and mines.

The economy. The Liberian economy is predominantly agrarian, and raw materials, equipment, and consumer goods are imported. Production for export is carried out on a large scale through foreign investment in rubber, forestry, and mining. Foreign ships registering under a Liberian "flag of convenience" have made Liberia the world's foremost nation in registered shipping tonnage. Liberia nevertheless remains a primarily agricultural and underdeveloped country. The distribution of wealth is uneven, the coastal districts receiving a greater share of

Monrovia

economic benefits than the hinterland, after which the administrative centres are the next beneficiaries.

After the mid-1970s the once-vibrant economy took a sharp downturn. Between 1976 and 1980 sluggish demand and low prices stagnated the economy and the annual growth rate plunged. But gradual signs of recovery appeared, especially in agriculture and forestry. In the early 1990s, however, civil war disrupted Liberia's economy.

Liberia's economy is mixed and there is no nationalization of industry. The government, which is the largest single employer, operates several public corporations. There is a national Federation of Labour Unions, a federation of trade unions, and several other employees' unions, but no employers' association.

About 70 percent of the work force is employed in agriculture; the rest work in manufacturing, sales, services, and administration and management. About 40 percent of the total labour force is made up of women. More women than men are employed in agriculture.

The U.S. dollar, previously legal tender in Liberia, is no longer in circulation. The value of the local Liberian dollar retains parity with the U.S. dollar, however. Government revenues are derived from income, profits, property, domestic transaction, foreign trade, and maritime taxes. About one-third of economic development funding has generally been derived from foreign sources, both bilateral and multilateral.

Liberia is a member of two regional economic unions—the Mano River Union, a free trade group to which Sierra Leone and Guinea also belong, and the Economic Community of West African States (ECOWAS).

Resources. Liberia is rich in natural resources. It is among the leading producers of iron ore—which it has produced since 1951—in Africa, and it is one of the principal exporters of iron ore in the world. Its sizable reserves are found primarily in four areas: the Bomi Hills, the Bong Range, the Mano Hills, and Mount Nimba, where the largest deposits occur. Other minerals include diamonds, gold, lead, manganese, graphite, cyanite (a silicate of aluminum, with thin bladelike crystals), and barite. There are possible oil reserves off the coast.

There is vast potential for the development of hydroelectric power. About half of Liberia's electricity is from hydroelectric sources. The Mount Coffee hydroelectric station outside Monrovia on the St. Paul River is the country's largest hydroelectric installation.

Water supplies have been improved in both rural and urban areas so that some 40 percent of the population has access to potable water. Surface water is abundant, and groundwater reserves are ample and regularly replenished by the country's heavy rainfall.

Agriculture, forestry, and fishing. Agriculture is the fastest-growing sector of the economy. About half the land area is suitable for cultivation, though less than 5 percent is actually cultivated. Commercial farms are often operated by foreigners. Traditional farms, which comprise the largest number, are usually cultivated by slash-and-burn methods. Traditional farming, though less capital-intensive, contributes nearly twice as much to Liberia's gross domestic product as commercial farming.

Traditional farmers practice mixed cultivation of rice, cassava, and vegetables. They also raise goats, sheep, chickens, and ducks. Cultivation of cash crops such as coffee, cocoa, oil palm, sugarcane, and swamp rice is increasing. Domestic rice production meets about 75 percent of the country's needs. The rest is imported, principally from the United States.

Liberia's climate is suitable for rubber production; the necessary plants thrive on the country's poor soils. In 1926, the Firestone Tire and Rubber Company of the United States obtained a concession for rubber cultivation. Rubber has become by far the country's most valuable commercial crop, with coffee and cocoa increasing in importance. Kola nuts, peanuts, and cotton are also produced, and cattle and pigs are raised.

Rain forests produce fine hardwood timber, especially in the east of the country, but also in the centre and in the west. Timber concessions operate in the southeast and northwest. Substantial amounts of timber are produced,

but exploitation of the forest resources is difficult because of poor roads and shortage of labour. Of the approximately 250 species of forest trees about 90 are marketable. Forest depletion continues despite government reforestation regulations.

Deep-sea fishing is important, and the catch is largely mackerel, barracuda, and red snapper. Kru and Fanti fishermen, the latter from Ghana, have traditionally been the suppliers of fish to coastal areas but are supplemented by Liberian fishing companies. Inland fish-breeding ponds provide a source of protein.

Industry. To export the ores, iron interests have built railroads connecting the mines with Monrovia and Buchanan. Iron ore is extracted by open-pit mining, while gold and diamonds are extracted by placer mining. Traditional, small-scale mining for gold and diamonds continues.

Manufacturing enterprises have increased greatly since 1960. Predominantly private and foreign-owned, most serve the local market. Near Monrovia there is a petroleum refinery as well as a cement plant. There are also explosives, paint, pharmaceutical, and cosmetics plants. Bricks, tiles, cement blocks, lumber and furniture, soap, and footwear are also manufactured, and there are several distilleries. The problem of foreign exchange and the high cost of raw materials for these industries cause frequent market shortages, and the failure rate among manufacturing businesses is high.

Instability and civil war have held Liberia's potentially lucrative tourist industry in check. Tourist facilities are concentrated near beaches in Monrovia and Robertsport and near Lake Piso. The Lakpazee Zoo and the National Cultural Center at Kendeja, Providence Island near Monrovia, and the Kpatawee Waterfalls on the Zor River near Suakoko are the principal tourist attractions.

Finance and trade. Among the several government-sponsored banks are the National Bank of Liberia, the National Housing and Savings Bank, the Agricultural and Cooperative Development Bank, and the Liberia Bank for Development and Investment. In addition there are private banks, insurance companies, and credit unions.

Countries of the European Union, especially Germany, and the United States are the principal markets for Liberian exports. Iron ore and rubber account for almost 75 percent of Liberian export earnings, followed by logs and timber, diamonds, coffee, and cocoa. Food is the primary import; others include machinery and transport equipment, beverages, tobacco, manufactured goods, fuels, lubricants, and chemicals. The United States and Germany are the largest suppliers of imports.

Transportation. Only a small percentage of Liberian roads are paved. Primary roads connect administrative and economic centres and provide access to the road systems of neighbouring countries.

Monrovia is the principal commercial port, and it also has facilities for transshipping iron ore and liquid latex. Nimba Range iron ore is shipped from Buchanan, while the ports at Greenville and Harper are used primarily for the shipment of rubber and forest products. All ports are administered by the National Port Authority.

Liberia has two major airports, Robertsfield International, and James Spriggs Payne Airport, both near Monrovia. More than 100 airfields and airstrips dot the country's interior.

Administration and social conditions. *Government.* Liberia's government is patterned after that of the United States with the executive, legislative, and judicial branches. Political parties were legalized in 1984 and civilian rule was established in 1986. However, considerable political unrest and violence precluded any stable leadership from power through the mid-1990s. The 1986 constitution provides for direct election by popular vote of the president for a six-year term.

Members of the bicameral National Assembly, who serve six-year terms in the House of Representatives and nine-year terms in the Senate, are also elected directly. The constitution calls for a multiparty system. Major political parties include the National Democratic Party, the Unity Party, the Liberian Action Party, the Liberia Unification

(marginal note, left column) Minerals

(marginal note, right column) Manufacturing

Party, and the United People's Party. The main opposition parties are the National Patriotic Front of Liberia and the United Liberation Movement of Liberia for Democracy. The Supreme Court is headed by a chief justice assisted by five associate justices, all of whom are appointed by the president.

Each of the country's 11 counties and two territories is headed by a superintendent, who is the direct representative of the president and has a council. The mayor of the capital city of the county also has a council. The counties are divided into districts, chiefdoms, and clans administered by county commissioners and paramount and clan chiefs. The ethnic peoples are allowed, as far as possible, to govern themselves according to customary law. County Development Associations assist in the delivery and improvement of government services.

Education. Since 1939 education has been compulsory for children between the ages of six and 16 and is free at the primary and secondary levels. In 1974 Liberia became a full member of the West African Council in order to provide an international yardstick for measuring the quality of its education.

The government provides for the education of teachers and sponsors the employment of foreign teachers. International aid has also enabled the government to expand the quality and availability of education. There are several vocational schools, including the Booker Washington Agricultural and Industrial Institute at Kakata, a government school. Advanced training is provided at the University of Liberia (1951) in Monrovia, at Cuttington University College (1889) in Suakoko (Episcopalian), and at the William V.S. Tubman College of Science and Technology (1978) in Harper. Several community colleges have also been established in the Monrovia area. The Monrovia Torrino Medical College trains paramedical students. Liberians who study abroad receive advanced training under a government foreign scholarship program and from donor agencies.

Health and welfare. Conditions remain poor, although much progress has been made in providing better health facilities. Malaria and leprosy are major health problems, and influenza, hernias, intestinal worms, trypanosomiasis (sleeping sickness), schistosomiasis, and elephantiasis are also prevalent. The government conducts inoculation campaigns to combat smallpox and yellow fever. Yaws is no longer a serious problem, following a World Health Organization control program, but tuberculosis has been difficult to eradicate. Dysentery, malaria, and diarrhea are the most important causes of infant mortality, which, at about 120 per 1,000 births, is high by world standards but about average for western Africa.

Modern hospitals include the John F. Kennedy Memorial Hospital in Monrovia, sponsored by the U.S. Agency for International Development, the Roman Catholic Hospital at Monrovia, and Phebe Hospital in Bong county, all of which have nursing schools and medical teaching units attached to them.

The Ministry of Public Works supervises low-cost housing projects. Housing is expensive, and most building equipment is imported.

Intermarriage and economic progress have been important in breaking down social divisions. Mines and plantations located throughout the country have helped the slow trend toward a more equitable distribution of income. In the coastal districts, government jobs, foreign businesses, and local markets provide greater opportunities for economic and social advancement.

Cultural life. Traditional and Western life-styles co-exist; however, traditional values, customs, and norms influence the Western type considerably. In cities both Western and African music and dancing styles are in vogue, but in rural areas traditional rhythms are favoured. Schools instruct students in the legends, traditions, songs, arts, and crafts of African culture, and the government promotes African culture through such agencies as the National Museum in Monrovia, the Tubman Center for African Culture in Robertsport, and the National Cultural Center in Kendeja, which exhibits architecture of the 16 ethnic groups of Liberia. Mask making is an artistic pur-

suit that is also related to the social structure of some ethnic groups. Musical festivals, predominantly religious, are held in most communities. The University of Liberia has an arts and crafts centre. There are several libraries, including a children's library in Monrovia and a National Public Library.

Association football (soccer) is the most popular sport. An intercounty football competition is held for the annual championship. The University of Liberia and Cuttington University College hold annual sports competitions.

Monrovia has five daily newspapers including the *Daily Observer,* the largest and most prestigious. A few magazines are published annually. Officially, there is press freedom, but newspapers are banned occasionally for violating government policies on information.

There are four radio stations and one television station. International telecommunication services are available through direct satellite links between Liberia, the United States, Italy, and France.

For statistical data on the land and people of Liberia, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.   (A.B.J.)

HISTORY

Outsiders' knowledge of the west of Africa began with a Portuguese sailor, Pedro de Sintra, who reached the Liberian coast in 1461. Subsequent Portuguese explorers named Grand Cape Mount, Cape Mesurado (Montserrado), and Cape Palmas, all prominent coastal features. The area became known as the Grain Coast because grains of Melegueta pepper, then as valuable as gold, were the principal item of trade.

In the beginning of the 19th century the tide started to rise in favour of the abolition of slavery, and the Grain Coast was suggested as a suitable home for freed American slaves. In 1818 two U.S. government agents and two officers of the American Colonization Society (founded 1816) visited the Grain Coast. After abortive attempts to establish settlements there, an agreement was signed in 1821 between the officers of the society and local African chiefs granting the society possession of Cape Mesurado. The first American freed slaves landed in 1822 on Providence Island at the mouth of the Mesurado River. They were followed shortly by Jehudi Ashmun, a white American, who became the real founder of Liberia. By the time Ashmun left in 1828 the territory had a government, a digest of laws for the settlers, and the beginnings of profitable foreign commerce. Other settlements were started along the St. John River, at Greenville, and at Harper. In 1839 Thomas Buchanan was appointed the first governor. On his death in 1841 he was succeeded by Joseph Jenkins Roberts, a black man born free in Virginia in 1809; Roberts enlarged the boundaries of the territory and improved economic conditions.

The early republic. When the American Colonization Society intimated that Liberia should cease to be dependent upon it, Roberts proclaimed it an independent republic in 1847. Independence was recognized in 1848–56 by most of the great powers, though formal recognition by the United States did not come until 1862.

At the time independence was declared, a constitution based on that of the United States was drawn up. Roberts, who had been elected the first president of the republic, retained that office until 1856. During this period the slave trade, theretofore illicitly carried on from various nominally Liberian ports, was ended by the activity of the British and U.S. navies.

In 1871 the first foreign loan was raised, being negotiated in London nominally for £100,000. The loan was unpopular, and still more unpopular was the new president, Edward J. Roye, who was deposed and imprisoned at Monrovia. Roberts was called back to office. He served until 1876.

During the early days of Liberia there were constant frontier troubles with the French on the Ivory Coast and the British at Sierra Leone. The Liberians tried to extend their authority inland, although they were still unable to control all the coastal area they claimed. Efforts to end the frontier disputes resulted in treaties with Great Britain in

The Grain Coast

Joseph Jenkins Roberts

1885 and with France in 1892. In 1904 President Arthur Barclay, who was born in Barbados, initiated a policy of direct cooperation with the peoples of the region and, with another loan from London, made real efforts at reform. The foreign debt, however, was a burden, and the government was unable to exert effective authority over the interior for more than 20 miles inland. In 1919 an agreement was signed transferring to France 2,000 square miles of hinterland that Liberia had claimed but could not control.

Outside intervention. In 1909 a commission appointed by President Theodore Roosevelt of the United States investigated political and economic conditions in Liberia and recommended financial reorganization. A loan of $1.7 million, secured by customs revenue, was raised by an international consortium of bankers in 1912, and a receivership of customs was set up, administered by appointees of the British, French, and German governments and a U.S. receiver-general. A frontier police force was organized by officers of the U.S. Army, with the result that Liberian authority was better maintained. However, this promising new regime was upset by World War I. Revenues dropped to one-fourth of normal, and the financial situation steadily deteriorated.

Firestone rubber concession

The Firestone Tire and Rubber Company obtained a concession of 1,000,000 acres (400,000 hectares) in 1926 for a rubber plantation. At the same time, a loan was arranged through the Finance Corporation of America, a Firestone subsidiary. The Liberian government thereby consolidated and bonded all its external and internal debts and placed the country's finances on a relatively stable basis. Administration of the customs and internal revenue was placed in the hands of a U.S. financial adviser. In 1952 the government was able to liquidate its foreign debt for the first time since accepting the English loan of 1871.

An investigation by the League of Nations of forced labour and slavery in Liberia brought about the resignation of President Charles King and the election of Edwin Barclay to the presidency in 1931. There followed a long and unsuccessful struggle to work out a plan of financial assistance with the Council of the League of Nations; ultimately the League Council withdrew its plan.

World War II and after. The new significance of Liberia became apparent after the outbreak of World War II. During the war, Liberia's rubber plantation was the only source of natural latex rubber available to the Allies, apart from plantations in Ceylon (now Sri Lanka). In 1942 Liberia signed a defense agreement with the United States. This resulted in the undertaking of a program of strategic road building and the construction of an international airport and a deepwater harbour at Monrovia. U.S. money was declared legal tender in Liberia in 1943, replacing British West African currency. In 1943 William V.S. Tubman was elected to his first term as president. Liberia declared war against Germany and Japan in January 1944 and in April signed the declaration of the United Nations. In December 1960 Liberia became a member of the UN Security Council and from that time took an active part in African and international affairs. In 1963 Liberia became a member of the Organization of African Unity (now the African Union) at its inception. In May 1964 the United States and Liberia signed an agreement to transfer the free port of Monrovia to the government of Liberia. Tubman died in 1971, shortly after his election to a seventh term as president, and was succeeded by Vice President William R. Tolbert.

A decline in world prices for Liberia's chief exports, iron ore and natural rubber, brought financial hardship to the country during the 1960s and early 1970s. Foreign loans helped sustain the economy during that period.

In April 1980 Tolbert was killed in a coup led by Master Sergeant (later General) Samuel K. Doe, who became head of state and chairman of the People's Redemption Council (PRC). The PRC promised a new constitution—which became effective in 1986—and a return to civilian rule. Elections were held in 1985 with several parties participating but were widely criticized as fraudulent. Doe was inaugurated as the first president of the Second Republic in January 1986. His rule ended in 1990 after civil war—pri-

marily between the Krahn and the Gio and Mano peoples—erupted. A multinational West African force, the Economic Community of West African States (ECOWAS) Monitoring Group, attempted to restore order, but the leaders of two rebel groups, Charles Taylor and Prince Johnson, contended for power after Doe's downfall and execution. The war dragged on for seven years, as new factions arose and neighbouring countries became enmeshed in the strife. The toll on the civilian population and the economy was devastating. A truce was finally achieved in 1996. In elections held in 1997, Taylor's National Patriotic Front of Liberia Party achieved a clear majority.

ECOWAS peacekeeping forces helped maintain a shaky peace until their withdrawal in early 1999. By the end of the year, rebels were on the attack in northern Liberia. The insurgency slowly spread southward, killing thousands and displacing tens of thousands in the fighting. Government troops could not stop the rebel advance, and in August 2003 Taylor fled the country; the UN was in charge of peacekeeping operations by the end of the year.

(D.R.P./S.E.H./Ed.)

For later developments in the history of Liberia, see the BRITANNICA BOOK OF THE YEAR.

Nigeria

Nigeria—in full, the Federal Republic of Nigeria—is the largest of the western African coastal states. Its population is the largest of any country in Africa and one of the largest in the world. With an area of 356,669 square miles (923,768 square kilometres), it is the 14th largest state on the continent. It is bordered to the north by Niger, to the east by Chad and Cameroon, to the south by the Gulf of Guinea, and to the west by Benin. The former national capital of Lagos, on the southwest coast, was replaced in 1991 by the centrally located town of Abuja, in the Federal Capital Territory, although the judiciary and some ministries have remained in Lagos.

Modern Nigeria dates from 1914, when the British protectorates of Northern and Southern Nigeria were joined. The country became independent on Oct. 1, 1960, and in 1963 adopted a republican constitution but elected to stay a member of the Commonwealth. English remains the official language, since more than 200 different languages are spoken by the many groups living in the country. From 1980, however, Yoruba, Hausa, and Igbo (Ibo), the languages spoken by the three largest ethnic groups, could also be used for official transactions at the federal level. Cultural contacts with the more distant English-speaking countries of Ghana and Sierra Leone, and more recently with Liberia, remain stronger than those with the adjacent French-speaking Benin, Niger, and Cameroon.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Nigeria consists of several eroded surfaces, occurring as plateaus, at elevations of 2,000 feet (610 metres), 3,000 feet, and 4,000 feet above sea level. The coastal areas, including the Niger Delta, as well as the Lake Chad Basin and the western parts of the Sokoto region in the far northwest, are underlain by young, soft sedimentary rocks. Gently undulating plains, which become waterlogged during the rainy season, are found in these areas. In much of the southwest and in most of the north-central part of the country, the underlying rocks are crystalline, and the characteristic landforms are high plains with broad, shallow valleys dotted with numerous hills or inselbergs (steep-sided masses of rock left after erosion). Dome-shaped isolated hills and elongated ridges occur in the sandstone plateau region near the confluence of the Niger and Benue rivers.

Plateaus and undulating plains

The Nsukka–Okigwe cuesta, northeast of the Niger Delta, contains the Enugu (Enugu-Okigwe) escarpment, which rises abruptly for approximately 600 feet above the Cross River plains. Other prominent relief features include the Jos Plateau and the Biu Plateau, both extensive lava surfaces dotted with numerous extinct volcanoes.

Drainage. There are three major drainage areas in Nigeria—the Niger–Benue Basin; the Lake Chad Basin; and the coastal, or Gulf of Guinea, basin. The Niger River,

for which the country is named, and the Benue, its largest tributary, are the principal rivers. The Niger has many rapids and waterfalls, but the Benue is not interrupted by either and is navigable throughout its length except during the dry season. Rivers draining the area north of the Niger–Benue trough include the Sokoto, the Kaduna, the Gongola, and the rivers draining into Lake Chad. The coastal areas are drained by short rivers that flow into the Gulf of Guinea. River basin development projects have resulted in the creation of many large man-made lakes, including Lake Kainji on the Niger and Lake Bakolori on the Rima.

The Niger Delta is a vast low-lying region through which the waters of the Niger River drain into the Gulf of Guinea. Oxbow lakes, river meander belts, and prominent levees are characteristic landforms in this region. Large freshwater swamps give way to brackish mangrove formations near the seacoast.

Soils. There are four major soil groups: (1) the ferruginous tropical soils (red and brown), which cover the largest area and are found primarily in the regions underlain by crystalline rocks, (2) the ferralsols, which are localized in areas of older sedimentary rocks, (3) the regosols and brown soils, developed on loose sandy materials consisting of wind-borne deposits and riverine sands and found primarily in the dry north, and (4) the hydromorphic and organic soils, confined largely to areas of young sedimentary rocks along the coast and river floodplains. The most productive soils agriculturally belong to the first group. Along the coast and in the forest belt, where the rainfall is greatest and the soils are heavily leached, the soils readily lose their fertility. In parts of the north, where there is a marked dry season, a dense surface layer of laterite develops, making these soils difficult to cultivate.

Climate. Nigeria has a tropical climate with rainy and dry seasons. It is hot and wet throughout the year in the southeast but dry in the southwest and farther inland. Three climatic patterns are distinguished: (1) a tropical wet climate in the southeast, with high temperatures and heavy rainfall throughout the year; (2) a tropical wet and dry, or savanna, climate in the north and west; and (3) a dry, or steppe, climate in the far north.

In general, the length of the rainy season decreases from south to north. In the south the rainy season lasts from March to November; in the far north it lasts only from mid-May to September. In August there is a marked interruption in the rains in the south, resulting in a short dry season often referred to as the "August break."

Rainfall is heavier in the south, especially in the southeast, which receives more than 120 inches (3,050 millimetres) of rain a year, as compared with 70 inches in the southwest. Rainfall decreases progressively away from the coast; the far north receives no more than 20 inches a year.

Temperature and humidity remain relatively constant throughout the year in the south. In the north considerable seasonal variation occurs, and, during the dry season, the daily temperature range becomes great as well. On the coast the mean monthly maximum temperatures are steady throughout the year, remaining at a nearly constant 90° F (32° C) at Lagos and at about 91° F (33° C) at Port Harcourt; the mean monthly minimum temperatures remain approximately at 72° F (22° C) for Lagos and at 68° F (20° C) for Port Harcourt. In the northeastern city of Maiduguri, on the other hand, the mean monthly maximum temperature may exceed 100° F (38° C) during the hot months of April and May, while in the same season frosts may also occur at night. In general, mean maximum temperatures are higher in the north, while mean minimum temperatures are lower. The humidity is high, but it falls during the harmattan (the hot, dry, northeast trade wind), which blows for more than three months in the north but rarely for more than two weeks along the coast.

Plant and animal life. Like rainfall patterns, the main vegetation patterns run in broad east–west belts, parallel to the equator. Mangrove and freshwater swamps occur along the coast and in the Niger Delta. A few miles inland, swamps give way to dense tropical rain forests. The oil palm, which is economically valuable, grows wild and is usually preserved when the forest is cleared for cultivation.

In the more densely populated parts of the southeast, the original forest vegetation has been replaced by open palm bush. In the southwest large areas of forest have been replaced by cacao and rubber farms.

The savanna (tropical grassland) occupies the area north of the forest belt and is studded with baobab, tamarind, and locust bean trees. The savanna becomes more open in the far north and is characterized by scattered, stunted trees and short grass. Semidesert conditions appear in the Lake Chad region, where various species of acacia and the doum species of palm are common. Gallery forests (narrow forest zones along rivers) are also characteristic of the open savanna in the north.

In densely populated areas of the savanna, such as around Sokoto, Kano, and Katsina, the vegetation has been depleted as a result of continuous cropping, overgrazing, and bush burning. The near-total decimation of plant life has resulted in the gradual southward advance of the Sahara in the far northern districts.

Camels, antelope, hyenas, lions, and giraffes inhabit the savanna region, and the red river hog, the forest elephant, and the chimpanzee live in the rain forest belt. Animals found in both forest and savanna include leopards, golden cats, monkeys, gorillas, and wild pigs. Rodents such as the squirrel, porcupine, and cane rat constitute the largest family of mammals. The northern savanna abounds in Guinea fowl. Other common birds include quail, vultures, kites, bustards, and gray parrots. The rivers contain crocodiles, hippopotamuses, and a great variety of fish.

Settlement patterns. Marked differences exist between north and south not only in physical landscape, climate, and vegetation but also in the social organization, religion, literacy, and agricultural practices of the people. These differences form the basis of the division of Nigeria into three main regions—the south, or Guinea coastlands; the middle belt; and the north, or Nigerian Sudan.

The south is the most economically developed part of Nigeria. Its forest resources are intensively exploited, and its tree crops are harvested on peasant farms and commercial plantations. All of the major industrial centres and oil fields, as well as the seaports, are concentrated in the region. The south has several cultural regions, the most important of which are the Yoruba in the west, the Benin in the central west, and the Igbo–Ibibio in the east.

The middle belt is the most sparsely settled and least developed part of Nigeria. It covers about two-fifths of the land area of the country but supports less than one-fifth of the total population. The inhabitants of the middle belt belong to more than 180 linguistic groups. Before 1970 large-scale development was restricted to a few government-supported projects, such as the Kainji Dam and the Bacita sugar project, and a few industries in the new towns of Jos and Kaduna. After the national administrative reorganization of 1975, the region gained importance because seven of the 19 state capitals as well as the 2,800-square-mile Federal Capital Territory are located there. In addition, during the early 1980s a giant iron and steel complex was built at Ajaokuta, near Lokoja.

Until the beginning of the 20th century, when a new economic pattern was created by the construction of a railroad to the coastal ports, the Nigerian Sudan maintained regular trans-Saharan contacts with the Mediterranean and the Middle East. Except in the Lake Chad Basin, where the Kanuri people established the state of Bornu, the Nigerian Sudan is dominated by a blend of Hausa–Fulani culture. It is a cattle zone inhabited by the nomadic cattle-owning Fulani and by the Hausa, who are settled cultivators. Islām is the predominant religion.

The main concentrations of people are in the forest belt west of the Cross River and in the western half of the extreme north. Parts of the Igbo and Ibibio areas in Nigeria are the most densely settled areas in Africa south of the Sahara. This concentration of agricultural people occurs in a region that has heavily leached and impoverished soils, and there is a food deficit. Many people leave the region to seek employment in other parts of the country. The second region of dense population in the forest belt occurs in the cacao-growing Yoruba areas, which attract many migrants from the congested Igbo and Ibibio areas.

Marginal notes:

The harmattan season

Regional differences

Population distribution

States of Nigeria, 1996.

In the extreme north there are two regions of dense population—the Sokoto area and the Kano–Katsina area. The Kano concentration is based on intensive agriculture in an area of relatively fertile soils, but the densely settled areas around Sokoto and Katsina have impoverished soils and do not produce enough food for the local population.

Smaller pockets of dense population occur in the tin fields of the Jos Plateau, in the southern Tiv region, and in the Okene area. The remaining, and by far the greater, part of the country is sparsely settled; vast areas of the middle belt, the Lake Chad Basin, and the eastern Cross River area are virtually uninhabited.

Rural settlement   About four-fifths of the people live in villages. Closely nucleated settlements occur along the coast, in the Yoruba area in the southwest, and in the Hausa and Kanuri areas of the far north. In parts of the Igbo and the Anang–Ibibio regions in the southeast and of the Tiv area in the middle belt, settlements consist of dispersed homesteads called compounds. Each compound houses a man, his immediate family, and some relations. A number of compounds make up the village, usually inhabited by people claiming a common ancestor—often the founder of the village.

House types change as one moves inland. In the coastlands the walls consist of bamboos tied together with ropes, and roofs are made of bamboo leaf mats. Bamboos, ropes, and mats are made from the raffia palm, which abounds in the region. Rectangular mud houses with mat roofs are found in the forest belt; the houses of the more prosperous have corrugated iron roofs. In the savanna areas of the middle belt and in parts of the north, houses are round mud buildings roofed with sloping grass thatch; flat mud roofs are used in the drier areas of the extreme north.

Each village has a chief, or headman, who usually is one of the oldest men in the community and rules by consent of the people. This is particularly true in the eastern states. In Yoruba areas, and in most parts of the northern states, the chief is chosen by, or with the consent of, the region's traditional ruler. The chiefs are usually powerful and highly respected. A characteristic feature of village life is the age-grade system of social organization, which groups together people of the same age group.

Urban settlement   Only the Yoruba, Hausa, Bini, Kanuri, and coastal peoples were town dwellers before the 20th century. The Yoruba, of whom about half live in towns of more than 5,000, are the most urbanized people in tropical Africa. Their towns, most of which are several hundred years old, were originally administrative and trading centres; most have retained these functions. The principal Yoruba towns are Ibadan, Ogbomosho, Abeokuta, Ife, and Oyo.

The northern towns of the Nigerian Sudan, including Kano, Zaria, Sokoto, and Katsina, are much older than the Yoruba towns. Owing their growth to the trans-Saharan trade, as well as to the agricultural wealth of the Sudan, these ancient towns were unplanned, and they consist of an amorphous assemblage of mud buildings.

Coastal fishing and salt-trading villages grew into towns in response to the slave trade and the later trade in palm oil between the coastal peoples and Europeans. These towns include Bonny, Opobo Town, Okrika, Buguma, Brass, Forcados, Creek Town, and Calabar (Duke Town). At the beginning of colonial rule, these port towns had a more cosmopolitan population than the towns of the Yoruba area and the far north, but they were much smaller.

During the period of British rule, new towns grew up and the older ones grew larger, except along the coast, where all the older towns, excluding Lagos, declined in size or even ceased to exist. Many towns originally were primarily administrative centres, but—like Port Harcourt, Lagos, and Ibadan, as well as the Sudanese towns of Kano and Kaduna—they have become industrialized.

Ancient and modern towns

Lagos is the largest conurbation in Nigeria. Primarily a Yoruba town, it was founded in the late 17th century as a small fishing and trading settlement. Lagos retains the characteristics of a preindustrial city, even though it is by far the most industrialized city in the country. The creation of several states since 1967 diverted some of the industries and job-seeking migrants from Lagos to the new state capitals, especially the older and larger ones such as Ibadan, Kaduna, Kano, and Enugu. Some small towns, notably Minna, Uyo, Makurdi, Maiduguri, and Bauchi, experienced remarkable population and economic growth after becoming state capitals.

The people.   Over the centuries Nigeria has evolved a great diversity of peoples and cultures. It was in Nigeria that the Bantu and Semi-Bantu, migrating from southern and central Africa, intermingled with the Sudanese Negro. Later smaller groups such as the Shuwa Arabs, the Tuareg, and the Fulani, who are concentrated in the far north, entered northern Nigeria in waves of migration across the Sahara.

The earliest occupants of Nigeria settled in the forest belt and in the Niger Delta, into which they retreated from the invaders of the northern savanna zone. During the period of the slave trade the social organization of coastal peoples, including those of the Niger Delta, was altered radically, in part because of the forced migrations of people from the interior into the area and in part because of contact with European traders. The early colonial period witnessed more cultural intermingling in the coastal towns, notably Calabar, Warri, and Abonnema, where Syrian, Lebanese, and European traders settled.

Ethnic composition.   There are estimated to be more than 250 ethnic groups. Each group occupies a territory that it considers to be its own by right of first occupancy and inheritance. Nonmembers of a given group who have lived and worked for several decades in the territory of

Robert Frerck—Odyssey Productions

Court musicians at the Emir's Palace, Kano, Nigeria.

The Hausa

the group are still considered to be aliens. In most rural areas, such aliens may not acquire outright title to land; yet there has been considerable migration of people from one ethnic territory to another in search of farmland.

There are three major ethnic groups in the country, of which the Hausa are the most numerous. The Hausa who live in the far north have become integrated with the minority Fulani who conquered Hausaland in the early 19th century, and the great majority of both groups are Muslims. Although the town Fulani intermarry freely with the Hausa and other groups, they continue to control the administration of the Hausa towns. The cattle Fulani generally do not intermarry. They speak the Fulani language—Fulfulde—rather than Hausa.

Another large and politically dominant group consists of the Yoruba-speaking peoples of southwestern Nigeria, who, like the Hausa and the Fulani, have ancient connections with the Middle East. The Yoruba, although they are farmers, often live in large preindustrial cities. Each Yoruba subgroup is ruled by a paramount chief, or oba, who is usually supported by a council of chiefs. The *oni* of Ife, who is the spiritual leader of the Yoruba, and the *alafin* of Oyo, who is their traditional political leader, are the most powerful rulers; their influence is acknowledged throughout the Yoruba areas.

The Igbo-speaking peoples are one of the largest ethnic groups in Nigeria. In the southeastern region, where the core area of Igbo territory is located, the great majority of people live in small dispersed settlements. A much smaller proportion (about 10 percent) of the Igbo live in large preindustrial towns and are culturally much closer to the Edo of neighbouring Benin City than to the Igbo east of the lower Niger valley. Traditional Igbo society has been democratic; and, outside the western Igbo districts of Bendel state, the largest political unit has been the village group, ruled by a council of elders (chosen by merit, not heredity) rather than by a chief.

Less numerous groups include the Ibibio, who live near the Igbo, with whom they share many traits, and the Edo people of Benin City, whose culture has been influenced by their Yoruba neighbours. In the middle belt, where the greatest concentration of ethnic groups (more than 180) occurs, the Tiv and the Nupe are the largest groups. Both are settled cultivators, but while Nupe society is hierarchical, that of the Tiv tends to be decentralized.

Linguistic composition. Each ethnic group has its own language, of which there may be several dialects. The major languages of Nigeria are Hausa, Yoruba, Igbo, Ibibio, Kanuri, Tiv, and Ijo, in that order. Hausa is by far the most widely spoken language, partly because between 1951 and 1967 Hausa was an official language of the northern states. The continued political domination of the country by the Hausa/Fulani has also contributed to the spread of the Hausa language. The creation of more states has resulted in the proliferation of written languages, since radio stations relay news in all the major languages of each state, some of which are also used in local newspapers and magazines. Since about 1950 the translation of the Bible into a number of Nigerian languages has also led to an increase in the number of written languages.

Traditional religion

Religions. The three main religions are traditional beliefs, Islām, and Christianity. Adherents of traditional religion worship the supreme God (Olorun Olodumare in Yoruba, Chukwu in Igbo, Allah in Hausa, and Abasì Ibom in Ibibio) through a number of intermediaries or lesser gods. At the beginning of the 20th century, most Nigerians were followers of traditional religion, but during the 1963 census, 47 percent of the people were recorded as Muslims and 35 percent as Christians. However, many professing Muslims and Christians now openly perform certain rites or rituals of traditional religion that are no longer condemned as they were during the early colonial period.

Religious freedom is guaranteed by the constitution, and Muslims and Christians live and work together. However, the country has since the early 1970s witnessed a number of religious riots sparked by Muslim fundamentalists. The greatest concentration of Muslims is in the northern states, where three-quarters of the people profess the religion. Islām has also gained strength in the southern states of

Lagos, Ogun, and Oyo, where Muslims outnumbered Christians by the early 1980s. Christians make up more than three-quarters of the population in the eastern states, and Christianity has made great inroads since 1960 in the middle belt, which is now the main area of religious conflict.

The main established Christian groups are Roman Catholic, Methodist, Anglican, and Baptist. There is an increasing number of separatist Christian groups, of which the largest are the Cherubim and Seraphim, the Celestial Church of Christ, and the Brotherhood of the Cross and Star. The popularity of these spiritualist sects established by indigenous peoples is a threat to the older established churches, which have introduced drumming and dancing—formerly the distinguishing features of the separatist churches—into their services to avoid losing more members. The rapid growth in the membership of these sects, which, like Islām, allow a member to marry more than one wife, has also posed a threat to Islām and is thought to be partly responsible for the recent religious conflict.

Demographic trends. Nigeria, like other developing nations, has high birth and mortality rates, although since about 1950 there has been a considerable decline in the rate of infant mortality and an increase in life expectancy. There has consequently been a rapid growth in the population.

Internal migration

A considerable movement of population takes place within Nigeria. There has been a south-to-north movement of migrants who settled in the northern cities of Kano, Sokoto, Kaduna, Jos, and others, as well as a north-to-south movement of seasonal migrants from the Sokoto and Kano areas into the cacao-growing Yoruba areas. A larger number of people migrate from the Igbo and Ibibio areas and from the Niger Delta to the more industrialized and urbanized western states of Lagos, Oyo, and Ogun and to the western states of Ondo and Bendel, which are rich in agricultural resources. Many of these migrants work as labourers in the cacao- and rubber-producing districts or as tenant farmers.

Before the end of the civil war in 1970, many Nigerians migrated to work in Benin, Ghana, Equatorial Guinea, Cameroon, and Sierra Leone. The expulsion of aliens (mostly Nigerians) from Cameroon in 1967 and from Ghana in 1969, as well as the relative buoyancy of the country's economy, attracted foreign western Africans into Nigeria from about 1972. This trend was encouraged in 1978 by the establishment of the Economic Community of West African States, under which the free movement of citizens of member states is guaranteed. In the early 1980s, the downturn in the Nigerian economy and religious riots in which foreigners were allegedly involved prompted the government to reverse its immigration policy. In early 1983, about two million aliens were expelled from Nigeria and in 1985 another 700,000 were expelled. A small but increasing number of Nigerians emigrate to Great Britain, Germany, Canada, and the United States.

The economy. The Nigerian economy still exhibits colonial traits. One such trait is the coexistence of a modern market economy and a dwindling traditional economy that features the use of group and age-grade labour and of payments in kind. Government, federal and state, is the major employer.

Since independence the government has implemented four comprehensive development plans. Despite these, the great majority of the population is still engaged in farming; yet there exists a serious food deficit resulting in an increasing food import bill. A series of world oil price increases from 1973 produced rapid economic growth in transportation, construction, manufacturing, and government services; this led to a great influx of rural people into the larger urban centres. Agricultural production stagnated to the extent that Nigeria, once a major exporter of palm oil, peanuts, and cotton, became a net importer from about 1975. The rapid increase in population has also contributed to the continued low income per capita in spite of sizable oil revenues.

The indigenization decrees of 1972 and 1977, which stipulated an equity participation by Nigerians of 40 percent and 60 percent, respectively, in most economic ventures,

led to a considerable increase in the profits that accrue to Nigerians, especially from the manufacturing sector. Outright nationalization of industries is not contemplated in view of the dependence of some key industries on foreign equipment and personnel and the need to create an atmosphere attractive to foreign investment.

Resources. Nigeria has a variety of both renewable and nonrenewable resources, some of which have not yet been effectively tapped. Solar energy is probably the most extensive of the underutilized renewable resources, but it is likely to remain untapped as the vast reserves of natural gas produced along with crude oil have yet to be fully harnessed. Water power from the many rivers, another renewable resource, is not fully developed but provides much of the power used in industry and in homes. The main sources of hydroelectric power are the Kainji Dam, the Shiroro Dam, and the Jebba Dam power stations. Other smaller plants are in operation, and large hydropower stations are planned for Makurdi, Zungeru, and Mambilla.

The land, like the forests and fisheries of the country, is renewable if properly managed but can be rendered nonrenewable through careless exploitation. Nigeria has no shortage of arable land. There is an extreme shortage of farmland in the very densely settled districts of the southeastern states and around Kano, Katsina, and Sokoto, however, resulting in the large-scale migration of land-hungry Igbo, Ibibio, and Hausa people to other parts of the country. Access to farmland is restricted in some localities that appear to have abundant cultivable land, and, in the far north, the desiccation of the Sahel has severely limited the land area available for cultivation.

Minerals   The most important minerals are crude oil, natural gas, coal, tin, and columbite. Oil, first discovered in 1956, has since 1970 been the most important source of government revenue and foreign exchange. Most of the oil output comes from onshore fields in the Niger Delta, although an increasing proportion of the crude produced since 1975 comes from offshore locations. Large reserves of natural gas exist, but most of the gas produced as a by-product of crude oil has had to be flared for lack of a market. Gas is used to generate electricity at Sapele and Afam, and, since 1984, oil companies have been required to reinject into the ground some of the natural gas produced in the course of pumping crude oil. The earliest mineral extraction (since the early colonial period) was of tin and coal. Tin and columbite, an iron-bearing mineral that accompanies it, occur in the Jos Plateau, and coal is found in the Udi district of Anambra state and in parts of Kwara and Benue states. The coal reserves consist of low-quality bituminous coal, a third of which is located in Anambra state. Deposits of lignite, or brown coal, occur in Bendel, Anambra, and Imo states. There are iron-ore deposits in the Lokoja area, which is close to the Ajaokuta steel complex in the lower Niger Valley. Limestone occurs in many areas and is widely exploited for manufacturing cement and for use in the steel industry.

Agriculture, forestry, and fishing. About two-thirds of all Nigerians obtain a living from agricultural production. Most are small-scale farmers who produce food crops for home consumption, with a little surplus for sale, and who derive additional income from one or more cash crops and from the sale of local crafts. Farms are small, usually less than two and one-half acres (one hectare) in the south and about seven and one-half acres in the open grassland areas of the north. The continued dominance of the primitive hoe and matchet (machete) as farm implements and the shortage of farmland in some localities and limited access to land in others are among the factors that restrict the size of farmland cultivated per family. Overcropping, soil impoverishment, repeated damage by drought, and lack of investment capital have contributed to low productivity and general stagnation in agriculture. In the face of rapid population growth and an accelerating rate of urbanization, the food deficit continues to worsen.

Root crops—notably yams, taro, and cassava—are the main food crops in the south, while grains and legumes—such as sorghum, millet, cowpeas, and corn (maize)—are the staple crops of the drier north. Tree crops—notably oil palm, cocoa, and rubber—are the main industrial crops of the south, while peanuts (groundnuts) and cotton are produced in the north. As with staple food crops, the production of industrial crops is dominated by small-scale farmers. In the late 1980s only cocoa was exported, since the local demand for palm oil, peanuts, cotton, and rubber exceeds production.

The first major step taken by the government to halt the decline in industrial crop production was to disband in 1982 the produce marketing boards, which paid prices set by the government. Many farmers have since been motivated to cultivate tree crops, and the federal and state governments have established plantations of oil palm, rubber, and cocoa. Programs to alleviate the food shortage have featured the direct purchase and distribution of foodstuffs by government agencies and the production by government parastatals of various staples on large commercial farms. The Operation Feed the Nation program of 1976–80 sought to increase local food production and thereby reduce imports. Citizens were encouraged to cultivate any empty plot of land; urban dwellers were encouraged to garden undeveloped building plots. In 1980 this program was replaced by the more elaborate National Council on the Green Revolution, which has had little impact.

Livestock production has remained largely undeveloped during the mid-20th century. The nomadic cattle Fulani are still the main producers of beef cattle, although some of the cattle under the care of these nomads belong to settled farmers and city dwellers.

Nigeria's permanent forest reserves consist of savanna   Forests woodland (76 percent), tropical rain forest (20 percent), and swamp forest (4 percent). Outside the reserves, much of the forest cover has been destroyed through regular burning when preparing farmland or during hunting. Forest destruction is most complete in the very densely settled areas and in the drier savanna, where overgrazing, bush fires, and the great demand for fuelwood has prevented normal regeneration of plants on fallow land. Fuelwood (firewood and charcoal) is the main source of domestic fuel even in urban areas and accounts for about 95 percent of domestic consumption of forest products.

There are many large plantations of exotic species, such as gmelina and teak, established by the government to provide electric and telegraph poles and fuelwood. In the arid zone of Sokoto, Kano, and Borno states, forest belts have been established to help arrest the southward advance of the Sahara. Forest plantations have been established in many watersheds to protect water catchment areas of rivers and to reduce the incidence of soil erosion.

Fishing is the fastest-growing agricultural subsector and has assumed greater importance as a source of protein following the loss of thousands of livestock animals as a result of recurring drought in the Sahel since the early 1970s. The domestic catch supplies about 60 percent of the fish demand. Lake Chad and the coastal waters are the main sources of fish, but large quantities are caught every year in the pools of the seasonal rivers of the northern states; and there are opportunities to develop large scale fish farms in the reservoirs at Kainji Dam and a few smaller dams associated with multipurpose river-basin development projects.

Industry. Mining is the most important and the fastest-growing sector of the economy. Its share of the gross domestic product rose from about 1 percent in the 1950s to about 25 percent in 1977 because of the rapid increase in crude oil output. From an output of 9,000 tons in 1958, oil production increased to more than 19 million tons in 1966 and in 1979 the record level of 114 million tons was achieved. Two years after Nigeria joined the Organization of Petroleum Exporting Countries (OPEC) in 1971, a huge price increase occurred, more than doubling Nigeria's oil revenue from 1973 to 1974. Thereafter oil prices continued to rise, reaching a peak in 1980 before the price crash of 1981. There are oil refineries at Port Harcourt, Warri, and Kaduna.

Tin mining in the Jos Plateau started in 1905. Since 1962, when a smelting plant was built to produce tin ingots, tin has not been exported in its raw form. The production of tin ore and columbite has always been controlled by private companies. Production is by open-pit mining.

Coal mining began in 1915 and has always been under the direct control of the central government. In the oldest mines, located near Enugu, the coal is obtained from adits driven into the scarp slope of the Enugu cuesta. Production was restricted to Anambra state until 1968, when the mines near Enugu were closed because of the civil war; production then began at Okaba in Benue state.

Traditional industries carried out in homes or in makeshift workshops include the making of iron implements such as hoes and hatchets, door hinges, bolts, and dane guns (firearms of obsolete design, originally of European manufacture). Traditional soap- and salt-making workshops appeared in large numbers after the near collapse of the Nigerian economy in 1983, when most wage earners were unable to pay for factory made soap and imported table salt. Pottery making and wood carving are widespread, as are canework and the making of bags and mats from raffia.

The manufacturing sector is the second fastest-growing sector after mining. Revenue from mining has enabled the central government to embark upon such capital-intensive industries as the Ajaokuta and Aladja steel mills, pulp and paper mills at Oku Iboku and Iwopin, and petrochemical plants at Kaduna and Port Harcourt. Before the large increase in government revenue, large-scale manufacturing—dominated by the production of textiles, tobacco, beer, soft drinks, and cement—was controlled by foreign investors. The indigenization decrees have altered the ownership situation, although the management and effective control of most large factories are still in the hands of expatriate representatives of multinational corporations. The greatest weakness of this sector has been its dependence on foreign raw materials, a situation that changed in 1987 when the prohibition on importation of a wide range of raw materials forced local breweries to substitute sorghum and rice for barley and flour mills to process corn instead of wheat for bread. The highest concentration of large factories is in the Greater Lagos area. Each state capital has a number of large manufacturing industries, but a few major industries, such as the paper mills and the steel mills, are located in remote areas where new towns have grown up to serve the factories.

Finance. The naira is the basic unit of Nigerian currency. The main sources of government finance consist of direct taxes and revenue from a petroleum profits tax and from mining royalties. Unexpected and drastic fluctuations in oil prices since 1981 therefore created considerable difficulty in the implementation of the 1981–85 National Development Plan and in meeting recurrent government expenditures. Recurrent federal expenditures consist mainly of transfers to state governments, defense, general administration, health care, and education.

The increase in government revenues following the rise in oil prices in the early 1970s led to unprecedented expansion in education, in prestige projects, and in the misappropriation of public funds, resulting in a heavy public external debt and federally owed domestic debt. The servicing of the external debt since 1984, at a time when oil prices have remained low, has been a major strain on the management of the economy. In 1985 and 1986, for example, the country spent as much as 40 percent of annual export earnings to service foreign debts, leaving little for economic development.

The Central Bank, established in 1959, has branches in all the state capitals and provides guidelines to all commercial and merchant banks in the country. In 1976 all foreign banks were compelled to sell 60 percent of their shares to Nigerians.

Trade. The direction of domestic trade in staple foods is largely north and south between different ecological zones but also to the major urban centres. The southern states supply plantains, cassava, and fruit to the northern states, which in turn supply beans, onions, and vegetables to the southern states. Yams and potatoes from the middle belt are traded in the southern and the far northern cities. Livestock traded in the south comes mostly from the north, which relies on the forest belt in the south for kola nuts. There is a sizable trade in foodstuffs from the eastern states and Bendel to the urbanized Yoruba cultural area

of southwestern Nigeria. Women play a dominant role in the marketing of foodstuffs and manufactured goods. There are few department stores, and most of the food items and manufactured goods are sold in open market stalls and small neighbourhood shops.

There is very little trade between Nigeria and other African countries. The main markets for Nigerian exports—consisting mostly of crude oil, cocoa, palm kernel, timber, and tin ingots—are the United States, Britain, Japan, France, and Germany. Trade with the Soviet Union increased during the civil war in the late 1960s and continued until the dissolution of the U.S.S.R. in 1991. The main imports are consumer goods, nondurable goods, industrial raw materials, industrial and construction machinery, and passenger cars, most of which come from Japan and western Europe.

Before 1954, when consumer goods dominated the import list, Nigeria had a favourable balance of trade. The growth of imports in machinery and equipment following the granting of internal autonomy by Britain and low commodity export prices combined to create a trade deficit from 1955 to 1965. Thereafter Nigeria had a trade surplus based on revenue from crude oil exports. The structure of imports altered during the early 1970s, with capital goods and industrial raw materials accounting for about 70 percent of all imports by value. Reckless spending and fraud brought about a balance of payment deficit beginning in 1976. Improved earnings from oil and restrictions on imports the year before the return to civilian rule in 1979 reversed the unfavourable trend and resulted in a trade surplus in 1980. The resumption of projects in the new federal capital designate of Abuja contributed to a high import–export imbalance in 1982. By the end of 1983, when the military again intervened in Nigerian politics, the country had become virtually bankrupt, to the point where importers found it difficult to obtain letters of credit from foreign banks.

Transportation. The general pattern of transport is from north to south, running from the interior to the southern seaports. This pattern dates back to the colonial period, when raw materials were produced in the interior and shipped to Britain and other western European countries, which in turn supplied manufactured goods. The transport pattern also resulted from the fact that different agricultural products are grown in zones, or belts, running from east to west, so that the general direction of internal exchange trade is from north to south.

Nigerian roads fall into three categories: trunk A roads, which are maintained by the federal government and which link Lagos with all the state capitals; trunk B roads, which are maintained by state governments and which connect provincial capitals and other large towns with the trunk A system; and other roads, which are maintained by local governments, carry local traffic, and act as feeders to the trunk-road systems. All trunk A and most trunk B roads are surfaced; almost all other roads are dirt. The conversion of the Benin–Shagamu and the Port Harcourt–Enugu trunk A roads into four-lane divided highways was completed in 1981. The only expressway in the country, opened to traffic in 1978, runs between Lagos and Ibadan.

The traffic flow on the roads is greatest in the cacao belt of southwestern Nigeria, the peanut and cotton belt of the Kano–Katsina region, the Jos Plateau tin fields, and the palm belt of southeastern Nigeria. These areas are served by a dense network of all-weather roads. The relatively unproductive and sparsely settled areas of the middle belt, of the Cross River region, and of the Chad Basin have tenuous road links that carry only a few trucks a day.

Roads are now the most important means of transportation, but formerly the railroad was dominant. On several occasions Nigeria's railroads have proved incapable of transporting large cargoes of peanuts and cotton from the north. The slow speed of trains (which is attributed largely to the narrow gauge of the railroads), along with the unhygienic conditions of the coaches and poor quality service, has resulted in lack of patronage of the passenger services. By the 1980s almost all cargo and passenger transport was by road and air, and movement by rail had declined sharply. The railroad system has two single-track

main lines: the eastern line from Port Harcourt to Maiduguri and the western line from Lagos to Kano. Branch lines connect the western main line to Kaura Namoda, to Nguru, and to Baro on the Niger. Since 1960 tracks have been relaid with heavier rail to permit heavier axle loads and higher speeds, improvements in signaling have speeded rail movements, and steam engines have been replaced by diesel locomotives.

In spite of the downturn in the Nigerian economy in 1983 and the devaluation of the naira by more than 80 percent in 1986, the government in 1989 resuscitated the plan to extend existing rail lines. Provisions were also made for the rehabilitation of existing rail lines, and a new rail line between a steel complex and Itakpe was completed in the 1990s to facilitate the transport of iron ore.

The creeks and rivers were the first means of communication in Nigeria. The most important waterways are the Niger and Benue rivers, which still carry substantial quantities of goods. The Cross River is used to ship exports to Calabar, but, like other rivers in Nigeria, it is not navigable during the dry season. Passenger and cargo boats operate on the lagoons and on the many creeks along the Nigerian coast from Lagos to the Cross River.

The ports — Lagos and Port Harcourt, administered by the Nigerian Ports Authority since its establishment in 1954, are the main international seaports. Chronic congestion at these two ports was largely responsible for the authority's takeover in 1970 of the port installations and administration of the smaller ports of Warri, Sapele, Koko, and Calabar. The expansion of the Lagos port complex in 1978 and the modernization and expansion of facilities in the smaller ports resulted in excess capacity by 1980.

Almost all the state capitals are served by air transport supplied by Nigerian Airways. There are smaller airfields in some provincial cities and in the oil-producing areas of the Niger Delta and the Cross River estuary. Lagos and Kano handle most of the transcontinental traffic. Other international airports include those at Port Harcourt, Calabar, Maiduguri, and Sokoto.   (R.K.U.)

Administration and social conditions. *Government.* Nigeria officially became a republic in 1963. The constitution promulgated in 1979 created a system of government in which the president, who is directly elected, exercised power as the chief executive and head of state. It also provided for a National Assembly, which consisted of the Senate and the House of Representatives. After a military coup on Dec. 31, 1983, parts of the constitution were modified or suspended, the National Assembly was replaced by a Supreme Military Council (SMC), and military governors headed each state. Following another coup in 1985, the SMC was renamed the Armed Forces Ruling Council, a new post of vice president was created in 1990, and a Constitution Review Committee was established to revise the 1979 constitution. The constitution promulgated in 1989 made only minor revisions to the 1979 document—notably extending the president's term to six years—but the existing government was dissolved after a military takeover in November 1993, and the 1979 constitution was restored. A Provisional Ruling Council took control of the government, but by 1998 its chairman, Abdulsalam Abubakar, was preparing for a return to civilian rule. Elections for the National Assembly and the presidency were held in early 1999, and a new constitution was promulgated in May.

Under the constitution, the president is head of state and is elected to serve a four-year term. A vice president and cabinet ministers are nominated by the president. The National Assembly consists of the House of Representatives and the Senate. Each state elects 10 members to the House of Representatives (a total of 360 members) for four-year terms; the 109 members of the Senate are also elected to four-year terms, with three members coming from each state and one member from the Federal Capital Territory.

There are two tiers of government—state and local—below the federal level. Nigeria is divided into 36 states and the Federal Capital Territory at Abuja; the constitution also includes a provision that more states can be created as needed. The functions of the government at the local level were usurped by the state government until 1988, when the federal government decided to fund local government organizations directly and allowed them for the first time to function effectively.

The Nigerian legal and judicial system contains three codes of law: customary law, Nigerian statute law (following English law), and Sharīʿah (Islāmic law). Customary laws, administered by native, or customary, courts, are usually presided over by traditional rulers, who generally hear cases about family problems such as divorce. *Qāḍī*s (judges) apply Sharīʿah law based on the Mālikī Islāmic code; training for this system is done in special schools.

Judicial system

Nigerian statute law includes much of the British colonial legislation, most of which has been revised. State legislatures may pass laws on matters not included in the Exclusive Legislative List, which includes such areas as defense, foreign policy, and mining—all of which are the province of the federal government. Federal law prevails whenever federal legislation conflicts with state legislation. In addition to Nigerian statutes, English law is used in the magistrates' and all higher courts. Each state has a High Court, which is presided over by a chief judge. The Supreme Court, under the chairmanship of the chief justice of Nigeria, is the highest court.

Military service is voluntary with the minimum age requirement being 18. Nigeria's armed forces include army, navy, and air force contingents. Nigerian troops have participated in several international peacekeeping missions.

Education. Great Britain did little to promote education during the colonial period. Until 1950 most schools were operated by Christian missionary bodies, who introduced Western-style education into Nigeria beginning in the mid-19th century. The British colonial government funded a few schools, although government policy was to give grants to mission schools rather than to expand its own. In the northern, predominantly Muslim area, Western-style education was prohibited because the religious leaders did not want Christian missionaries interfering with Islām, and Islāmic education was provided in traditional Islāmic schools.

Before 1976, when the Universal Primary Education (UPE) plan began, primary education was free only in the states of Lagos, Oyo, Ogun, Ondo, Bendal (now Delta and Edo states), Sokoto, and Niger. The primary-school population dramatically grew once the UPE plan became compulsory. Secondary education has always been free to indigenes of most of the northern states, although not everyone has taken advantage of the opportunity. In the southern states free education at the secondary level began in 1979 in Lagos, Ogun, Oyo, Ondo, and Bendel states.

The growth of free education

Although federal and state governments have the major responsibility for education, local governments, Muslim groups, and prominent citizens may establish and administer primary and secondary schools. The civil war of 1967–70 caused a shortage of teachers, and hundreds of Indian and Pakistani teachers were recruited, especially in the educationally disadvantaged Muslim areas in the north. Most of these Asian teachers left Nigeria between 1986 and 1988. Federal government involvement with secondary education is largely restricted to the so-called unity schools, admission to which is based on a quota to ensure representation from all states. Most secondary schools, trade centres, technical institutes, teacher-training colleges, and colleges of education and of technology are controlled by the state governments.   (R.K.U./Ed.)

At the time of Nigeria's independence in 1960, there were only two postsecondary institutions: University College (Ibadan) and Yaba Higher College. Four more government-operated universities were established in the 1960s, one in each geographic region—the University of Nigeria, Nsukka (east); the University of Ife, now Obafemi Awolowo University (west); Ahmadu Bello University (north); and the University of Lagos (south). In the 1970s and '80s the government attempted to found a university in every state, but, with the growing number of states, this practice was abandoned. Nigeria has more than 50 universities and colleges throughout the country; most of the universities are federally controlled, and for all the universities and colleges the language of instruction is English. Attempts by individuals and private organizations,

including the Christian churches, to establish universities have been frustrated by the federal Ministry of Education. The university student population has continued to increase. A shortage of qualified teaching staff as well as inadequate financing and the slow pace of physical development of the campuses are major problems.

Health and welfare. The concentration of people in the cities has created enormous sanitary problems, particularly sewage disposal, water shortages, and poor drainage. Large heaps of domestic waste spill across narrow streets, causing traffic delays, while the dumping of garbage along streambeds constitutes a major health hazard and has contributed to the floods that often plague Ibadan, Lagos, and other cities during the rainy season. Many people die from malaria, waterborne diseases, cerebrospinal meningitis, and other preventable diseases.

Health conditions are particularly poor in the shantytown suburbs of Greater Lagos and other large cities, where domestic water supplies are obtained from wells that are often polluted by seepages from pit latrines. Rural communities also suffer from inadequate or impure water supplies. Some villagers have to walk as far as six miles to the nearest water point—usually a stream. Because people wash clothes, bathe, and fish (sometimes using fish poison) in the same streams, the water drawn by people in villages farther downstream is often polluted. During the rainy season, wayside pits containing rainwater, which are often dug very close to residential areas, are the main source of domestic water supply. Cattle are often watered in the shallower pools, contributing to the high incidence of intestinal diseases and guinea worm in many rural areas.

Medical and health services are the responsibility of the state governments, which maintain hospitals in the large cities and towns. There are specialized hospitals in most of the state capitals, each of which also has a university teaching hospital financed by the federal Ministry of Health. There are many private hospitals, clinics, and maternity centres. Medical services are inadequate, even in the five western states where a free health service scheme was introduced in 1979. Many hospitals do not have enough medical personnel, and drugs are scarce. Rural areas are the most deprived of services.

There is no health insurance scheme or social welfare system for all Nigerians. Most commercial firms and factories provide free medical services for their employees and, in some cases, for their immediate families as well. Civil servants are entitled to free medical care in government-financed hospitals. Most elderly Nigerians and the unemployed depend on the extended family, which serves as the traditional social welfare system.

Housing

Overcrowding in the cities has led to the spread of slums and the emergence of shantytown suburbs in most of the larger urban centres. Since there are only a few housing corporations, most houses are built by individuals, who, unable to obtain loans from either commercial or government mortgage banks, must rely on their savings for constructing houses. House rents have steadily increased in the major urban centres as people have migrated into the cities in search of jobs. A federal housing program, begun in 1980, provides for the construction of low-cost housing for low- and middle-income workers in the state capitals, local government headquarters, and other large towns.

Cultural life. Nigeria has a rich and varied cultural heritage, deriving from the different ethnic elements, as well as Arabic and western European cultural influences. Secret societies, such as Ekpo and Ekpe among the peoples of the southeast, were formerly used as instruments of government, while other institutions were associated with matrimony. According to the Fulani custom of *sharo* (test of young manhood), rival suitors underwent the ordeal of caning as a means of eliminating the less persistent grooms-to-be, while in Ibibio territory, girls were confined for several years in bride-fattening rooms before they were handed over to their husbands. These and other customs were discouraged by colonial administrators and missionaries. Some of the more adaptable cultural institutions have been revived since independence; these include, for example, the Ekpo and Ekong societies for young boys in parts of the southeast.

The Institutes of African Studies at the Universities of Ibadan and Ife have done much to reawaken interest in traditional folk dancing and poetry, as have the School of Fine Arts and the School of Drama at Zaria and Ibadan. With the establishment of radio and television stations in all state capitals, programs featuring traditional music and dance, folk operas, and storytelling are available in some 25 languages. Because writing became common only after 1900 (except in the Muslim north), and because few educated Nigerians showed any interest in folk traditions and local culture until the late 1960s, much of the country's culture is believed to have perished. Many ancient folk songs have been revived by popular singers who use modern musical instruments to produce sounds that villagers can hardly identify with the songs they inherited from their ancestors.

With a few exceptions, such as at Oron and Umuahia, national museums are restricted to large cities, usually state capitals. In Jos, the national museum and the zoo are a major tourist attraction. Movie theatres, showing mostly Indian and American films, are popular among the urban middle- and low-income groups.

For statistical data on the land and people of Nigeria, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.   (R.K.U.)

HISTORY

The peoples of Nigeria may be classified broadly into three linguistic groups: (1) the Niger–Congo; (2) the Saharan, principally Kanuri; and (3) the Chadic branch of Afro-Asiatic languages, notably Hausa, Margi, and related languages. The huge Niger-Congo group may be further subdivided into the Kwa subgroup, which is the largest and includes such languages as Yoruba, Edo, Ijo, Igbo, Igala, Idoma, Nupe, and Gwari; the West Atlantic subgroup, notably Fulani (Fulfulde); the Benue-Congo subgroup, previously called Semi-Bantu, which includes Tiv, Jukun, and several languages of the Cross River basin such as Efik, Ibibio, Anang, Ekoi; and Adamawa. While some peoples (such as the Fulani and the Tiv) are relatively recent immigrants, it is estimated on the basis of glottochronology that the bulk of Nigerian languages, specifically the Kwa subgroup, must have been spoken in roughly the same locations as they are now for some 4,000 years.

Early Nigerian cultures. *The Nok culture.* The oldest skeleton found by archaeologists in the Nigerian area, at Iwo Eleru, near Akure, in the southwest, has been dated to about 9000 BC. There are isolated collections of ancient tools and artifacts of different periods of the Stone Age, but the oldest recognizable evidence of an organized society belongs to the Nok culture (c. 500 BC–c. AD 200).

A series of accidental finds of fine terra-cotta figurines by tin miners on the Jos Plateau has revealed an ancient culture named after the village of Nok, where some of the most representative heads were found. It was a Neolithic culture that made the transition to the Iron Age. The people raised crops and cattle, and they seem to have paid particular attention to personal adornment, especially the hair. Distinctive features of Nok art include naturalism; stylized treatment of the mouth and eyes; relative proportions of the human head, body, and feet; distortions of the human facial features; and the treatment of animal forms. The spread of Nok-type figures in a wide area south of the Jos Plateau, covering southern Kaduna state southeastward to Katsina Ala, south of the Benue River, suggests a well-established culture that left traces still identifiable in the lives of the Numan and other peoples of the area today. Many of the distinctive features of Nok art can also be traced in later developments of Nigerian art at Igbo Ukwu, Ife, Esie, Benin City, and other places.

Igbo Ukwu. The Igbo Ukwu bronzes, which have been dated to about AD 900, reveal not only a high artistic tradition but also a well-structured society with wide-ranging economic relationships. Of particular interest is the source of the copper and lead, which may have been Tadmekka in the Sahara, for making the bronzes and of the coloured glass beads, which may have come from Venice. It is believed that the bronzes were part of the furniture of the burial chamber of a high personage, a priest-king, proba-

Features of Nok art

bly a forerunner of the Eze Nri, the king of Nri, a highly ritualistic monarchy surviving in northern Igbo territory. Nri may have been influenced by the Igala and seems in turn to have exercised considerable influence in earlier times not only on the Igbo but also on the Igala and other peoples of the Niger–Benue confluence.

Kingdoms and empires of precolonial Nigeria. *Kanem-Bornu.* While there is no continuous evidence to link the peoples of the Jos Plateau with the Nok culture, or the Eze Nri of today with Igbo Ukwu, the history of Bornu (Borno) antedates the 9th century, when Arabic writers in North Africa first noted the kingdom of Kanem, east of Lake Chad. The lake was then much larger, and its basin attracted populations and encouraged exchange. A pastoral group, ancestors of the Kanuri, was establishing a centralized state over those referred to collectively as the Bulala, or the Sao. Initially, the trading links were with Egypt and the Nile valley. There is some evidence of contact with the Christian kingdoms of Nubia before they were overrun by Islām, but it was Islām that gained a foothold in the ruling family of Kanem in the 11th century. From Kanem the rulers tried to dominate the areas south and west of the lake as well. By the 12th century, they were compelled by the attacks of the Sao to move the capital to the region west of Lake Chad and gradually lost control of most of the original Kanem.

For a long time, Bornu was the dominant power in the central Sudan, including much of Hausaland. The Bayajidda legend, concerning the mythical Middle Eastern ancestor of the Hausa, seems to suggest that the rise of a centralized political system in Hausaland was influenced from Bornu. Though the rulers of Bornu embraced Islām, the structure of the monarchy remained traditional, with the queen mother and other female officials exercising considerable power. The selection of the monarch, the coronation rites, and other bases of the royal authority were dictated by pre-Islāmic beliefs. The princes and other members of the royal family were granted fiefs and posted away from the capital to govern frontier zones, while people of slave origin were preferred for the royal guard and palace officials.

Hausaland. The Hausa occupy the northern plains beyond the Jos Plateau, west of Bornu, a crossroads open not only to Bornu but also to the states of the western Sudan, especially Mali and Songhai to the west; the trans-Saharan routes to the Maghrib; and various trade routes to the forest areas, through Nupe and Gwariland to Borgu, Old Oyo, and Benin. Perhaps because of this strategic location, the Hausa developed a number of centralized states—Daura, Katsina, Kano, Zaria, Gobir, and, later, Kebbi being the best-known—each with a walled city, a market centre, and a monarchical system of government. Islām, which was introduced from the Mali empire in 14th century, strengthened both the monarchical system and the commercial contacts. But it remained predominantly an urban religion until the beginning of the 19th century, and, even within the walled cities, some pre-Islāmic rites continued to feature in the ceremonies that sustained monarchical authority. There was considerable rivalry among the different states, not only about the area of agricultural land that each controlled but even more about the control of trade and trade routes. This lack of unity was both a cause and a result of periodic conquests from powerful neighbours, especially Bornu, Songhai, and, especially in the 17th and 18th centuries, Jukun.

Yorubaland and Benin. In the forested areas west of the Niger and south of Hausaland, it would appear that Ife, which flourished between the 11th and 15th centuries, emerged as the first major power. There some of the characteristic features of Yoruba culture emerged: a monarchical system based on city-states and nucleated villages; a pantheon of gods in which a few enjoyed widespread recognition, but with several variations locally; and Ifa divination with its corpus of sacred chants. Ife is best known for its potsherd pavements and the great artistry of its terra-cottas and bronzes, especially the naturalism of many of its bronze figures. The influence of Ife on surrounding states is attested from the fact that the monarchies in all the Yoruba states claim descent from Ife

as a way of establishing legitimacy, sometimes borrowing regalia from Ife to use in coronation rites and sometimes sending remains of deceased rulers to Ife for burial.

By the 15th century, monarchies in Benin and Old Oyo that derived from Ife were becoming stronger militarily and in the amount of land and peoples they controlled. Old Oyo was located beyond the forests. After more than a century of struggle with Borgu and Nupe, it established itself strategically as the emporium for exchanging goods from the north—rock salt, copper, textiles, leather goods, and horses—with products of the forests—kola nuts, indigo, parrots, and cowries. By the 17th century, it had built up a cavalry force with which it dominated people in western Yorubaland and in the dry gap to the coast.

When the Portuguese arrived in the kingdom of Benin in the 15th century, they found a monarchy with a complex structure of chiefs and palace officials presiding over a kingdom that was expanding in all directions. In time, Benin dominated not only the Edo-speaking peoples to the north and south but also the area eastward to the Niger and, along the lagoon, to Lagos and beyond. It also exerted considerable influence on eastern Yorubaland and maintained trading connections with Old Oyo. Benin art, beginning to flourish in the 15th century, was to maintain its vigour until the colonial period.

Igboland and the Delta states. Many Nigerian peoples did not develop centralized monarchical states. Of these, the Igbo are probably the most remarkable because of the size of their territory and the density of population. The characteristic decentralized pattern of life, in spite of the traditions of Nri, seems deliberate; monarchical institutions in such outlying parts as Asaba, Onitsha, and Aboh were due probably to the influence of the Igala and Benin. Igbo lineages were organized in self-contained villages or federations of village communities, with societies of elders and age-grade associations sharing various governmental functions. The same was true of the Ijo of the Niger Delta and peoples of the Cross River area, where secret societies also played a prominent role in administration. By the 18th century the needs of the overseas trade began to encourage the emergence of monarchical structures.

Initial Portuguese contacts were focused on Benin and Warri. By the 17th and 18th centuries, in the heyday of the slave trade, the delta city-states had become the principal outlets of the trade. Various coastal communities organized to take advantage of the trade as middlemen, so that they would not become its victims. Similarly, the Igbo, like the Edo and the Yoruba kingdoms, organized to get supplies of slaves to the coast. The deleterious effect of the trade on the society and the economy was felt everywhere, but in terms of loss of population, the ones who suffered most appear to have been the noncentralized peoples of the middle belt.

The Sokoto jihad. At the beginning of the 19th century, Islām was well established at all the major centres of the Hausa states and Bornu. The *etsu* (ruler) of Nupe had accepted Islām, and a few teachers and itinerant preachers were also known in parts of the Old Oyo empire. A group of Muslim intellectuals, mostly Fulani, led by Usman dan Fodio, were unhappy that in all these places the rulers allowed Islām to continue to be mixed with aspects of traditional religion and that nowhere was Islāmic law, the Sharī'ah, observed in full. After 20 years of writing, teaching, and preaching in Gobir and surrounding states, Shaykh Usman withdrew his followers to Gudu, where they formally proclaimed him *amīr al-mu'minīn* (commander of the faithful), pledged their loyalty, and prepared for war. In 1804 he called on his followers and all lovers of true Islām to rise up and overthrow the unjust rulers. He appealed to the masses of slaves and to the pastoral Fulani as oppressed people to join the revolt.

It indicates the degree of communication that existed at the time among different peoples in what was to become Nigeria that the call to jihad made in Gudu in the northwest corner had repercussions throughout the country. The amount of interaction along trade routes and rivers draining the northern plains to the Niger–Benue valley, through the delta, and across the coastal lagoons should not be underestimated. The call to jihad was answered

not only in the different Hausa states, such as Kano, Katsina, and Zaria, but also in Bornu, Bauchi, Gombe, and Adamawa, and eventually in Nupe, Ilorin, and other places where there were pockets of Fulani scholars.

Thus was created the caliphate, with its seat at the newly established town of Sokoto. Each emirate enjoyed autonomy but pledged loyalty to the *amīr al-mu'minīn* and made contributions for the upkeep of Sokoto. Disputes within or between emirates were referred to Sokoto for settlement by officials who traveled as often as possible to oversee developments. Usman himself retired in 1811 to concentrate on the intellectual direction of the movement, which followed the teachings of the Qādirī brotherhood and strict adherence to the Mālikī code of laws. His brother Abdullahi and his son Muhammad Bello carried on the jihad and laid the basis of administration. When Usman died in 1817, Muhammad Bello succeeded him as *amīr al-mu'minīn,* while Abdullahi as emir of Gwandu was given charge of the western emirates, notably Nupe and Ilorin. In this way, all the Hausa states, parts of Bornu, Nupe, Ilorin, and Fulani outposts in Bauchi and Adamawa were drawn into a single politico-religious system. The rulers of Bornu invited Shaykh Muhammad al-Amin al-Kānemī, a distinguished scholar and statesman who disagreed with the Fulani view that jihad was permitted against backsliding Muslims, to lead their forces in the defense of Bornu against the forces of the Fulani jihad. In the process Islām was revived in Bornu, and the old Seyfawa dynasty was eventually replaced by that of Shaykh Muhammad al-Kānemī.

The collapse of Old Oyo. Fulani intrusion into Ilorin was largely the result, rather than the cause, of the collapse of the Old Oyo empire. Deep-seated conflicts arose between the *alafin,* or ruler, and his chiefs, both provincial rulers and lineage chiefs and councillors at the capital. In spite of the external threat from the Fulani and others, the conflicts could not be resolved. Fulani ascendancy at Ilorin cut off the supply of horses to Old Oyo and made the capital untenable. Large groups of Oyo people had to migrate southward to establish a new capital at present-day Oyo and at other centres such as Ibadan and Ijaye. This pressure in turn pushed the Egba farther south to seek a new home at Abeokuta. The collapse of the Old Oyo empire unleashed a major redistribution of the Yoruba people and a series of Yoruba wars that lasted until 1886.

The coming of the British. The Sokoto jihad and the Yoruba wars stimulated the slave trade just when the British were actively trying to stop it. Slaves were traded for European goods, especially guns and gunpowder. The British encouraged the trade in palm oil in the Delta states, ostensibly to replace the trade in slaves. They later discovered that the demand for palm oil was in fact stimulating the internal slave trade, because slaves played the major role in collecting palm fruits, manufacturing palm oil, and transporting it to the coast by canoe or by human porterage. The palm oil trade was linked to the Sokoto jihad and the Yoruba wars because many warriors recognized the importance of slaves, not only as soldiers and producers of food to feed soldiers but also as producers of palm oil to trade for European Dane guns and other goods.

Many of the slaves exported in the 1820s and '30s were intercepted by the ships of the Royal Navy, emancipated, and deposited in Sierra Leone under missionary tutelage. Some of these began to migrate back from Sierra Leone in search of home and trade. They invited missionaries to follow them and, in the 1840s, made themselves available as agents for gaining entry not only for missionaries but also for British trade into such places as Lagos, Abeokuta, Calabar, and various locations on the Niger, such as Lokoja, Onitsha, Brass, and Bonny. In 1841, the British tried to settle some of them on a model farm in Lokoja, but the plan was aborted because of the high rate of mortality of European officials. It was also partly to protect them that the British shelled Lagos in 1851, expelled Kosoko, the reigning *oba,* and restored his uncle Akitoye, who appeared more willing to join in a campaign to abolish the slave trade. In 1861, to protect Akitoye's son and successor, foil Kosoko's bid to return, and secure a base for further activities, the British annexed Lagos.

The British were as yet unwilling to run the expense of maintaining an administration in Nigeria. To reduce expenses, Lagos was administered from Freetown in Sierra Leone, along with the Gold Coast forts, and later from Accra (in present-day Ghana). It was not until 1886 that Lagos became a separate colony. A consul was maintained at Fernando Po to oversee the lucrative trade in palm oil in the region called the Oil Rivers. Missionaries were active: Presbyterians in Calabar, the Church Missionary Society (CMS), Methodists, and Baptists in Lagos, Abeokuta, Ibadan Oyo, and Ogbomoso. The CMS took the initiative to pioneer trade on the Niger by encouraging a private businessman, Macgregor Laird, to run a monthly steamboat to western Africa so as to provide transportation to missionary agents and Sierra Leonean traders going up the Niger. In this way Bishop Samuel Ajayi Crowther of the CMS was able to establish mission stations at Onitsha, Lokoja, and Eggan, and later at Brass and Bonny.

By the 1870s, the Niger trade was becoming profitable, and a few French companies took notice. French Roman Catholic missionaries, established in Ouidah (Whydah), arrived in Lagos and considered missionary work on the Niger. The British responded to such evidence of rivalry. By the 1880s, they showed every sign of their determination to keep out all possible rivals including not only the French but also the Sierra Leonean pioneers of the Niger trade. At the Berlin West African Conference of 1884–85, the British defended the right of free navigation on the Niger; at the same time George Taubman Goldie bought out all French rivals and created a company, to which the British granted a charter, to control trade on the Niger and administer the immense territories of the Sokoto caliphate and Bornu. In addition, two other protectorates were declared, one over the Oil Rivers and the other over the hinterland of Lagos, to establish a claim that these areas were also British "spheres of interest."

Thereafter two developments should be noted. The first was the attempt to establish to Nigerian peoples that the British were no longer, as hitherto, negotiating for rights as traders and missionaries but rather were taking over control as rulers and overlords. Rulers that seemed to stand in their way, such as Jaja of Opobo and Nana of Itshekiri, were deposed and deported. While taking over Yorubaland in the guise of peacemakers between the warring parties, they decided to make an example of the Ijebu in 1892 by mounting an expeditionary force to demand that trade routes be kept open. A major force was sent to conquer Benin City in 1897. In that year the Royal Niger Company, having no force to dispose of, employed Frederick Lugard to assemble an army and assert the authority of the company in Bida and Ilorin.

The second development was that the boundaries of the two protectorates and the territories of the Royal Niger Company were difficult to define. There was rivalry between the Royal Niger Company and the Lagos Protectorate over the boundary between the emirate of Ilorin and the empire of Ibadan, just as there was tension between the Lagos and Oil Rivers protectorates over the boundary to be drawn between Benin and Yorubaland. The latter problem was eased in 1894 when both protectorates were merged into the Niger Coast Protectorate. The abrogation of the charter of the Royal Niger Company on Jan. 1, 1900, in return for wide mineral concessions eased the other problem. All the territories were now under British control, and the search for an identity had begun, first as Northern and Southern Nigeria, then with eventual amalgamation. All these were acts of the British, but they do not justify the claim that Nigeria was a creation of the British: it was the logic of the precolonial experience of the Nigerian peoples that dictated the wisdom of administering all the territories as one country.   (J.F.A.A.)

The 20th century. After the British government assumed direct control of the Royal Niger Company's territories, the northern areas were renamed the Protectorate of Northern Nigeria, and the land in the Niger Delta and along the lower reaches of the river was added to the Niger Coast Protectorate, which was renamed Southern Nigeria. Lagos remained the capital of the south, with Zungeru the new capital of the north. On Jan. 1, 1914, following

Margin notes:
Growth of palm oil trade

Southern Nigeria and Northern Nigeria

the recommendations of Sir Frederick Lugard, the two protectorates were amalgamated to form the Colony and Protectorate of Nigeria under a single governor-general resident in Lagos. Between 1919 and 1954, the title reverted to that of governor.

Indirect rule. As the first High Commissioner of Northern Nigeria, Lugard had been instrumental in subjugating the Fulani emirs. Some were deposed, some defeated in battle, and others collaborated. It was not until 1903 that the conquest of the emirates was complete. The mud-walled city of Kano was captured on February 3 and, after a vigorous skirmish at Kotorkwashi, the sultan's capital, Sokoto, fell on March 15. Lugard's proclamation following the appointment of a new sultan set out the principles of the administrative system subsequently institutionalized as "indirect rule." Essentially, local government was to be left in the hands of the traditional chiefs, subject to the guidance of European officers. Emphasis was placed on utilizing native institutions and on minimum interference with local customs. Although it had built-in contradictions, over the years the Nigerian system developed into a sophisticated form of local government, especially in the emirates, and under the title of "native administration" became the hallmark of British colonial rule in Africa. In Nigeria the major uprisings at Satiru in 1906, Abeokuta in 1918, and Aba in 1929, all involving grave loss of life, were to raise questions about its value as a model.

Further dislocation accompanied the outbreak of World War I. Locally this involved the immediate invasion of the German-held Kamerun by Nigerian forces, followed by a costly campaign that lasted until 1916. Later, Nigerian troops were sent to East Africa. (During World War II they again served in East Africa, as well as in Burma.) In 1922 Kamerun was divided under a League of Nations mandate between France and Britain. The latter administered its area within the government of Nigeria. After 1946, the mandated areas were redesignated as a UN Trust Territory.

Constitutional changes. Structurally, the constitutional amalgamation (it was not an administrative unification) of 1914 remained unchanged until the accession of the mandated areas in 1922 and the division of the Southern provinces into Western and Eastern in 1939. In 1954 the groups of provinces were renamed the Northern, Western, and Eastern regions as part of the reconstruction of Nigeria into a federal state.

In 1914 a legislative council was established, but its jurisdiction did not extend beyond the colony. A larger council was set up in 1922, with elected members (three from Lagos, one from Calabar). Its powers were limited and the Northern provinces remained outside the jurisdiction of the Nigerian Legislative Council. A radical change occurred in the quasi-federal Richards constitution of 1946. Each geographic group of provinces had its own house of assembly, with a majority of nonofficial (though not yet all elected) members. Two houses of chiefs were created, and there was a central legislative council in Lagos.

These changes failed to satisfy the groundswell of public demand for self-government. In particular, Nigerians resented the lack of discussion over the Richards constitution. A nationwide consultative process ensued, down to village level, culminating in a constitutional conference at Ibadan in 1950. The 1951 Macpherson constitution provided for a central house of representatives, but friction between the central and regional legislatures, related to the question of where supreme party authority lay, soon caused a breakdown.

The Lyttelton constitution

In 1954 Nigeria introduced the Lyttelton constitution, its third in eight years. This time, at the Nigerians' urging, it was a fully federal one, comprising the three geographic regions, the Southern Cameroons, and the Federal Territory of Lagos. Each region had a governor, premier, cabinet, legislature, and civil service, with the significantly weaker federal government represented in Lagos by a governor-general, bureaucracy, house of representatives, and senate. The post of prime minister was created in 1957 and was filled by Sir Abubakar Tafawa Balewa.

Internal self-government was granted to the Western and Eastern regions in 1957 but, at its request, not to the

Northern region until 1959. Northerners were fearful that their region might lose its claim to an equal share in the operation and opportunities of the federal government if it were not given time to catch up with the educationally advanced south. Among the problems calling for attention before the British would grant full independence was that of the minorities' fear of discrimination by a future government based on majority ethnic groups. After the Willink Commission reported on this issue in 1958, independence was granted on Oct. 1, 1960, under a federal constitution, with an elected prime minister and a ceremonial head of state. Following a UN-supervised referendum, the northern part of the Trust Territory of the Cameroons joined the Northern Region on June 1, 1961, while on October 1 the Southern Cameroons united with Cameroun to form the Federal Republic of Cameroon. In August 1963 the Mid-West region was created by dividing the Western Region, and on October 1 Nigeria became a republic. Nnamdi Azikiwe was the first president.

Independent Nigeria. After a honeymoon period, Nigeria's long-standing regional stresses of ethnic competitiveness, educational inequality, and economic imbalance again came to the fore in the controversial census of 1962–63. In the west the government fell apart in 1962. At the centre, a boycott over the federal election of 1964 brought the country to the brink of breakdown. The point of no return was reached on Jan. 15, 1966, when, after the collapse of order in the west following the fraudulent election of October 1965, a group of army officers attempted to overthrow the federal government. Prime Minister Balewa and two of the regional premiers were murdered. A military administration was set up under Major General Johnson Aguiyi-Ironsi, but his plan to abolish the regions and impose a unitary government met with anti-Igbo riots in the north. He was assassinated on July 29, 1966, and Lieutenant Colonel (later General) Yakubu Gowon came to power.

Gowon's attempt to hold a conference to settle the constitutional future of Nigeria was abandoned after the ethnic massacres of October 1966. A last-hope effort to save the country was made in January 1967 when the Eastern delegation, led by Lieutenant Colonel (later General) Odumegwu Ojukwu, agreed to meet the others on the neutral ground of Aburi, Ghana, but the situation deteriorated after differences developed over the interpretation of the accord. On May 27 the Eastern Region's consultative assembly authorized Ojukwu to establish a sovereign republic. At the same time the federal military government promulgated a decree dividing the four regions into 12 states, including six in the north and three in the east.

The civil war. On May 30, 1967, Ojukwu declared the secession of the three Eastern states under the name of the Republic of Biafra. The federal government interpreted this as an act of rebellion. Fighting broke out on July 6 and within weeks Gowon's so-called "police action" escalated into a full-scale war. In August Biafran troops crossed the Niger, seized Benin City, and were well on their way to Lagos before they were checked at Ore. Then federal troops entered Enugu and penetrated the Igbo heartland. The next two years were marked by stiff resistance in the shrinking Biafran enclave and by heavy casualties among civilians as well as in both armies, all set within what threatened to be a military stalemate. Peace-making attempts by the Organization of African Unity remained ineffective. Biafra began to earn recognition by African states and to secure aid for its starving population from international organizations. Then suddenly the conflict was over. Ojukwu fled to Côte d'Ivoire on Jan. 11, 1970, and on January 15 a Biafran deputation formally surrendered in Lagos.

General Gowon announced a program of reconstruction and reintegration. In 1974 he postponed the 1976 target date for a return to civil rule but was overthrown on July 29, 1975, by Brigadier Murtala Ramat Mohammed, who was assassinated on Feb. 13, 1976. It was left to Mohammed's successor, Lieutenant General Olusegun Obasanjo, to implement the revised program.

Shehu Usman Aliyu Shagari was installed as president of the Second Republic on Oct. 1, 1979. His regime ran

Formation of Biafra

into trouble, especially after the collapse of oil prices, and, although he was reelected in mid-1983, he was overthrown by the military on Dec. 31, 1983. Major General Mohammed Buhari's authoritarian Supreme Military Council was overturned by another coup (Nigeria's sixth in 20 years) when Major General Ibrahim Babangida became head of state on Aug. 27, 1985. Babangida's Armed Forces Ruling Council (AFRC) concentrated on economic reforms. Babangida promised a return to civilian rule, and in January 1993 he dissolved the AFRC and established a transitional government. (A.H.M.K.-G.)

However, the country's first civilian elections, in which Moshood Abiola was victorious, were annulled by the NDSC, and power was seized by General Sani Abacha. Again transition to civilian rule was promised, but Abacha became increasingly autocratic, jailing opponents (including Abiola) and stifling all opposition. The deadlock of economic stagnation and civil unrest was broken in June 1998 when Abacha suddenly died. Elections held in 1999 were won by Olusegun Obasanjo of the People's Democratic Party. He immediately set about undoing the damage of the Abacha regime. (Ed.)

For later developments in the history of Nigeria, see the BRITANNICA BOOK OF THE YEAR.

Sierra Leone

The Republic of Sierra Leone is a sovereign country bordered on the north and east by Guinea, on the south by Liberia, and on the west by the Atlantic Ocean. One of the smaller African countries, it has an area of 27,699 square miles (71,740 square kilometres). By African standards, the population of Sierra Leone is large in relation to the country's size. The capital, Freetown, commands one of the world's largest natural harbours.

PHYSICAL AND HUMAN GEOGRAPHY

The country owes its name to the 15th-century Portuguese explorer Pedro de Sintra, the first European to sight and map Freetown harbour. The original Portuguese name of Serra Lyoa (Lion Mountains) referred to the range of hills that surrounds the harbour.

Although most of the population is engaged in subsistence agriculture, Sierra Leone is also a mining centre. Its land yields diamonds, gold, bauxite, and rutile (titanium dioxide). Urbanization has resulted in the gradual depopulation of the rural areas and the growth of a jobless population in the cities.

The land. *Relief.* The country can be divided into four distinct physical regions. The coastal swamp region extends along the Atlantic for about 200 miles (320 kilometres). It is a flat, low-lying, and frequently flooded plain that is between 20 and 40 miles wide and is composed mainly of sands and clays. Its numerous creeks and estuaries contain mangrove swamps. Parallel ridges, often separated by silting lagoons, are common and sometimes form the actual coast. The Sierra Leone Peninsula, which is the site of Freetown, is a region of thickly wooded mountains that run parallel to the sea for about 25 miles. The Peninsula Mountains rise from the coastal swamps and reach 2,913 feet (888 metres) at Picket Hill.

Inland from the coastal plain is the interior plains region. In the north it comprises featureless grasslands (savanna) that are known as "Bolilands" (*boli* being a Temne word for those lands that are flooded in the rainy season and dry and hard in the dry season and on which only grass can grow). In the south the plains comprise rolling wooded country where isolated hills rise abruptly to more than 700 feet. The interior contains a variety of landforms ranging from savanna-covered low plains to rocky scarp and hill country. The plateau region, encompassing roughly the eastern half of the country, is composed mainly of granite with a thick laterite (iron-bearing) crust; to the west it is bounded by a narrow outcrop of mineral-bearing metamorphic rocks known as the Kambui Schists. Rising above the plateau are a number of mountain masses; in the northeast the Loma Mountains are crowned by Mount Loma Mansa (Mount Bintimani) at 6,390 feet, and the Tingi Hills rise to 6,079 feet at Sankanbiriwa Peak.

Drainage and soils. The country's drainage pattern is dense. Numerous rivers rise in the well-watered Fouta Djallon highlands of Guinea and flow in a general northeast to southwest direction across Sierra Leone. Their middle courses are interrupted by rapids that restrict navigability to only a short distance inland. River levels show considerable seasonal fluctuations.

The drainage system has nine major rivers and a series of minor coastal creeks and tidal streams. From north to south, the principal rivers are the Great Scarcies, Little Scarcies, Rokel (known in its lower course as the Sierra Leone River), Gbangbaia, Jong, Sewa, Wanje, Moa, and Mano. The Great Scarcies and Moa form portions of the border with Guinea, while the Mano forms much of the country's frontier with Liberia.

In most areas, the dominant soils are of the weathered and leached lateritic (iron-bearing) type. Red to yellow-brown in colour, they contain oxides of iron and aluminum and are acid. Kaolin (china clay) is important in some areas, and when cultivated a light, readily workable, free-draining soil results, whose productivity depends largely on the nutrients provided from the vegetation previously cleared and burned. In the coastal plains lateritic soils developed on sandy deposits are agriculturally poor, but those derived from basic igneous rocks are somewhat better. Swamp soils occur over large areas on the coastal plains where drainage is a problem. In coastal and estuarine areas where mangrove is the natural vegetation, productive soils can be acquired by clearance, but careful water control is sometimes needed to prevent toxicity. At the foot of the main escarpment, on the Sula Mountain plateau, and elsewhere an iron-rich laterite crust forms a surface that is intractable for agricultural production.

Climate. The climate is tropical and is characterized by the alternation of the rainy and dry seasons. Conditions are generally hot and humid. Mean monthly temperatures range from 77° F (25° C) to 83° F (28° C) in low-lying coastal areas; inland the range may be from 73° F (23° C) to 82° F (28° C). In the northeast, where extremes of temperature are greater, mean daily minimums fall to 56° F (13° C) in January, and mean daily maximums rise to 90° F (32° C) in March. During the rainy season, from May to October, humid air masses from the Atlantic dominate. The sky is cloudy, the winds are southwesterly, sunshine is minimal, and rain falls almost daily, especially during July and August. Precipitation is greater on the coast than inland; as much as 200 inches (5,080 millimetres) of rain falls annually on the Peninsula Mountains, while the northeast receives about 80 inches a year.

The dry season, from November to April, is characterized by the dry harmattan that blows from the Sahara. The rainy season tends to have cooler daily maximum temperatures than the dry season by about 10° F (6° C).

Plant and animal life. The distribution of plants and animals has been influenced by such factors as relief and soil types and, perhaps more importantly, by farming methods. Remnants of the extensive original forest cover remain in the Gola Forest reserve in the southeastern hill country near the Liberian border. Secondary forest is now dominant, and valuable timber species, such as African mahogany (*Khaya* species) and African teak, that were common in the original forests are now rare. The secondary forest is characterized by other tree species, such as the fire-resistant palm tree, a valuable source of palm oil and kernels.

The prevalence of savanna vegetation increases to the north as rainfall decreases. The savannas owe their present extent and character largely to the erosion produced by farming, grazing, and the use of fire. There are some small areas of climax savanna (a closed area of broad-leaved, low-growing trees) and tall tussocky grasses. Other savannas are derived from forest and are characterized by fire-resistant savanna trees with tall grasses. Tracts of tall-grass savanna also occur. Remnants of mangrove swamps constitute the main coastal vegetation community, especially in the saline tidal areas of river estuaries. Piassava, a kind of raffia palm, is common in the swamps of the south.

Large game animals, such as elephants, leopards, lions, hyenas, and buffalo, are rarely seen. Chimpanzees and various species of monkeys are common in the forest

zones, while tiger cats, porcupines, antelope, and bushpigs are more generally distributed. There is a wide variety of insects, including the malaria-carrying mosquito and the tsetse fly. Hippopotamuses, crocodiles, manatees, and alligators occupy the rivers. The coastal waters, estuaries, and rivers, such as the Sierra Leone and Sherbro, also contain a wide variety of fish, such as tuna, barracuda, and mackerel, as well as lobsters and sharks. Bird life includes parrots, owls, kingfishers, green pigeons, African magpies, vultures, and many other species.

Settlement patterns. Villages of about 35 buildings and 300 inhabitants dominate the rural landscape. Modernization is slowly altering the traditional pattern of rural settlement; the old circular village form, with a tight cluster of houses, is rapidly yielding to the linear village along a road or the regular gridiron pattern with adequate spacing between houses. Economic activity still centres largely around rice farming. The extended family provides farm labour for both rice farming and cash crop production. Fishing is becoming increasingly important. The raising and herding of cattle is largely confined to the north. The small shopkeeper is typical of the villages, as are the tailor and carpenter. Traditional crafts, such as metalworking, cloth dyeing and weaving, and woodworking, are rapidly disappearing with the increased importation of cheap manufactured goods.

Urban development

Except for Freetown, the development of large towns occurred only after World War II. Because of the incipient nature of urbanism, functional specialization is rudimentary, the most prominent feature being the daily market of petty traders, the majority of whom are women.

Freetown is a long, narrow city. Central Freetown—the administrative and commercial hub of the city—houses government buildings and embassies, the law courts, hotels, and the Roman Catholic and Anglican cathedrals. Eastern Freetown is mainly residential, with retail trading concentrated along major roads; there are also a few impressive mosques in the area. Farther east is the port area. Western Freetown is functionally similar to the east; it also contains the nation's main stadium, the central prison, and administrative offices. On Mount Aureol, overlooking the city, is Fourah Bay College, black Africa's first institution of higher learning.

Bo, located in the southeast, is the second largest town. An early administrative and educational centre, it has shown rapid expansion and has engulfed several surrounding villages. Commerce and retail trade are located in the centre of town near the important daily market. Its role as an educational centre has increased steadily, and Bo now contains many schools, including the Bo Government Secondary School, founded in the early 20th century.

Other important towns include Kenema, east of Bo, which has grown as a result of diamond mining, and, in the north, Makeni, a provincial capital and major commercial centre. Mining has also been important to Koidu, Sefadu, Yengema, and Jaiama in the east and Lunsar in the north. Port Loko, Kabala, Bonthe, Moyamba, Kailahun, Kambia, Pujehun, and Magburaka are administrative centres with retail trading and produce marketing.

The people. There are about 18 ethnic groups that exhibit similar cultural features, such as secret societies, chieftaincy, patrilineal descent, and farming methods. The Mende, found in the east and south, and the Temne in the north form the two largest groups. Other major groups include the Limba, Kuranko, Susu, Yalunka, and Loko, in the north; the Kono and Kissi, in the east; and the Sherbro, in the southwest. Minor groups include the coastal Bullom, Vai, and Krim and the Fulani and Malinke (Mandingo), who are immigrants from Guinea concentrated in the north and east. The Creoles—descendants of free blacks who colonized the coast in the 19th century—are found mainly in the Western Area and Freetown. Ethnic complexity is further enhanced by the presence of Lebanese and Indian traders in urban centres.

Linguistic patterns

Krio, a language derived from English and a variety of African languages, is the mother tongue of the Creoles and the country's lingua franca. Among the indigenous languages, the Mande group is the most widespread; it includes the Mende, Kuranko, Kono, Yalunka, Susu, Vai,

and Malinke languages. The Mel group, which is similar to the Bantu languages of Central and East Africa, includes the Temne, Krim, Kissi, Bullom, Sherbro, and Limba languages. English, the official language, is used in administration, education, and commerce. Arabic is used among Lebanese traders and adherents of Islām.

About half the population practices a variety of animist religions. More than one-third of the people are Muslims, and the rest are Christians.

The economy. Private capital dominates mining concerns, commerce, and banking. European, Lebanese, and Indian interests are predominant, and participation by Sierra Leoneans is small. The public sector features the Sierra Leone Produce Marketing Board (SLPMB), which has a monopoly on cash crops, and other public corporations, such as that of road transport, which is entirely owned by the government. Various inefficient parastatals were privatized in the 1980s. Government revenue is derived from direct and indirect taxes. In addition to import and export taxes, the government can also rely on company, excise, income, and mining taxes for revenue. The government's revenue from trade has been undermined by the growth of smuggling of diamonds and agricultural produce.

There were growing economic difficulties in the 1980s, including a heavy external debt burden, escalating costs of food and fuel imports, and erratic mineral export production. Substantial devaluations of the national currency, the leone, occurred, and a series of International Monetary Fund-supported economic stabilization programs were initiated to address these problems.

Resources. Mineral resources are fairly well distributed and include diamonds, chromite, and reserves of rutile that are among the world's largest. There are iron ore reserves, but these are no longer commercially mined. Other minerals include bauxite, columbite (a black mineral of iron and columbium), pyrochlore, gold, platinum, and monazite. Major concentrations of those minerals have been found in the southern plateau region.

Mineral resources

Forest covers more than one-fourth of the country, the most important area of which is the Gola Forest Reserve, a tract of primary tropical rain forest, near the Liberian border. Biological resources include large herds of tsetse-resistant Ndama cattle. The coastal waters provide rich fishing grounds for shad, herring, snapper, tuna, shrimp, and lobster. The hydroelectric power potential of Sierra Leone's deeply incised river valleys is appreciable.

Agriculture and forestry. Agriculture is carried out largely by traditional methods. More than three-fifths of the population engages in production for the domestic and export markets. Rice, the main food crop, is widely cultivated on swampland and upland farms. Swamp-rice cultivation is concentrated in the lower reaches of river basins, of which the Scarcies is the most important. Efforts are being made to reduce upland-rice farming with its attendant soil erosion in favour of swampland farming with its superior yields. Other food crops include millet, peanuts (groundnuts), cassava, sweet potatoes, and oil palms. Vegetable gardening is important around the major urban centres, where markets are available to farmers. In the 1970s, the government attempted to improve agricultural productivity through integrated development projects funded by the World Bank. However, the country has become a net food importer, especially of rice.

The major cash crops are palm kernels, cocoa, coffee, piassava, and ginger. Production is carried out entirely by small-scale farmers. Timber (which includes *Guarea cendrata,* a cedar-scented, pink, mahogany-type wood, and the *Lopjara plata* variety *procera,* or red ironwood) is produced for the domestic market; there are major sawmills located in the Gola Forest; the main furniture factory is in Kenema.

Industry. Mining is the most important industry in terms of employment in the modern sector and in exports and is second only to agriculture in its contribution to the national economy. Diamonds are mined by the National Diamond Mining Company (Diminco), by a few private companies, and by vast numbers of private prospectors. Mining methods range from mechanical grab lines with

The mining industry

washing and separator plants to crude hand digging and panning. About half of the diamonds are gem stones found in river gravels, especially along the Sewa-Bafi river systems. Official exports of diamonds have declined dramatically since the 1960s owing to extensive smuggling and the depletion of reserves. There have been several changes in the ownership of Diminco, and investment has been sought for deep-mining of diamonds as the alluvial sources are depleted.

The privately owned Sierra Leone Development Company (SLDC) mined iron ore at Marampa from 1935 to 1975. In 1981 the government reopened the mine at Marampa but soon encountered financial difficulties and suspended operations in 1985. During 1963 the Sierra Leone Ore and Metal Company (Sieromco) opened opencast bauxite mines at Mokanji Hills. The ore is shipped to Europe for reduction and refining into aluminum. Rutile is found in the southwest; in 1965 rutile production was begun, and production and prospecting activities boomed in the 1980s.

Industrialization is restricted largely to import substitution. Manufacturing is concentrated in Freetown, and production is mainly of consumer goods, such as cigarettes, sugar, alcoholic beverages, soap, tires, textiles, mineral fuels, and lubricants. Although factories are small and employ fewer than 1,000 workers each, their role in economic diversification is important. In the provinces industries are concerned exclusively with the processing of agricultural and forest produce, such as rice, timber, and palm oil. Traditional industries, such as fish curing and leatherwork, continue.

Electricity is generated primarily by thermal plants, which are supplemented by a few small hydroelectric installations.

Finance and trade.   The Bank of Sierra Leone is the nation's central bank; it issues currency, maintains external reserves, and acts as banker and financial adviser to the government. The National Development Bank is charged with providing finances to investors within the country. The Sierra Leone Commercial Bank provides credit and technical assistance to farmers. Post Office savings banks are found in all main towns, and there are also various kinds of thrift and credit societies.

Foreign trade has expanded substantially since independence, although its character still reflects the colonial nature of the economy. An excessive reliance is placed upon a few primary products, most of which go to the United Kingdom, the United States, and western Europe. Minerals and agricultural products account for the bulk of exports. Imports, however, have become more diversified; they include machinery, textiles, vehicles, fuel, and food products.

Transportation.   A government railway was completed in 1916 as a means of opening the country to commerce and ensuring effective British occupancy. The railway was phased out by 1975, however.

A road network, originally developed as a feeder system to the railway, has become the principal transport carrier. The network is dominated by a series of highways radiating from Freetown to inland urban centres. The government launched a long-term program in the late 1980s to modernize the road system to meet the needs of rapidly expanding traffic. In addition, road links with Conakry, Guinea, and Monrovia, Liberia, were to be improved.

Inland waterways carry a considerable volume of mineral ores, piassava, and food products. Launches and sailing boats are important, especially on the southern route to Bonthe and the northern route to the Great and Little Scarcies. Freetown is the country's principal port. Its facilities handle all imports and agricultural exports. Specialized ports include Niti, which handles all bauxite and rutile exports, and Bonthe, which exports agricultural products.

The international airport of Lungi is situated on the north bank of the Sierra Leone River opposite Freetown. It can accommodate commercial jets and a large annual volume of traffic. Domestic air transport is limited.

Administration and social conditions. *Government.* The constitution of 1971 made Sierra Leone a republic within the Commonwealth. Adoption of the constitution

Marginal notes (left column):
Financial services

Port facilities

of 1978 created a one-party republic based on the All-People's Congress; the head of state, or executive president, was elected by delegates of the All-People's Congress, and there was a House of Representatives. Mounting political pressures and violence resulted in the adoption of a new constitution in 1991 that established a multiparty system. However, a violent military coup d'état in April 1992 installed a National Provisional Ruling Council (NPRC) and a new head of state. The NPRC subsequently named a cabinet and ordered the dissolution of the House of Representatives and the suspension of the new constitution and all political activity. The NPRC was reconstituted as the Supreme Council of State, and the cabinet was replaced by a council of secretaries in July, establishing stringent military rule.

The country is divided into four administrative units—the Western Area, which was the former Crown Colony of Sierra Leone, and three provinces (the Northern, Eastern, and Southern provinces), which were the former Protectorate of Sierra Leone. The Western Area includes the capital of Freetown. Northern Province is divided into five districts, Southern Province into four districts, and Eastern Province into three districts.

The districts are subdivided into some 148 chiefdoms, which are controlled by paramount chiefs and chiefdom councillors. The chiefdoms are further divided into sections and villages. The chiefs are hereditary rulers whose local powers have been largely superseded by those of officials of the central and local government. Their influence remains important, however, particularly in matters of traditional culture and justice.

In addition, there are district councils, which in some cases override the chiefdom administrations. The councils deal largely with local matters and are under the indirect control of the central government. Town councils also have been established in the larger provincial towns of Bo, Kenema, Makeni, Koidu, and Bonthe.

The laws of Sierra Leone follow the pattern of British law. Until 1971 the framework of the courts was equally similar, and the final court of appeal was the Privy Council in London. Since the adoption of a republican constitution, however, the highest court is the Supreme Court, headed by a chief justice.

There are local courts that take account of indigenous laws and customs, Magistrates' Courts administering the English-based code, a High Court, and a Court of Appeal. There are presiding officers in the local, magistrate, and juvenile courts who are not qualified lawyers but who are citizens of wide experience. The attorney general is also the minister of justice.

Education.   Education in Sierra Leone is offered in private and government-sponsored schools; it is not compulsory. There are primary schools for children from ages five to 12, secondary schools that also offer a seven-year pro-

Marginal notes (right column):
Local government

gram, technical institutes, and several vocational schools, trade centres, and teacher-training colleges in the country. The University of Sierra Leone consists of Fourah Bay College, founded in 1827, and Njala University College, founded in 1963.

Health and welfare. Most health and welfare services are provided by the central government. There are also a few hospitals belonging to religious societies and mining companies and private doctors. Every district in the interior has at least one hospital. The major hospitals with specialist facilities are in Freetown and Bo.

The Public Health Section controls port and airport sanitation, schemes for the control and eradication of malaria and other infectious or endemic diseases, and the sanitation of Freetown. In other areas sanitation is under the control of district health authorities and town councils supervised by doctors who are appointed by the central government.

Variety of housing

There is a fascinating variety of housing in the interior districts, depending on the availability of materials. Roofs are made of grass in the savanna region and of bamboo in the forest areas. Walls may be circular or rectangular and constructed of dried mud bricks, palm fronds, or, more generally, lattice pole work filled with mud and coated with clay or chalk. There is usually a veranda or shaded porch. In most villages and towns along the roads, houses are roofed with corrugated zinc and the walls constructed of cement. In Freetown and Bonthe, some houses remain that were built of wood or laterite stone in a Brazilian or Victorian Colonial style and roofed with slate.

Cultural life. The most outstanding feature of the country's cultural life is its dancing. The Sierra Leone Dance Troupe is internationally known. The different communities of the nation have their own styles of costume and dance. In addition, certain closed societies, such as the Wunde, the Sande (Bundu), and the Gola, have characteristic ceremonial dances. A wide range of agility, gracefulness, and rhythm is displayed; in addition, there are elements of symbolism in most of the dances. Drums, wooden xylophones (called balaphones), and various stringed instruments provide the musical background.

The Poro society for men and the Sande society for girls play an educational role in village culture.

The Vai script has the distinction of being one of the few indigenous scripts in Africa. Some of the local languages are written in European script, but a few, especially in the Muslim areas in the north, have been transcribed into Arabic.

Handicrafts. The carving of various wooden masks in human and animal figures for the dances is especially advanced in the southern region. The Sande mask worn on the head of the chief dancer during the ceremony attending the reappearance of the female initiates from their period of seclusion is perhaps the most well-known carved figure in Sierra Leonean art. It is a symmetrically stylized black head of an African woman with an elaborate plaited pyramidal coiffure adorned with various figures and with a facial expression of grave dignity and beauty.

Ivory figures are characteristic of the Sherbro, Bullom, and Temne peoples of the coastal and northern regions. Fine examples of these figures, which were bought or commissioned by Portuguese traders during the 16th century, are still extant. There are also steatite human figures, sometimes distorted, called *nomoli,* or, in wooden form, *pomtan* (singular, *pombo*), which certainly date earlier than the 16th century and were used probably for ancestor worship or fertility rites. At present, they are used for ceremonies to ensure abundance of crops.

Containers or rattles are carved from gourds and are decorated with intricate geometric patterns that are burned into them.

The weaving and dyeing of cloth

The weaving of blue or brown cloth of thick texture with linear designs is carried out in the southern and eastern regions by the Mende and the Kono. The cloth is made into coats for men or wrapped around as a lower garment by women and is also used as a bedspread. In the north, among the Temne, imported cotton or satin is dyed with indigo, the red juice of the kola nut, or imported dyes into beautiful patterns by tie-dyeing. In the west, baskets

are made with dyed raffia, and patterned slippers are fashioned from dyed wool.

Painting and literature. There is an active school of modern artists who are trained in Europe and the United States and whose paintings have been exhibited locally and abroad. Olayinka Burney Nicol, Hassan Bangura, John Vandi, Koso Thomas, and Gladys Metzger are among the best-known artists of Sierra Leone.

School texts, information bulletins, and collections of folktales are produced in indigenous languages such as Mende and Temne. There has been a literary tradition in Freetown since the 19th century. One of the most prolific writers was James Africanus Beale Horton, who wrote books and pamphlets on politics, science, and medicine while he was a medical officer in the British army between 1857 and 1871.

There were also 19th-century works on exploration by such Sierra Leone Africans as Samuel Crowther, a bishop of the Anglican Protestant faith, and another clergyman, John Cristopher Taylor. Sierra Leone is represented in most anthologies of African- and English-language poetry and short stories. In addition, the modern novels and short stories of Sarif Easmon, William Conton, and Eldred Jones give a vivid picture of modern life in the country.

The Sierra Leone National Museum in Freetown contains historical, ethnographic, and archaeological collections. Fourah Bay College and Njala University College both have libraries; the former houses the public archives.

For statistical data on the land and people of Sierra Leone, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.   (D.S.H.W.N./S.M.S.)

HISTORY

Early history. Archaeological findings show that Sierra Leone has been inhabited for thousands of years. Traditional historiography has customarily presented it as peopled by successive waves of invaders; but the language pattern suggests that the coastal Bulom (Sherbro), Temne, and Limba have been in continuous settled occupation for a long time, with subsequent sporadic immigration from inland by Mande-speaking peoples, including Vai, Loko, and Mende. They organized themselves in small political units—independent kingdoms or chiefdoms—whose rulers' powers were checked by councils. Secret societies, notably the Poro society, also exercised political power as well as instructing initiates in the customs of the country.

Muslim traders brought Islām, which became firmly established in the north and subsequently spread through the rest of the country.

Portuguese voyagers gave the name Serra Lyoa (Lion Mountains), later corrupted to Sierra Leone, to the mountainous peninsula at the mouth of the Rokel River where, from the 15th century onward, European traders congregated near the site of modern Freetown under the protection of African rulers, who welcomed them for the commercial opportunities they provided, exchanging imported manufactured goods for ivory and slaves to be employed across the Atlantic.

A group of freed slaves arrived in Sierra Leone from England in 1787 to form a settlement. It failed but was revived by a commercial company, the Sierra Leone Company, sponsored by English opponents of the slave trade. Black settlers who had liberated themselves from American slavery were brought over from Nova Scotia and built a new settlement, named Freetown. "Maroons," free blacks from Jamaica, were also brought in. These settlers were English-speaking, and many were literate and Christian.

After the British Parliament made the slave trade illegal in 1807, the British government took over the settlement (Jan. 1, 1808) as a naval base against the slave trade and as a centre to which slaves, captured in transit across the Atlantic, could be brought and freed. Between 1807 and 1864, when the last slave ship case was adjudicated in the Freetown courts, the British Navy brought in more than 50,000 "recaptives." Drawn from all over western Africa, these heterogeneous people lacked any common language or culture. The government therefore introduced a deliberate policy of turning them into a homogeneous Christian community. Protestant missionaries, along with the black

British rule

pastors of Freetown churches, worked with such success that within a generation the policy was virtually fulfilled. The (Anglican) Church Missionary Society founded an institution to train teachers and missionaries, Fourah Bay College, which was affiliated to the University of Durham, England, in 1876. The Society also opened boys' and girls' secondary schools.

The recaptives and their children, known as Creoles (today usually rendered Krios), prospered as traders, and some entered the professions, qualifying in Britain as doctors and lawyers. Thus they formed an educated West African elite.   (C.Fy.)

Colony and protectorate. During the 19th century the area around the coastal settlements was drawn increasingly into the British economic sphere. There was a market in Britain for shipbuilding timber, and most of the accessible forest trees in the coastal country were felled, altering the environment irrevocably. There was also a European market for vegetable oils, and unprocessed palm produce and peanuts were supplied in return for imported manufactures. Rulers fought for control of the trading centres and built up larger territories for themselves.

The colonial government made treaties of friendship with neighbouring rulers and gradually acquired jurisdiction over the coastline. At the period of the European partition of Africa, frontiers were delimited with the neighbouring French and Liberian governments, and a British protectorate was proclaimed in 1896 over the area within the frontier lines, though the original colony retained its status. To raise revenue to pay for administration of the protectorate, a hut tax was imposed. The ruling chiefs, who had not been consulted about the protectorate, objected, and a revolt broke out in 1898 under Bai Bureh. It was suppressed by the end of the year. There were no further large-scale armed risings against the British.

In the protectorate the chiefs ruled under the supervision of British district commissioners. Innovation was discouraged, and little was done to extend education. In the colony many Creoles had held senior official posts in the 19th century, but after the protectorate was assumed they were gradually removed from office, replaced by British administrators.

Independence. After World War II the British government gave in to nationalist demands in Sierra Leone. The small Creole minority hoped to entrench their rights politically, but the 1951 constitution gave control to the majority. The government elected under it was led by Milton (later Sir Milton) Margai, leader of the Sierra Leone People's Party (SLPP), a predominantly protectorate party. During the 1950s parliamentary institutions on the British pattern were introduced in stages. The last stage was reached on April 27, 1961, when Sierra Leone became an independent state within the Commonwealth.

The first years of independence were prosperous. Mineral resources (iron ore and diamonds) brought in substantial revenue, much of which was used for development, particularly education. Njala University College was founded in the early 1960s and amalgamated in 1967 with Fourah Bay College as the University of Sierra Leone.

Sir Milton Margai died in 1964 and was succeeded by his brother, Sir Albert Margai. The opposition All-Peoples' Congress (APC), led by Siaka Stevens, won the 1967 general election. But the army intervened and set up a military government under Lieutenant Colonel Andrew Juxon-Smith. After a year a military revolt restored parliamentary rule under Stevens and the APC.

The subsequent years were stormy, the government regularly imposing states of emergency and executing its political opponents. In 1971 Sierra Leone became a republic with Stevens as executive president. Meanwhile, the economy deteriorated; the supply of iron ore was exhausted and most of the diamonds were smuggled, thus depriving the government of revenue. Stevens' answer to growing dissatisfaction was to introduce one-party rule in 1978.

In 1985 Stevens retired, having chosen the head of the army, Joseph Saidu Momoh, as his successor. Widespread corruption continued, and the economy further deteriorated. The difficulties in the country were compounded by an incipient conflict. The Revolutionary United Front (RUF), led by Corporal Foday Sankoh, asked for inclusion

in the country's government. This was to be the beginning of a long, brutal, and destructive civil war. After a series of coups, Ahmad Tejan Kabbah, the Sierra Leone People's Party candidate, won election, but the RUF did not recognize the new government and the civil war escalated. In May 1997 the Armed Forces Revolutionary Council (AFRC) led by Major Johnny Paul Koroma seized power, sending Kabbah into exile. An escalation of the conflict led to international intervention that enabled President Kabbah to return to Sierra Leone in March 1998. In July 1999 a peace accord was signed that required the RUF and the AFRC forces to disarm in return for a general amnesty. Sankoh and the RUF were included in the government, and it was charged that they were diverting revenue from diamond mining to fund continued fighting. Diplomatic and military intervention from West African groups, the UN, and Britain helped resolve the decade-long conflict that had left the country in shambles; Kabbah was once again elected president in May 2002.

For later developments in the history of Sierra Leone, see the BRITANNICA BOOK OF THE YEAR.   (C.Fy./Ed.)

Togo

The Republic of Togo (République Togolaise), a sovereign western African nation, consists of that part of the former German colony of Togoland that was made French-mandated territory after World War I. Situated on the Gulf of Guinea, it has a total area of 21,925 square miles (56,785 square kilometres). From its 32-mile (51-kilometre) coastline, Togo extends northward for about 320 miles between Ghana to the west and Benin to the east to its boundary with Burkina Faso in the north. Lomé, the capital, is the largest city and port.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief, drainage, and soils.* Togo consists of six geographic regions. The low-lying, sandy beaches of the narrow coastal region are backed by tidal flats and shallow lagoons, the largest of which is Lake Togo. Beyond the coast lies the Ouatchi Plateau, which stretches about 20 miles inland at an altitude of some 200 to 300 feet (60 to 90 metres). This is the region of the so-called *terre de barre,* a lateritic (reddish, leached, iron-bearing) soil.

Northeast of the plateau is a tableland, the highest altitudes reaching 1,300 to 1,500 feet. This region is drained by the Mono River and its tributaries, including the Ogou, and other smaller rivers. West and southwest of the tableland the terrain gradually rises toward the Togo Mountains, which run across central Togo from the south-southwest to the north-northeast. Part of a chain that begins in the Atakora Mountains of Benin, the range ends in the Akwapim Hills of Ghana. Mount Baumann (Agou), which rises to about 3,235 feet (986 metres), is the highest mountain in Togo. Beyond the Togo Mountains to the north lies the Oti River sandstone plateau. This is a savanna region drained by the Oti River, one of the main tributaries of the Volta. To the far northwest is a higher region of granite and gneiss; the cliffs of Dapaong (Dapango) are located in this region.

Climate. Togo has a tropical climate. In the south the rainy seasons occur from mid-April through June and from mid-September through October. The narrow coastal zone, which receives about 35 inches (890 millimetres) of rain annually, is the driest region. The region of Kpalimé (Palimé), about 65 miles inland, receives the highest amount of rain—about 70 inches annually. The north has only one rainy season with an average rainfall of about 45 inches, mostly falling from June to the end of September; during the rest of the year the warm, dry harmattan (a dust-laden wind) predominates. Mean annual temperatures vary from 79° F (26° C) along the coast and in the mountains to 82° F (28° C) on the northern plateau. Daily minimum temperatures of about 68° F (20° C) are recorded in the mountains in August. Daily maxima of about 100° F (38° C) occur in the north during March and April at the end of the long dry season.

Plant and animal life. Savanna-type vegetation is predominant in Togo. On the southern plateaus large trees,

Margin notes: African rule · Civil war · Togo's six geographic regions

including the baobab, are common, but they are rare in the north. The southwestern highland regions are covered with tropical forests, also found along the river valleys. The coastal zone is dotted with mangrove and reed swamps.

Wild animals are not found in great numbers, especially in the southern and central regions. A few lions, leopards, and elephants can be seen in the north. Monkeys, snakes, and lizards are numerous in many areas, and crocodiles and hippopotamuses abound in the rivers. In the Keran Forest Reserve near Sansanné-Mango in the north, there are wild herds of buffalo, asses, warthogs, antelope, and deer. Numerous species of birds and insects are found in the country. Fish caught off the coast include mackerel, bass, seabream, red snapper, triggerfish, dorado, ray, and sole, while crustaceans include shrimp and lobster.

Settlement patterns. The majority of Togo's population live in small villages scattered throughout the rural areas. A common sight along the coast is the rectangular houses built either of clay and timber or of coconut or palm branches and topped by double-eaved thatched roofs. Scattered throughout the coconut plantations, they are not far from the beaches. Inland in the south, thatched rectangular huts made of adobe are clustered around big trees and surrounded by earthen walls or fences made of palm branches. In the north, the traditional adobe or stone huts are circular and are topped by conical roofs or thatched turrets. They are usually gathered in units corresponding to family groups; often enclosed by earthen walls, they are sometimes interlinked. Distinctive of the northern Kara region is the high density of villages that stretch along the highway or climb up the slopes of the many hills.

Lomé, the largest urban centre, is spread along the coast. At its centre, there is a mixture of old and new commercial and administrative buildings. The traditional housing unit is the big, walled compound composed of a group of isolated rooms, each opening onto a courtyard.

Aného (Anécho), another coastal town, was once the country's leading European trade centre but is now declining. Other main towns include Tsévié and Tabligbo in the lowland plateau; Kpalimé, Atakpamé, Sokodé, Bassar (Bassari), and Kara (Lama-Kara) at the base of the Togo Mountains; and Sansanné-Mango (Mango) and Dapaong in the far north.

The **people.** The population of Togo comprises about 30 ethnic groups, many of whom are immigrants from other parts of western Africa. The groups indigenous to Togo live in the north and southwest. The northern groups include the following Gur-speaking Voltaic peoples: the Gurma; the Natemba, Dye, Bu-Bankam, Bu-Kombong, and Konkomba; the Tamberma; the Basari; the Moba; the Naudemba (Losso); the Kabre and Logba; and the Namba (Lamba); a small number of West Atlantic-speaking Fulani; and the Kebu (Akebu). In the southwest the indigenous Kwa peoples also belonging to the central Togo group are the Akposo, the Adele, and the Ahlo.

The immigrants came from east, west, and north. The Ewe, who emigrated from Nigeria between the 14th and 16th century, form the major ethnic group. There are also some scattered Yoruba, mainly Ana. Groups who emigrated from present-day Ghana and Côte d'Ivoire since the 17th century include the Ane (or Mina), the Ga-Adangme, the Kpelle and the Anyana, the Chakossi, and the Dagomba. The northern groups of the Tem (Kotokoli and Temba), Gurma, and Mossi came from the north, mainly from areas in Burkina Faso.

Most of the nation's non-Africans live in Lomé. Mainly French, they include a few mulattoes of Brazilian, German, and French ancestry. Brazilians, or Portuguese of Brazilian birth, constituted the original trading settlement in Togo, and today Brazilian mulattoes are closely associated with economic and political development.

Although Christianity has profoundly marked the country, more than half the population still adhere to traditional animistic beliefs and in the south participate in *voudou* (voodoo) cults. The main Protestant (Calvinistic) church has been governed for a long time by Togolese moderators. Since independence, the Roman Catholic church in Togo has been headed by a Togolese archbishop. There is also a growing Islāmic population.

Side note: Rural settlement

Side note: The Ewe immigrants

The economy. To encourage private investment, the Investment Code of 1965 guaranteed foreign investors the right of freely transferring abroad all investment capital and income. The code also provided for tax benefits for priority enterprises. The trend in the 1970s of direct state involvement in the economy changed in the early 1980s to a pattern of offering incentives for foreign investment and privatization of state enterprises.

Indirect taxes, almost entirely on imports and exports, account for most of the government's ordinary budget revenues. Direct taxes consist of an income tax, a progressive tax on all profits, taxes on wages paid by employers, a tax on rental values and land, and head taxes.

Unlike other former French territories, Togo has not extended preferential trade treatment to France and subsequently to the European Economic Community. This open-door, nondiscriminatory trade policy—together with the expanded production of phosphate and tropical produce—has contributed to the development of the economy.

Resources. Phosphate is the major mineral resource and by far the country's leading export item. The deposits at Hahoetoé and Kpogamé, directly northeast of Lomé, are mined by the government's Togolese Office of Phosphates. Togo is one of the world's largest phosphate producers. Marble is quarried by Sotoma (Société Togolaise de Marbres et de Matériaux), a mixed-economy company with shares held by the Togolese government and an Italian firm. Togo's considerable limestone reserves, also mined near Lomé, are utilized primarily for cement production.

Other mineral resources with commercial potential include iron ore, bauxite, uranium, chromite (an oxide of iron and chromium), gold, diamonds, rutile (titanium dioxide), manganese oxide, and kaolin (china clay). While the iron ore reserves are large, the metal content is only slightly more than 50 percent. The bauxite has a low mineral content.

Agriculture, forestry, and fishing. The variety of soils and climates enables Togo to grow a wide range of products. Export crops include cocoa beans, coffee, shea nuts, cotton, and palm kernels; staple crops are corn (maize), cassava, rice, yams, sorghum, millet, and peanuts (groundnuts).

Cattle, sheep, and pigs are raised in the plateau region and the north. Fishing is carried out on the coast and in the well-stocked inland rivers and ponds. Most of the catch is consumed locally. Forests, which cover about one-fourth of Togo's total area, are a source of tropical hardwoods and other products.

A government agency, the Office of Agricultural Products of Togo, has a monopoly on the foreign sale of Togolese products. Export sales are made by local firms in Paris and London, acting as agents of the Office.

Industry. Mining and quarrying dominate industry in Togo. Manufacturing in the past centred on the processing of agricultural commodities and the import substitution of consumer goods (textiles, footwear, beverages, and tires). In the late 1970s and early 1980s, however, major investments in heavy industrial schemes included a cement plant, a petroleum refinery, a steelworks, and a phosphoric acid plant, but some of these have since closed down.

Trade. Imports include machinery, transport equipment, food, construction materials, pharmaceuticals, and paper products. Low customs duties have encouraged significant smuggling of imported consumer goods to neighbouring countries with higher tariffs, especially Ghana. Besides phosphate and agricultural products, some refined petroleum and cement are exported. Togo's main trading partners are France, The Netherlands, and Germany.

Transportation. The three main road systems are the scenic coastal road between Ghana and Benin; the road from Lomé north to Burkina Faso; and roads serving the cocoa- and coffee-producing area of Kpalimé, Badou, and Atakpamé.

The government-owned national railway consists of four lines, all of which emanate from Lomé. One line connects Kpalimé with the capital; other lines run to Aného, Tabligbo, and Blitta.

Lomé is Togo's principal port. Its artificial harbour was inaugurated in 1968. A second port at Kpémé, about 22

Side note: The open-door trade policy

miles northeast of Lomé, is used exclusively to handle phosphate shipments.

The international airport at Lomé links Togo with European and other African countries. A second international airport at Niamtougou in the north opened in the early 1980s. There are local airports in Atakpamé, Sokodé, Sansanné-Mango, and Dapaong.

Administration and social conditions. *Government.* The military coup d'état of 1967 abolished the constitution of 1963 and dissolved the National Assembly. Togo had been ruled since 1969 by the Rally of the Togolese People, the sole political party until 1991 when parties were legalized. A new constitution in 1992 established the president as head of state and an elected multiparty National Assembly. The president appoints the prime minister from the parliament majority.

Local govern-ment

The country is divided into five *régions*—Maritime, Plateaux, Centrale, Kara, and Savanes—for the purposes of economic planning. The five *régions* are subdivided into 21 *préfectures,* each of which is headed by a district chief assisted by a district council. Seven *communes* have been established—for the cities of Aného, Atakpamé, Bassar, Lomé, Kpalimé, Sokodé, and Tsévié, respectively.

The administrative apparatus is complemented by traditional authorities, which include tribal kings or chiefs, village chiefs, and heads of family groups. These traditional authorities play a role in the judicial system, dealing with certain questions of customary law. The judicial system, headed by a Supreme Court, consists of a number of law courts in which civil, commercial, administrative, and criminal cases are heard.

Education. Education is modeled after the French system. Togolese teachers, who have replaced French personnel to a large extent, are expected to adapt the system to the Togolese context. Primary and secondary education is provided by public or parochial schools.

The University of Benin at Lomé (founded in 1970) has schools of humanities and science and a university institute of technology. A school of architecture and town planning, also at Lomé, was founded in 1975 by the African and Mauritian Common Organization (OCAM).

Tradi-tional culture

Cultural life. Like other African peoples, the Togolese have a strong oral tradition. Little has been done, however, to promote vernacular literature. Before independence there were a few Togolese writers using French. Since independence, regional (especially Ewe) literature emerged with the works of several novelists and playwrights. Founded in 1967, the African Ballet of Togo has aimed at popularizing the finest traditional dances.

(M.K.P./S.De.)

For statistical data on the land and people of Togo, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

Until 1884 Togoland was an indeterminate buffer zone between the warring states of Asante and Dahomey. The only port was Petit Popo (Anécho, or Aného). Throughout the 18th century the Togo part of the Slave Coast was held by the Danes.

German occupation. German missionaries arrived in Ewe territory in 1847, and German traders were soon established at Anécho. In 1884 Gustav Nachtigal, sent by the German government, induced a number of coastal chiefs to accept German protection. The protectorate was recognized in 1885, and its coastal frontiers with Dahomey and the Gold Coast were defined by treaties with France and Great Britain. German military expeditions (1888–97) met with little resistance, securing a hinterland the boundaries of which also were determined by treaties with France (1897) and Great Britain (1899).

Lomé, at the western end of the coast, was selected as the colonial capital in 1897, a modern town was laid out, and in 1904 a jetty was built. Three railways were constructed to open up the interior. Exploitation was confined to the coastal and central areas and was exclusively agricultural. Plantations were established both by the government and by private German corporations, but crop development was left mainly to the Togolese, assisted by agriculturists

trained at a college in Nuatja (Notsé). Upwardly mobile Ewe were recruited into what was supposed to be Germany's *Musterkolonie* (model colony). Trade was chiefly in palm products, rubber, cotton, and cocoa. German administration was efficient but marred by its harsh treatment of Africans and use of forced labour.

On Aug. 7, 1914, at the outset of World War 1, British and French colonial troops from the Gold Coast and Dahomey invaded Togoland and on August 26 secured the unconditional surrender of the Germans. Thereafter the western part of the colony was administered by Britain, the eastern part by France. By an Anglo-French agreement of July 10, 1919, France secured the railway system and the whole coastline. After Germany renounced its sovereignty in the Treaty of Versailles, the League of Nations in 1922 issued mandates to Britain and France for the administration of their spheres.

League of Nations mandate. The northern part of the British-mandated territory was administered with the Northern Territories of the Gold Coast, the southern part with the Gold Coast Colony. Although the British administration built roads connecting its sphere with the road system of the Gold Coast, the bulk of the territory's external trade passed over the railways of French Togo.

British and French administra-tion

French Togo was administered by a commissioner assisted by a consultative executive council. When British Togo was attached to the Gold Coast, French Togo was formed into a distinct unit until 1934, when a kind of economic union was established with Dahomey; this was replaced in 1936 by a qualified integration with French West Africa that lasted 10 years. Agricultural development was pursued, and a planned settlement of the interior by the Kabre and other peoples was carried out. Peanut growing was introduced in the northern areas, and energetic action was taken against sleeping sickness.

After World War II French Togo sent a deputy to the French National Assembly, a counselor to the Assembly of the French Union, and two senators to the Council of the Republic. A representative assembly was concerned with internal affairs.

United Nations trusteeship. In 1946 the British and French governments placed their spheres of Togoland under UN trusteeship. After 1947 the Ewe people in southern Togoland represented to the Trusteeship Council that either their territories or the whole of Togoland should be brought under a common administration. These proposals were difficult to implement because Ewe also inhabited the southeastern part of the Gold Coast Colony and because not all the people of southern Togoland were Ewe. The British colony was also rapidly advancing toward self-government, and the incorporation of the northern part of the British sphere with the Northern Territories of the Gold Coast had reunited the Dagomba and Mamprusi kingdoms, both of which had been cut in two by the pre-1914 boundary. Following a plebiscite held under UN auspices on May 9, 1956, the British trust territory of Togoland was on December 13 incorporated into the Gold Coast (although in the southern districts of Ho and Kpandu the Ewe vote showed a two-to-one majority in favour of continued British trusteeship). The Gold Coast and Togoland together were renamed Ghana and achieved independence in 1957.

Independence. French Togoland became an autonomous republic within the French Union on Aug. 30, 1956. This status was confirmed (despite Ewe opposition) by a plebiscite held in October under French auspices. Nicolas Grunitzky was appointed premier. Following UN representations, elections in April 1958 favoured complete independence and rejected Grunitzky's Togolese Progress Party in favour of Sylvanus Olympio's Togolese National Unity Party. Togo became independent on April 27, 1960.

After the 1961 elections, which established a presidential form of government, Olympio became the first president. He maintained economic cooperation with France. Togo became a member of the Organization of African Unity (OAU) in 1963 and in 1965 subscribed to the renewed Joint African and Malagasy Organization, which provided for economic, political, and social cooperation among French-speaking African states.   (H.J.D./S.De.)

Ghanaian pressure for the integration of Togo with Ghana was resisted by the Togolese and led to strained relations between the two republics. Olympio's increasingly harsh rule and fiscal austerity ended on Jan. 13, 1963. Having rejected petitions to integrate into the national army Togolese noncommissioned officers recently demobilized from France's colonial armies, Olympio was shot at the gates of the U.S. Embassy (while seeking sanctuary) by Sergeant Étienne Gnassingbé Eyadéma (later called Gnassingbé Eyadéma). Grunitzky was invited to return from exile and assume the presidency, and he was confirmed in office in subsequent elections that also created a new constitution and legislature. Most of the noncommissioned officers were integrated into an expanded army—many as officers.

Cabinet infighting led to chronic instability. In the south the Ewe felt that with Olympio's assassination they had lost power to Grunitzky's largely pro-northern administration. On Jan. 13, 1967, Eyadéma, then a lieutenant colonel, seized power and dissolved all political parties. Though relying primarily on the support of his northern kinsmen and the largely northern-staffed army, Eyadéma's rule was stabilized by a number of other factors. Phosphate exports dramatically improved the economic picture, allowing the regime to satisfy regional and ethnic interests and to begin the first serious effort at transforming the countryside. Meticulous ethnic balancing of the cabinet and an open-door economic policy further attracted support, and in 1972 Eyadéma sought popular legitimation via a presidential plebiscite.

In 1974 the phosphate industry was nationalized, generating increased state revenues. In December 1979 the first legislative elections since 1967 were held under a new constitution that formally put Togo under civilian, one-party rule headed by President Eyadéma and the Rally of the Togolese People. In 1985 legislative elections were held again, followed by Eyadéma's reelection the next year. In 1992 a new democratic constitution was enacted affirming the legality of political parties. Ostensibly free and fair presidential elections were held in 1993, 1998, and 2003 that returned Eyadéma to power, but each brought accusations of fraud. Most of Eyadéma's opponents were Ewe from the south (including the self-exiled sons of Olympio) rebelling against the northerner Eyadéma and his cult of personality. Bombings, strikes, and sometimes-violent demonstrations plagued Eyadéma as well. The regime's patronage base was also undermined in the 1980s and '90s by falling global prices for phosphates, which led to sharply lower state revenues, while growing corruption and massive expenditures on the bloated civil service and inefficient public enterprises strained the state's fiscal resources. Togo's costly government-owned industries were dismantled or privatized, and the country's heavy national debt was often rescheduled.

After Eyadéma's unexpected death in February 2005, his son, Faure Gnassingbé, became president, first through controversial installation by the military, then in an election that drew widespread protest from the opposition. Dozens of people were killed and hundreds were wounded throughout the campaign, and thousands fled the country in the violent aftermath. (S.De./Ed.)

For later developments in the history of Togo, see the BRITANNICA BOOK OF THE YEAR.

BIBLIOGRAPHY

Physical and human geography: Profiles of the western African countries are found in *Africa Contemporary Record* (annual); *West Africa Annual;* and DONALD GEORGE MORRISON, ROBERT CAMERON MITCHELL, and JOHN N. PADEN, *Black Africa: A Comparative Handbook,* 2nd ed. (1989). The physical environment is explored in REUBEN K. UDO, *A Comprehensive Geography of West Africa* (1978), and *The Human Geography of Tropical Africa* (1982); J.B. WRIGHT (ed.), *Geology and Mineral Resources of West Africa* (1985); BRIAN HOPKINS, *Forest and Savanna,* 2nd ed. (1974), on West African tropical ecology; and F. WHITE, *Vegetation of Africa* (1983). RICHARD W. FRANKE and BARBARA H. CHASIN, *Seeds of Famine* (1980), is a study of the 1969–74 Sahelian famine. KATHLEEN M. BAKER, *Indigenous Land Management in West Africa: An Environmental Balancing Act* (2000), studies tropical resource management. JOHN C. CALDWELL (ed.), *Population Growth and Socio-economic Change in West Africa* (1975), surveys demographic conditions by region.

Migration and urbanization are examined in SAMIR AMIN (ed.), *Modern Migrations in Western Africa* (1974); JOSEF GUGLER and WILLIAM G. FLANAGAN, *Urbanization and Social Change in West Africa* (1978); and K.C. ZACHARIAH and JULIEN CONDÉ, *Migration in West Africa* (1981).

Economic history and development are analyzed by A.G. HOPKINS, *An Economic History of West Africa* (1973); and DOUGLAS RIMMER, *The Economies of West Africa* (1984). MARTIN LYNN, *Commerce and Economic Change in West Africa: The Palm Oil Trade in the Nineteenth Century,* new ed. (2002), examines post-slavery trade in the region. Also useful is J.O.C. ONYEMELUKWE and M.O. FILANI, *Economic Geography of West Africa* (1983). Works on agriculture include ROBERT H. BATES, *Markets and States in Tropical Africa* (1981); KEITH HART, *The Political Economy of West African Agriculture* (1982); JONATHAN BARKER (ed.), *The Politics of Agriculture in Tropical Africa* (1984); and PAUL RICHARDS, *Indigenous Agricultural Revolution* (1985).

Traditional cultures: Overviews of African culture are provided by GEORGE MURDOCK, *Africa: Its Peoples and Their Culture History* (1959), still recommended; and JOCELYN MURRAY (ed.), *Cultural Atlas of Africa* (1981). Survey articles on the major ethnic groups may be found in GEORGES BALANDIER and JACQUES MAQUET (eds.), *Dictionary of Black African Civilization* (1974; originally published in French, 1968).

(Western Sudan cultures): A summary of Wolof and Serer ethnography is DAVID P. GAMBLE, *The Wolof of Senegambia, Together with Notes on the Lebu and the Serer* (1957, reprinted 1967). PAUL PÉLISSIER, *Les Paysans du Sénégal* (1966), describes Wolof, Serer, Malinke, and Diola agriculture. On the Mossi, see PETER B. HAMMOND, *Yatenga: Technology in the Culture of a West African Kingdom* (1966); and SUZANNE LALLEMAND, *Une Famille mossi* (1977). Sources for the Fulani include DERRICK J. STENNING, *Savannah Nomads* (1959); and MARGUERITE DUPIRE, *Peuls nomades: étude descriptive des Wodaabe du Sahel nigérien* (1962). Two studies of ethnic culture in urban areas are ENID SCHILDKROUT, *People of the Zongo* (1978); and JOHN N. PADEN, *Religion and Political Culture in Kano* (1973), on the Hausa and Fulani in Kano, Nigeria. PATRICK R. MCNAUGHTON, *The Mande Blacksmiths* (1988), describes artistic, social, and spiritual realms of Mande smiths. Other works include BARBARA J. CALLAWAY, *Muslim Hausa Women in Nigeria* (1987); and CHARLES PIOT, *Remotely Global: Village Modernity in West Africa* (1999), about the Kabre in northern Togo.

(Guinea Coast cultures): Ethnographic studies include WILLIAM TORDOFF, *Ashanti Under the Prempehs, 1888–1935* (1965); IVOR WILKS, *Asante in the Nineteenth Century* (1975); DENNIS M. WARREN, *The Akan of Ghana,* rev. ed. (1986); LEO SPITZER, *The Creoles of Sierra Leone: Responses to Colonialism, 1870–1945* (1974); J.S. EADES, *The Yoruba Today* (1980); ROSEMARY L. HARRIS, *The Political Organization of the Mbembe, Nigeria* (1965); MICHAEL JACKSON, *The Kuranko* (1977); J.D.Y. PEEL, *Ijeshas and Nigerians: The Incorporation of a Yoruba Kingdom, 1890s–1970s* (1983); MICHEL VERDON, *The Abutia Ewe of West Africa* (1983); DARYLL FORDE, *Yako Studies* (1964); and VICTOR C. UCHENDU, *The Igbo of Southeast Nigeria* (1965).

(M.B.T./D.P.Ga./R.L.Ha.)

History: Much original work is available only in articles in such journals as *Journal of African History* (3/yr.); *The International Journal of African Historical Studies* (quarterly); *History in Africa* (annual); *African Affairs* (quarterly); and *The Journal of Modern African Studies* (quarterly). The standard work is J.F. ADE AJAYI and MICHAEL CROWDER (eds.), *History of West Africa,* 2nd ed., 2 vol. (1976–87). In addition there are the western African chapters with comprehensive bibliographies and bibliographical essays in J.D. FAGE and ROLAND OLIVER (eds.), *The Cambridge History of Africa,* 8 vol. (1975–86); and there are some stimulating contributions in UNESCO INTERNATIONAL SCIENTIFIC COMMITTEE FOR THE DRAFTING OF A GENERAL HISTORY OF AFRICA, *General History of Africa* (1981–93), but its bibliographies are less reliable. Useful atlases include J.D. FAGE, *An Atlas of African History,* 2nd ed. (1978); and J.F. ADE AJAYI and MICHAEL CROWDER (eds.), *Historical Atlas of Africa* (1985). A short handbook is J.D. FAGE, *A History of West Africa,* 4th ed. (1969). EUGENE L. MENDONSA, *West Africa: An Introduction to Its History, Civilization and Contemporary Situation* (2002), is an overview.

For French-speaking territories, JEAN SURET-CANALE, *French Colonialism in Tropical Africa, 1900–1945* (1971; originally published in French, 1964), contains useful material; and JOHN D. HARGREAVES, *West Africa, the Former French States* (1967), is an excellent short study. RONALD H. CHILCOTE, *Portuguese Africa* (1967), is a useful general work. RAYMOND MAUNY, *Tableau géographique de l'Ouest africain au Moyen Âge* (1961), contains much useful information up to about AD 1400, though it should be supplemented by later research, such as NEHEMIAH LEVTZION, *Ancient Ghana and Mali* (1973, reprinted 1980). Other useful works for the pre-jihad history of the western and central Sudan are the classic works by E.W. BOVILL, *The Golden*

Trade of the Moors, 2nd ed. rev. by ROBIN HALLETT (1968); and CHARLES MONTEIL, *Les Empires du Mali* (1930, reissued 1968).

Three works on the early history of Guinea may be recommended: J.D. FAGE, "Upper and Lower Guinea," ch. 6 in *The Cambridge History of Africa*, vol. 3, pp. 463–518 (1977); FRANK WILLETT, *Ife in the History of West African Sculpture* (1967); and ROBERT SMITH, *Kingdoms of the Yoruba*, 3rd ed. (1988). The coming of the European traders to the Guinea Coast is treated in JOHN W. BLAKE, *West Africa: Quest for God and Gold, 1454–1578*, 2nd ed. rev. and enlarged (1977). PHILIP D. CURTIN, *The Atlantic Slave Trade* (1969), provided an innovative analysis; but the basic data have been reworked in a useful general history, PAUL E. LOVEJOY, *Transformations in Slavery* (1983).

The subsequent history of Guinea has occasioned many important monographs, such as JOHN VOGT, *Portuguese Rule on the Gold Coast, 1469–1682* (1979); WALTER RODNEY, *A History of the Upper Guinea Coast, 1545–1800* (1970, reprinted 1982); A.F.C. RYDER, *Benin and the Europeans, 1485–1897* (1969); RAY A. KEA, *Settlements, Trade, and Polities in the Seventeenth-Century Gold Coast* (1982); PHILIP D. CURTIN, *Economic Change in Precolonial Africa* (1975); DAVID NORTHRUP, *Trade Without Rulers: Pre-colonial Economic Development in Southeastern Nigeria* (1978); and ROBIN LAW, *The Oyo Empire, c. 1600–c. 1836* (1977). PETER B. CLARKE, *West Africa and Islam* (1982), is a useful introductory work, covering the 8th to the 20th century. For the great outburst of Islām in western Africa in the 18th and 19th centuries, see MURRAY LAST, *The Sokoto Caliphate* (1967, reprinted 1977); and DAVID ROBINSON, *The Holy War of Umar Tal: The Western Sudan in the Mid-nineteenth Century* (1985).

The growth of European influence is covered in works such as ROBIN HALLETT, *The Penetration of Africa: European Exploration in North and West Africa to 1815* (1965); A. ADU BOAHEN, *Britain, the Sahara, and the Western Sudan, 1788–1861* (1964); PHILIP D. CURTIN, *The Image of Africa: British Ideas and Action, 1780–1850* (1964, reissued 1973); K. ONWUKA DIKE, *Trade and Politics in the Niger Delta, 1830–1885* (1956, reprinted 1981); BERNARD SCHNAPPER, *La Politique et le commerce français dans le Golfe de Gunée, de 1838 à 1871* (1961); and J.F. ADE AJAYI, *Christian Missions in Nigeria, 1841–1891* (1965). For the European partition of western Africa, the standard works are JOHN D. HARGREAVES, *Prelude to the Partition of West Africa* (1963), and *West Africa Partitioned*, 2 vol. (1974–85); but see also HENRI BRUNSCHWIG, *French Colonialism, 1871–1914* (1966; originally published in French, 1960); and A.S. KANYA-FORSTNER, *The Conquest of the Western Sudan* (1969).

For the colonial period, two contemporary studies are invaluable: LORD HAILEY (WILLIAM MALCOLM HAILEY), *An African Survey*, rev. ed. (1957, reprinted 1968); and S. HERBERT FRANKEL, *Capital Investment in Africa* (1938, reprinted 1969). For indirect rule, MARGERY PERHAM, *Native Administration in Nigeria* (1937, reprinted 1962), is a classic. A general synthesis is provided by MICHAEL CROWDER, *West Africa Under Colonial Rule* (1968); see also MICHAEL CROWDER and OBARO IKIME (eds.), *West African Chiefs: Their Changing Status Under Colonial Rule* (1970); and MICHAEL CROWDER (ed.), *West African Resistance: The Military Response to Colonial Occupation*, new ed. (1978). The chapters on western Africa in L.H. GANN and PETER DUIGNAN (eds.), *Colonialism in Africa, 1870–1960*, vol. 1–2 (1969–70), are often extremely valuable. There is much useful material in two collections: PROSSER GIFFORD and WM. ROGER LOUIS (eds.), *Britain and Germany in Africa* (1967), and *France and Britain in Africa* (1971).

Works dealing with the transition to independence include JOHN D. HARGREAVES, *The End of Colonial Rule in West Africa* (1979), and *Decolonization in Africa* (1988); KEN POST, *The New States of West Africa*, rev. ed. (1968); RUTH SCHACHTER MORGENTHAU, *Political Parties in French-speaking West Africa* (1964); PROSSER GIFFORD and WM. ROGER LOUIS (eds.), *The Transfer of Power in Africa: Decolonization, 1940–1960* (1982); and EDWARD MORTIMER, *France and the Africans, 1944–1960* (1969).

General works on the period since independence include overviews in vol. 8 of *The Cambridge History of Africa* (1986). Treatments of politics include JOHN DUNN (ed.), *West African States: Failure and Promise* (1978); and PATRICK CHABAL (ed.), *Political Domination in Africa* (1986). For the Francophone states, a good recent survey is PATRICK MANNING, *Francophone Sub-Saharan Africa, 1880–1985* (1988). No comparable survey exists for the Anglophone states, but see PETER DUIGNAN and ROBERT H. JACKSON (eds.), *Politics and Government in African States, 1960–1985* (1986). An introduction to the Lusophone states is BASIL DAVIDSON, *No Fist Is Big Enough to Hide the Sky* (1981), on Guinea and Cape Verde. For recent events, the weekly *West Africa* is indispensable.   (J.D.F./T.C.McC.)

Western Sudan nations. *Burkina Faso:* General works include YVES PÉRON and VICTOIRE ZALACAIN (eds.), *Atlas de la Haute-Volta* (1975); GINETTE PALLIER, *Géographie générale de*

la Haute-Volta (1978); NORBERT NIKIÉMA, *La Situation linguistique en Haute-Volta* (1980); and CLAUDETTE SAVONNET-GUYOT, *Etat et sociétés au Burkina* (1986). No general history exists, but DANIEL MILES MCFARLAND, *Historical Dictionary of Upper Volta (Haute Volta)* (1978), provides useful information. Precolonial and conquest history and ethnography are treated in JEAN CAPRON, *Communautés villageoises bwa: Mali, Haute-Volta* (1973); MICHEL IZARD, *Introduction à l'histoire des royaumes mossi*, 2 vol. (1970); PAUL IRWIN, *Liptako Speaks* (1981); and ANNE-MARIE DUPERRAY, *Les Gourounsi de Haute-Volta: conquéte et colonisation, 1896–1933* (1984). The colonial and independence periods are covered by JEAN AUDOUIN and RAYMOND DENIEL, *L'Islam en Haute-Volta à l'époque coloniale* (1978); SALFO ALBERT BALIMA, *Genése de la Haute-Volta* (1970); SIDIKI COULIBALY, JOEL GREGORY, and VICTOR PICHÉ, *Les Migrations voltaïques*, vol. 1 (1980); and ELLIOT P. SKINNER, *The Mossi of the Upper Volta* (1964). FRANÇOIS D. BASSOLET, *Évolution de la Haute-Volta, de 1898 au 3 janvier 1966* (1968), is a subjective account of the postindependence era.   (M.Ec.)

Cape Verde: ANTÓNIO COSTA, *Cabo Verde*, 2 vol. (1980–81), is an overview of the islands' geography and natural history. COLM FOY, *Cape Verde* (1988), provides information on the postindependence nation. DEIRDRE MEINTEL, *Race, Culture, and Portuguese Colonialism in Cabo Verde* (1984), analyzes social structures and the role of race. ANTÓNIO CARREIRA, *The People of the Cape Verde Islands*, trans. from Portuguese (1982), is a history of emigration. MANUEL FERREIRA, *A aventura crioula*, 3rd ed. rev. (1985), studies cultural life and has an extensive bibliography. CHARLES VERLINDEN, *António de Noli e a colonização das ilhas de Cabo Verde* (1963), discusses the period of discovery and settlement; and T. BENTLEY DUNCAN, *Atlantic Islands* (1972), includes a general history of 17th-century commerce. RICHARD LOBBAN and MARILYN HALTER, *Historical Dictionary of the Republic of Cape Verde*, 2nd ed. (1988), is a useful reference. JOSEPH M. MCCARTHY, *Guinea-Bissau and Cape Verde Islands* (1977), provides a comprehensive bibliography.   (C.S.Sh.)

Chad: HAROLD D. NELSON et al., *Area Handbook for Chad* (1972), is still a useful introduction. See also PIERRE HUGOT, *Le Tchad* (1965); MARIO AZEVEDO (ed.), *Cameroon and Chad in Historical and Contemporary Perspectives* (1989); and JEAN CABOT and CHRISTIAN BOUQUET, *Atlas pratique du Tchad* (1972). Ethnographic studies include JEAN CHAPELLE, *Nomades noirs du Sahara* (1958, reissued 1982), the authoritative study on the Teda; ALBERT LE ROUVREUR, *Sahéliens et sahariens du Tchad* (1962), information about the northern and eastern populations; and JEAN CHAPELLE, *Le Peuple tchadien* (1980). Politics and government are treated in GEORGES DIGUIMBAYE and ROBERT LANGUE, *L'Essor du Tchad* (1969); and MICHAEL P. KELLEY, *A State in Disarray: Conditions of Chad's Survival* (1986), discussing dependency. SAMUEL DECALO, *Historical Dictionary of Chad*, 2nd ed. (1987), has an extensive bibliography. Early history is discussed in JEAN PAUL LEBEUF, *Archéologie tchadienne: les Sao du Cameroun et du Tchad* (1962); and JEAN PAUL LEBEUF and A. MASSON DETOURBET, *La Civilisation du Tchad* (1950). JACQUES LE CORNEC, *Histoire politique du Tchad, de 1900 à 1962* (1963), provides information on the colonial era and the first years of independence. ROBERT BUIJTENHUIJS, *Le Frolinat et les révoltes populaires du Tchad, 1965–76* (1978), and *Le Frolinat et les guerres civiles du Tchad (1977–1984)* (1987), are the best sources of information on Chad's civil wars. The boundary disputes are discussed in BERNARD LANNE, *Tchad-Libye*, 2nd ed. (1986).   (A.T.G.)

The Gambia: OYEYEMI HAFFNER, *A New Geography of Senegambia* (1981); and HUBERT DESCHAMPS, *Le Sénégal et la Gambie*, 3rd ed. updated (1975), are useful introductions. Historical information may be found in J.M. GRAY, *A History of the Gambia* (1940, reissued 1966); HARRY A. GAILEY, *A History of The Gambia* (1964), and *Historical Dictionary of The Gambia*, 2nd ed. (1987); CHARLOTTE A. QUINN, *Mandingo Kingdoms of the Senegambia* (1972); and S.A. BAKARR, *The Gambia Yesterday, 1447–1979* (1980), a historical chronology. For bibliographic information, see DAVID P. GAMBLE (comp.), *The Gambia* (1988).   (H.A.G.)

Mali: PHILIPPE DECRAENE, *Le Mali* (1980); and MAMADOU TRAORÉ and YVES MONNIER (eds.), *Atlas du Mali* (1980), provide overviews. Ethnographic studies include JEAN GALLAIS, *Hommes du Sahel: espaces-temps et pouvoirs: le delta intérieur du Niger, 1960–1980* (1984); DANIELLE JONCKERS, *La Société minyanka du Mali* (1987); and BOKAR N'DIAYÉ, *Groupes ethniques au Mali* (1970). MOUSSA COLA CISSÉ et al., *Le Mali, le paysan et l'état* (1981); and EMIL SCHREYGER, *L'Office du Niger au Mali, 1932 à 1982* (1984), focus on agriculture. GUÉDEL NDIAYE, *L'Échec de la Fédération du Mali* (1980), is a political study. Historical works include PASCAL JAMES IMPERATO, *Historical Dictionary of Mali*, 2nd ed. (1986); ATTILIO GAUDIO, *Le Mali* (1988); AMIDU MAGASA, *Papa-commandant a jeté un grand filet devant nous: les exploités des rives du Niger, 1900–*

1962 (1978), on forced labour and colonization; WILLIAM J. FOLTZ, *From French West Africa to the Mali Federation* (1965), a political history; and CHEICK OUMAR DIARRAH, *Le Mali de Modibo Keïta* (1986). (K.M.B./P.J.I.)

Mauritania: Introductions include ALFRED G. GERTEINY, *Mauritania* (1967); BRIAN DEAN CURRAN and JOANN SCHROCK, *Area Handbook for Mauritania* (1972); CHARLES TOUPET and JEAN-ROBERT PITTE, *La Mauritanie* (1977); and CHARLES TOUPET and GEORGES LACLAVÈRE, *Atlas de la République Islamique de Mauritanie* (1977). CHARLES TOUPET, *La Sédentarisation des nomades en Mauritanie centrale sahélienne* (1977), studies geographic and social transformations. The economy is treated in RICHARD M. WESTEBBE, *The Economy of Mauritania* (1971); and JÉRÔME PUJOS, *Croissance économique et impulsion extérieure: étude sur l'économie mauritanienne* (1964). ALFRED G. GERTEINY, *Historical Dictionary of Mauritania* (1981), is a good reference. Specific periods are examined in C.C. STEWART and E.K. STEWART, *Islam and Social Order in Mauritania: A Case Study from the Nineteenth Century* (1973); FRANCIS DE CHASSEY, *Mauritanie, 1900–1975* (1978, reissued 1984); and GENEVIÈVE M. DÉSIRÉ-VUILLEMIN, *Contribution à l'histoire de la Mauritanie de 1900 à 1934* (1962). (A.G.G.)

Niger: AROUNA HAMIDOU SIDIKOU and PHILIPPE CLAUDE CHAMARD, *Géographie du Niger* (1976); and PIERRE DONAINT and FRANÇOIS LANCRENON, *Le Niger*, 3rd ed. rev. and updated (1984), are general works. Ethnographic studies include CATHERINE BAROIN, *Anarchie et cohésion sociale chez les Toubo* (1985); ANGELO MALIKI BONFIGLIOLI, *Dudal: histoire de famille et histoire de troupeau chez un groupe de Wodaabe du Niger* (1989); PETER FUCHS, *Das Brot der Wüste: Sozio-ökonomie der Sahara-Kanuri von Fachi* (1983); HENRI GUILLAUME, *Les Nomades interrompus: introduction à l'étude du canton twareg de l'Imanan* (1974); JOHANNES NICOLAISEN, *Ecology and Culture of the Pastoral Tuareg* (1963); GUY NICOLAS, *Dynamique sociale et appréhension du monde au sein d'une société hausa* (1975); JEAN-PIERRE OLIVIER DE SARDAN, *Système des relations économiques et sociales chez les Wogo, Niger* (1969); MARC HENRI PIAULT, *Histoire Mawri: introduction à l'étude des processus constitutifs d'un état* (1970); and MAÏKOREMA ZAKARI, *Contribution à l'histoire des populations du sud-est nigérien: le cas du Mangari (XVIe–XIXe s.)* (1985). Two city studies are SUZANNE BERNUS, *Niamey: population et habitat* (1962); and EDMOND BERNUS and SUZANNE BERNUS, *Du Sel et des dattes: introduction à l'étude de la communauté d'In Gall et de Tegidda-n-tesamt* (1972). Historical treatments include EDMOND SÉRÉ DE RIVIÈRES, *Histoire du Niger* (1965); FINN FUGLESTAD, *A History of Niger, 1850–1960* (1983); STEPHEN BAIER, *An Economic History of Central Niger* (1980); and SAMUEL DECALO, *Historical Dictionary of Niger*, 2nd ed. (1987). (F.F.)

Senegal: Overviews are found in HAROLD D. NELSON *et al.*, *Area Handbook for Senegal*, 2nd ed. (1974); HUBERT DESCHAMPS, *Le Sénégal et la Gambie*, 3rd ed. updated (1975); and PHILIPPE DECRAENE, *Le Sénégal* (1985). See also *Atlas national du Sénégal* (1977); and PAUL PÉLISSIER (ed.), *Atlas du Sénégal* (1980). Sociological works include GILLES BLANCHET, *Elites et changements en Afrique et au Sénégal* (1983); and ABDOULAYE-BARA DIOP, *La Famille wolof* (1985). DONAL B. CRUISE O'BRIEN, *The Mourides of Senegal* (1971); CHRISTIAN COULON, *Le Marabout et le Prince: Islam et pouvoir au Sénégal* (1981); and MORIBA MAGASSOUBA, *L'Islam au Sénégal* (1985), discuss the Islamic heritage and present religiopolitical conflicts. Politics and government are studied by MICHAEL CROWDER, *Senegal: A Study of French Assimilation Policy*, rev. ed. (1967); and MAR FALL, *Sénégal, l'état Abdou Diouf* (1986). Historical works include ERIC MAKÉDONSKY, *Le Sénégal: la Sénégambie*, 2 vol. (1987); PHILIP D. CURTIN, *Economic Change in Precolonial Africa* (1975); and SHELDON GELLAR, *Senegal* (1982), on the period since independence. G. WESLEY JOHNSON, JR., *The Emergence of Black Politics in Senegal: The Struggle for Power in the Four Communes, 1900–1920* (1971), is supplemented by KENNETH ROBINSON, "Senegal: The Elections to the Territorial Assembly, March 1957," in W.J.M. MACKENZIE and KENNETH ROBINSON, *Five Elections in Africa* (1960), pp. 281–390. LUCIE GALLISTEL COLVIN, *Historical Dictionary of Senegal* (1981), is a useful reference. (Ca.C./J.D.H.)

Guinea Coast nations. *Benin:* Ethnographic studies include JACQUES LOMBARD, *Structures de type "féodal" en Afrique noire* (1965); WILLIAM J. ARGYLE, *The Fon of Dahomey* (1966); and PAUL MERCIER, *Tradition, changement, histoire: les "Somba" du Dahomey septentrional* (1968). PATRICK MANNING, *Slavery, Colonialism, and Economic Growth in Dahomey, 1640–1960* (1982), is a detailed study. ROBERT CORNEVIN, *La République Populaire du Bénin: des origines dahoméennes à nos jours* (1981), is an indispensable reference. For a treatment of the traditional Dahomey kingdom, see MELVILLE J. HERSKOVITS, *Dahomey: An Ancient West African Kingdom*, 2 vol. (1938, reprinted 1967). DOV RONEN, *Dahomey* (1975), is the only general history of the independent country available in English. I.A.

AKINJOGBIN, *Dahomey and Its Neighbours, 1708–1818* (1967), is the principal published study of the precolonial kingdom of Dahomey. C.W. NEWBURY, *The Western Slave Coast and Its Rulers* (1961, reprinted 1983), is a study of the development of European commerce and imperialism in the 19th century. SAMUEL DECALO, *Historical Dictionary of Benin*, 2nd ed. (1987), has an extensive bibliography. (D.Ro./R.La.)

Cameroon: Descriptions of the physical and cultural environment are given in AARON S. NEBA, *Modern Geography of the Republic of Cameroon*, 2nd ed. (1987); and J.A. NGWA, *A New Geography of Cameroon*, new ed. (1978). MICHAEL G. SCHATZBERG and I. WILLIAM ZARTMAN (eds.), *The Political Economy of Cameroon* (1986), is a collection of essays. MARK W. DELANCEY and H. MBELLA MOKEBA, *Historical Dictionary of the Republic of Cameroon*, 2nd ed. (1990), also contains a chronology and an extensive bibliography. General histories include ENGELBERT MVENG, *Histoire du Cameroun*, 2nd ed., 2 vol. (1984–85), a classic work covering prehistory to independence but concentrating on precolonial and colonial history of French-speaking Cameroon; TAMBI EYONGETAH MBUAGBAW, ROBERT BRAIN, and ROBIN PALMER, *A History of the Cameroon*, 2nd ed. (1987), a brief, readable introduction emphasizing the colonial and postcolonial periods; VICTOR JULIUS NGOH, *Cameroon, 1884–1985* (1987), emphasizing French and British colonial rule and changes since independence; and MARTIN NJEUMA (ed.), *Introduction to the History of Cameroon: Nineteenth and Twentieth Centuries* (1989), seven essays (five by Cameroonians) discussing selected topics including trade and politics just prior to colonial rule, aspects of colonial administration, and the northern *lamidates*. German rule in Cameroon is examined by HARRY R. RUDIN, *Germans in the Cameroons, 1884–1914: A Case Study in Modern Imperialism* (1938, reprinted 1968), the classic study, relying heavily on documents and official reports and presenting a report critical of but generally favourable to the Germans; and HELMUTH STOECKER (ed.), *Kamerun unter deutscher Kolonialherrschaft*, 2 vol. (1960–68), a revisionist view exposing a more exploitative and harsh relationship than in Rudin's work. The best accounts of political history up to the time of reunification are DAVID E. GARDINER, *Cameroon: United Nations Challenge to French Policy* (1963); and VICTOR T. LE VINE, *The Cameroons, from Mandate to Independence* (1964, reprinted 1977), which analyzes the effects of French rule and the rise of independence movements, with some discussion of British rule. RICHARD A. JOSEPH, *Radical Nationalism in Cameroun: Social Origins of the U.P.C. Rebellion* (1977), a history of the most significant preindependence nationalist movement in Cameroon, provides an understanding of the origins of many of the domestic and international political and economic problems of Cameroon. MARK W. DELANCEY, *Cameroon: Dependence and Independence* (1989), provides an analysis of the political, economic and cultural changes incurred in the colonial and independence eras. MARK W. DELANCEY and PETER J. SCHRAEDER (comps.), *Cameroon* (1986), an annotated bibliography of recent publications on history, politics, and economics. (G.Be./M.W.DeL.)

Côte d'Ivoire: T.D. ROBERTS *et al.*, *Area Handbook for Ivory Coast*, 2nd ed. (1973), provides a general overview. RAYMOND BORREMANS, *Le Grand Dictionnaire encyclopédique de la Côte d'Ivoire* (1986–   ), is more current. See also PIERRE VENNETIER (ed.), *Atlas de la Côte d'Ivoire*, 2nd ed. rev. and updated by PIERRE VENNETIER and GENEVIÈVE DAVERAT (1983). Ethnographic studies include ENID SCHILDKROUT (ed.), *The Golden Stool: Studies of the Asante Center and Periphery* (1987); and IVOR WILKS, *Wa and the Wala* (1989). LAURENT GBAGBO, *La Côte-d'Ivoire* (1982), is a history of economic and social developments in the 20 years before independence. For further discussions of economic history and policies, see BASTIAAN A. DEN TUINDER, *Ivory Coast* (1978); GEORGES LORY, *Introduction à l'économie ivoirienne* (1981); I. WILLIAM ZARTMAN and CHRISTOPHER DELGADO, *The Political Economy of Ivory Coast* (1984); and JEAN-PIERRE FOIRRY and DENIS REQUIER-DESJARDINS, *Planification et politique économique en Côte d'Ivoire, 1960–1985* (1986). ARISTIDE R. ZOLBERG, *One-Party Government in the Ivory Coast*, rev. ed. (1969), is a study of political history. Sociological works include ARTHUR CONTE, *Côte d'Ivoire, ou, les racines de la sagesse* (1981); ABDOU TOURÉ, *La Civilisation quotidienne en Côte-d'Ivoire* (1981); and Y.-A. FAURÉ and J.-F. MEDARD (comps.), *État et bourgeoisie en Côte-d'Ivoire* (1982). ROBERT J. MUNDT, *Historical Dictionary of the Ivory Coast (Cote d'Ivoire)* (1987), a valuable reference work, has an extensive bibliography. JEAN-NOËL LOUCOU, *Histoire de la Côte d'Ivoire*, vol. 1, *La Formation des peuples* (1984), presents the origin and development of the country's major ethnic groups. F.J. AMON D'ABY, *La Côte d'Ivoire dans la cité africaine* (1951), is a pioneering and still valuable survey. (J.Co./N.E.L.)

Equatorial Guinea: MAX LINIGER-GOUMAZ, *Small Is Not Always Beautiful* (1988; originally published in French, 1986), *La Guinée Équatoriale* (1979), and *Historical Dictionary of*

Equatorial Guinea, 2nd ed. (1988), are authoritative. RENÉ PÉLISSIER, *Études hispano-guinéennes* (1969), is the only detailed study of the preindependence era. See also SUZANNE CRONJÉ, *Equatorial Guinea, the Forgotten Dictatorship* (1976); AKINJIDE OSUNTOKUN, *Equatorial Guinea–Nigerian Relations* (1978); and ALEJANDRO ARTUCIO, *The Trial of Macías in Equatorial Guinea* (1979). Further bibliographic information is found in MAX LINIGER-GOUMAZ, *Guinea Ecuatorial* (1974), and periodic supplements.   (R.J.H.-C.)

Ghana: E.A. BOATENG, *A Geography of Ghana,* 2nd ed. (1966), is an account of the systematic and regional geography. JACK GOODY, *Changing Social Structure in Ghana* (1975), is an ethnological examination. Political development is studied in DAVID KIMBLE, *A Political History of Ghana: The Rise of Gold Coast Nationalism, 1850–1929* (1963, reprinted 1971); F.M. BOURRET, *Ghana: The Road to Independence, 1919–1957,* rev. ed. (1960); DENNIS AUSTIN, *Politics in Ghana, 1946–1960* (1964); and DAVID E. APTER, *Ghana in Transition,* 2nd rev. ed. (1972). J.D. FAGE, *Ghana* (1959, reprinted 1983); and DANIEL MILES MCFARLAND, *Historical Dictionary of Ghana* (1985), provide introductions. Ghana's historical importance in trading is related by K. YEBOA DAAKU, *Trade and Politics on the Gold Coast, 1600–1720* (1970); J.K. FYNN, *Asante and Its Neighbours, 1700–1807* (1971); and EDWARD REYNOLDS, *Trade and Economic Change on the Gold Coast, 1807–1874* (1974).
(E.A.B./J.D.F.)

Guinea: JEAN SURET-CANALES, *La République de Guinée* (1970), now dated, is the best single source. CLAUDE RIVIÈRE, *Guinea: The Mobilization of a People* (1977), although also dated, is a sound work. HAROLD D. NELSON *et al., Area Handbook for Guinea,* 2nd ed. (1975), is still valuable for background information. 'LADIPO ADAMOLEKUN, *Sékou Touré's Guinea* (1976), is an excellent work on the political system under the country's first president. THOMAS E. O'TOOLE, *Historical Dictionary of Guinea (Republic of Guinea/Conakry),* 2nd ed. (1987), contains an extensive bibliography.   (T.E.O'T.)

Guinea-Bissau: For contemporary settlement and production patterns, ANNE-MARIE HOCHET, *Paysanneries en attente* (1983), is unequaled. Economic and political studies include ROSEMARY E. GALLI, "The Political Economy of Guinea-Bissau," *Africa,* 59(3):371–380 (1989); and CARLOS LOPES, *Guinea-Bissau* (1987). Works on the war for national independence include LUÍS CABRAL, *Crónica da libertação* (1984); LARS RUDEBECK, *Guinea-Bissau: A Study of Political Mobilization* (1974); and STEPHANIE URDANG, *Fighting Two Colonialisms: Women in Guinea-Bissau* (1979). RICHARD LOBBAN and JOSHUA FORREST, *Historical Dictionary of the Republic of Guinea-Bissau,* 2nd ed. (1988), is a useful introduction. A comprehensive historical and contemporary survey through 1986 is ROSEMARY E. GALLI and JOCELYN JONES, *Guinea-Bissau* (1987). A. TEIXEIRA DA MOTA, *Guiné Portuguesa,* 2 vol. (1954), is the standard work on the colonial period, with English and French summaries at the end of both volumes. Other histories include JOÃO BARRETO, *História da Guiné, 1418–1918* (1938); and WALTER RODNEY, *A History of the Upper Guinea Coast, 1545–1800* (1970, reprinted 1982). See also ROSEMARY E. GALLI, *Guinea-Bissau* (1990), an annotated bibliography.   (R.E.Ga./D.Bi.)

Liberia: An overview is found in HAROLD D. NELSON (ed.), *Liberia,* 3rd ed. (1985). Physical features are described in WILLI SCHULZE, *A New Geography of Liberia* (1973). Afro-American 19th-century settlement patterns are analyzed by TOM W. SHICK, *Behold the Promised Land* (1980). Economic and political studies include CHRISTOPHER CLAPHAM, *Liberia and Sierra Leone* (1976); and R.W. CLOWER *et al., Growth Without Development* (1966). D. ELWOOD DUNN and SVEND E. HOLSOE, *Historical Dictionary of Liberia* (1984), provides an introduction. J. GUS LIEBENOW, *Liberia: The Evolution of Privilege* (1969), is supplemented by his *Liberia: The Quest for Democracy* (1987). D. ELWOOD DUNN and S. BYRON TARR, *Liberia* (1988), traces the political development of modern Liberia.   (A.B.J./S.E.H.)

Nigeria: An overview is found in HAROLD D. NELSON (ed.), *Nigeria,* 4th ed. (1982). REUBEN K. UDO, *Geographical Regions of Nigeria* (1970); K.M. BARBOUR *et al., Nigeria in Maps* (1982); and K.M. BUCHANAN and J.C. PUGH, *Land and People in Nigeria* (1955, reissued 1966), are standard geographic texts. AKIN L. MABOGUNJE, *Urbanization in Nigeria* (1968), contains detailed studies of Lagos and Ibadan. W.T.W. MORGAN, *Nigeria* (1983), is a good presentation of the physical and cultural environment. An account of the economy up to World War II can be found in DARYLL FORDE and RICHENDA SCOTT, *The Native Economies of Nigeria* (1964); and GERALD K. HELLEINER, *Peasant Agriculture, Government, and Economic Growth in Nigeria* (1966). SUSAN M. MARTIN, *Palm Oil and Protest: An Economic History of the Ngwa Region, South-eastern Nigeria, 1800–1980* (1988), takes the story up to the oil boom. This last period is best read about in SCOTT R. PEARSON, *Petroleum and the*

Nigerian Economy (1970); and SAYRE P. SCHATZ, *Nigerian Capitalism* (1977); and, in its wider dimension of political economy, in GAVIN WILLIAMS (ed.), *Nigeria* (1976); and I. WILLIAM ZARTMAN (ed.), *The Political Economy of Nigeria* (1983). On politics, JAMES S. COLEMAN, *Nigeria: Background to Nationalism* (1958); and RICHARD L. SKLAR, *Nigerian Political Parties* (1963), remain indispensable; along with K.W.J. POST, *The Nigerian Federal Election of 1959* (1963); JOHN P. MACKINTOSH (ed.), *Nigerian Government and Politics: Prelude to the Revolution* (1966); and LARRY DIAMOND, *Class, Ethnicity, and Democracy in Nigeria: The Failure of the First Republic* (1988). Constitutional development can be followed in B.O. NWABUEZE, *A Constitutional History of Nigeria* (1982). Studies of public administration include BILLY DUDLEY, *An Introduction to Nigerian Government and Politics* (1982); and 'LADIPO ADAMOLEKUN, *Politics and Administration in Nigeria* (1986). EKPO EYO, *Two Thousand Years, Nigerian Art* (1977), traces the development of an important part of Nigeria's culture.

The best general history of Nigeria is MICHAEL CROWDER, *The Story of Nigeria,* 4th ed. rev. (1978); it is supplemented by OBARO IKIME (ed.), *Groundwork of Nigerian History* (1980). Regional and special studies include R.A. ADELEYE, *Power and Diplomacy in Northern Nigeria, 1804–1906: The Sokoto Caliphate and Its Enemies* (1971); E.A. AYANDELE, *The Missionary Impact on Modern Nigeria, 1842–1914* (1966); A.E. AFIGBO, *The Warrant Chiefs: Indirect Rule in Southeastern Nigeria, 1891–1929* (1972); and G.O. OLUSANYA, *The Second World War and Politics in Nigeria, 1939–1953* (1973). The Biafran War is covered in JOHN DE ST. JORRE, *The Nigerian Civil War* (1972). On the Second Republic, RICHARD A. JOSEPH, *Democracy and Prebendal Politics in Nigeria* (1987); TOYIN FALOLA and JULIUS IHONVBERE, *The Rise & Fall of Nigeria's Second Republic, 1979–84* (1985); ANTHONY KIRK-GREENE and DOUGLAS RIMMER, *Nigeria Since 1970* (1981); and WILLIAM D. GRAF, *The Nigerian State* (1988), are informative. See also A. OYEWOLE, *Historical Dictionary of Nigeria* (1987).
(R.K.U./J.F.A.A./A.H.M.K.-G.)

Sierra Leone: D.R.G. GWYNNE-JONES *et al., A New Geography of Sierra Leone* (1978), is an introduction; see also JOHN I. CLARKE (ed.), *Sierra Leone in Maps,* 2nd ed. (1969). KENNETH LITTLE, *The Mende of Sierra Leone,* rev. ed. (1967); MICHAEL JACKSON, *The Kuranko* (1977); W.T. HARRIS and HARRY SAWYERR, *The Springs of Mende Belief and Conduct* (1968); and R.H. FINNEGAN, *Survey of the Limba People of Northern Sierra Leone* (1965), are accounts of the most populous communities. AKINTOLA WYSE, *The Krio of Sierra Leone* (1989), contains an account of the Krio of the western area. On the economy, see RALPH GERALD SAYLOR, *The Economic System of Sierra Leone* (1967). Accounts of modern political developments include GERSHON COLLIER, *Sierra Leone* (1970); WALTER BARROWS, *Grassroots Politics in an African State: Integration and Development in Sierra Leone* (1976); CHRISTOPHER CLAPHAM, *Liberia and Sierra Leone* (1976); THOMAS S. COX, *Civil-Military Relations in Sierra Leone* (1976); ARTHUR ABRAHAM, *Mende Government and Politics Under Colonial Rule* (1978), on the period 1890–1937; JOHN R. CARTWRIGHT, *Political Leadership in Sierra Leone* (1978); and GUSTAV H.K. DEVENEAUX, *Power Politics in Sierra Leone* (1982). CHRISTOPHER FYFE, *A History of Sierra Leone* (1962), is a major historical work; it is complemented by CYRIL P. FORAY, *Historical Dictionary of Sierra Leone* (1977). Other historical studies include C. MAGBAILY FYLE, *The History of Sierra Leone* (1981); ADAM JONES, *From Slave to Palm Kernels: A History of the Galinhas Country (West Africa), 1730–1890* (1983); D.A. TURAY and ARTHUR ABRAHAM, *The Sierra Leone Army: A Century of History* (1987); and MURRAY LAST and PAUL RICHARDS (eds.), *Sierra Leone, 1787–1987: Two Centuries of Intellectual Life* (1987).   (D.S.H.W.N./C.Fy.)

Togo: ROBERT CORNEVIN, *Histoire du Togo,* 3rd ed. rev. and expanded (1969), covers geography, prehistory, ethnology, and history. SAMUEL DECALO, *Historical Dictionary of Togo,* 2nd ed. (1987), is a useful reference with an extensive bibliography. Ethnographic studies include JEAN-CLAUDE FROELICH, PIERRE ALEXANDRE, and ROBERT CORNEVIN, *Les Populations du Nord-Togo* (1963); RAYMOND VERDIER, *Le Pays kabiyé* (1982); and FRANÇOIS DE MEDEIROS (ed.), *Peuples du Golfe du Bénin* (1984). The political evolution of the country since independence is presented in SAMUEL DECALO, "The Benevolent General: Military Rule in Togo," in his *Coups and Army Rule in Africa* (1976), pp. 87–121; and in the issue titled "Togo Authentique," *Politique Africaine,* 27 (September–October 1987). ARTHUR J. KNOLL, *Togo Under Imperial Germany, 1884–1914* (1978), is a study of the German colonial era. COMI M. TOULABOR, *Le Togo sous Eyadéma* (1986); and ANDOCH NUTÉPÉ BONIN, *Le Togo du sergent en général* (1983), discuss the period of military rule.   (S.De.)

Work and Employment

The story of work is a story of humanity's trials and triumphs—from the ordeal of hard work, sometimes under conditions of slavery with obedience mandated by the whip, to the development of tools and machines, which take the burdens off human backs and even human minds. These advances in technology, which will always occur, extend the reach of the hand, expand muscle power, enlarge the senses, and multiply the capacities of the mind. This story of work is still unfolding, with great changes taking place throughout the world and in a more accelerated fashion than ever before.

But work involves more than the use of tools and techniques. The form and nature of the work process help determine the character of a civilization, but, in turn, a society's economic, political, and cultural characteristics shape the form and nature of the work process as well as the role and status of the worker within the society.

Work is essential in providing the basic physical needs of food, clothing, and shelter, and different explanations have been given at different times for its existence and purpose in human survival. Thus, in Chinese civilization, work became part of the Taoist flow of nature to which a person must adapt as part of the natural world. However, in the Judeo-Christian religious tradition (and in pagan religions as well), it was regarded as a punishment sent by God (or by the gods or spirits) to punish human beings for some deviation from the wishes or rules of the divine.

The human spirit, however, is too resilient and optimistic to face an eternal and damning process of hard physical labour, as most work was during most of human history for most people, so more benign explanations of the meaning and purpose of work came into use. For example, in western Christendom the Benedictine monks enunciated the rule that "to work is to pray," to fulfill one's duty to God and thus achieve salvation. This notion of work bringing spiritual rewards, in addition to physical survival, was carried further during the 17th century by the Puritans, who regarded the accumulation of material wealth through labour as a sign of God's favour and of the individual's religious fervour. This attitude still appears in the American expression "You are what you do," implying that people define themselves by the nature of their work.

With the onset of the Industrial Revolution and the development of powered machinery during the 18th and 19th centuries, much onerous physical effort was gradually removed from work in factories and fields. Work was still regarded, however, as something separate from pleasure, and the dichotomy between work and play persists even in today's highly industrialized society.

Most recently, the development of automated work devices and processes and the introduction of the computer into the service trades, especially in offices, has led futurists to speak of a "postindustrial society." This vision has not prevailed, however, with the spread of industrial production to developing nations. This globalization of production has meant that economic and political questions of working-class and managerial relationships have altered on an international front, affecting political relationships on a global scale. Furthermore, new demands have been placed on educational systems in the developing nations as they attempt to train their workers for industrial production. Similarly, new demands have been placed on the educational systems of the developed nations, as the old assembly-line routine of specialized work has been taken over by "smart" machines.

In brief, the world of work, comprising all interactions between workers and employers, organizations, and the work environment, is marked by constant adaptation to changes in the technological, cultural, political, and economic environments. The study of changes in the organization of work resulting from such alterations in the past can perhaps lead to a better understanding of the present problems—now on a worldwide scale—resulting from ongoing technical, political, and economic changes. Hence, this article employs both historical and current perspectives in order to provide a basis for understanding work in today's world and possible changes in the future.

The article begins with a history of the organization of work from the Stone Age to the modern age of computerized automation. The scientific study of the behaviour of workers in organizations of employment is then covered in the following section, on industrial and organizational relations. A section on labour economics presents the economic models that have been used to explain the prices placed upon labour and the products of labour. Finally, the history of organized labour and the structures of labour unions are traced.

A discussion of labour law is included in the article BUSINESS LAW. The design and management of workplaces and work processes are covered in INDUSTRIAL ENGINEERING AND PRODUCTION MANAGEMENT. The principles underlying labour economics are explained in ECONOMIC THEORY. For discussions of the inventions that have shaped the nature of work, see TECHNOLOGY, THE HISTORY OF; and TOOLS. For coverage of the economic activities under which people labour, see FARMING AND AGRICULTURAL TECHNOLOGY and industrial articles such as INDUSTRIES, MANUFACTURING.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia,* sections 533 and 712, and the *Index.*

The article is divided into the following sections:

HISTORY OF THE ORGANIZATION OF WORK

Organization of work in preindustrial times

PREHISTORY

Organization of work may have begun before the evolution of *Homo sapiens*. Along with tools, a more complex brain structure, and linguistic communication, division of labour may have been responsible for starting the human conquest of nature and differentiating human beings from other animal species.

In these early stages of human development, work was confined to simple tasks involving the most basic of human needs: food. There could be no widespread geographic division of labour, because the population was sparse and isolated in small groups. Prehistoric people were largely food gatherers and hunters. The intermittent availability of food allowed little surplus for exchange, and there were few contacts with groups in different places that might have specialized in obtaining different foods. Nevertheless, there was some opportunity to augment the food supply by organizing the work of foraging and hunting and, later, agriculture.

Age, sex, and class. The most obvious division of labour arose from differences in age and sex. The oldest people in the tribe lacked strength and agility to hunt or forage far afield and so performed more sedentary tasks. The very youngest members of the tribe were similarly employed and were taught simple food gathering. There was also a sexual division of labour based upon the fact that women bore and nursed children and could not as easily participate in hunting. Women, however, were required to work as hard as men.

In the earliest human groupings there was no division of labour based upon class. The precarious character of food gathering made it necessary for the whole group to contribute, so that there could be no leisure class or even a class of full-time specialists producing articles not directly related to the food supply. There were, however, part-time specialists. For example, when men learned to make flint tools and weapons, some individuals became so skillful that they could produce a surplus to be exchanged for food.

Communal organization. Although there were no full-time specialists and no true division of labour in prehistory, work nevertheless often required organization. Capture of game and fish required varying degrees of cooperation among members of the group. Communal activity of this type had important social implications. Food had to be equitably shared, and a leader was needed to organize and direct the group. Because the basic social group was the family tribe, kin relationships—from the tribal chief down—formed the basis for the "managerial hierarchy." Bones of large animals killed by hunters have been found in sites of the Upper Paleolithic period (about 40,000 BC to about 10,000 BC), indicating a high degree of organization in hunting at this early stage of human

Early division of labour

development. Shortly thereafter men began using dogs as assistants in hunting.

Pottery. A more complex organization of work came with the development of pottery. While some sort of clay adequate for making passable pottery can be found nearly everywhere, the best potter's clay is not universally distributed. Thus, people in some locations were able to make pottery products for exchange. Skilled workmanship and specialized tools aided production, perhaps further encouraging specialization. There is no conclusive evidence that the earliest potters spent their full time at that task or that pottery making was carried on by women in its primitive stages, before introduction of the potter's wheel. There is reason to believe, however, that in prehistoric times some organization of the work existed. The gathering of the clay and firing materials may have been the work of the men, while the women may have fashioned and decorated the pots.

Textiles. The same type of specialization is also implied in the making of textiles. Early protective garments were derived from animal skins. The development of agriculture cut into the supply of available skins and required a substitute material for clothing. To make textiles, yarn had to be spun; the earliest apparatus for this work consisted of a spindle and a distaff (a forked stick holding the unspun fibres). The figurative usage of the term distaff to refer to a female possibly indicates sexual division of labour in the early spinning process, with the man operating the spindle and the woman holding the distaff.

Agriculture. Primitive agriculture, too, may have dictated a division of work along sexual lines, with the fields entrusted to the women while the men hunted. In some agricultural tasks, however, such as clearing land, the men doubtless helped. Possibly there was little full-time specialization; in its beginnings, agriculture was carried on part-time. Yet even in its earliest stages agriculture was significant to the organization of work, for it provided a slight surplus that could be used to support the first real specialists: makers of metal tools and weapons.

Metallurgy. Although the origins of metallurgy are as yet unclear, employment of copper tools and weapons on a substantial scale suggests a new organization of work in which some persons devoted their full time to mining, smelting, and forging. Although deposits of flint for stone tools and weapons were fairly widely and evenly distributed, copper ores were not. Some of the earlier copper artifacts and remains of early copper mines have been found in areas where climate and topography would render agriculture difficult if not impossible. Geography thus dictated that the earliest miners and metalworkers could not be part-time agriculturalists but had to specialize. Besides, the techniques of prospecting, mining, smelting, casting, and forging were probably so demanding of physical strength and mental concentration as to preclude the metallurgist from farming or hunting activities.

Specialists in metalworking

Because copper ores are generally located in mountainous regions, the metal had to be transported to its users. Thus, metalworkers and their families had to be supported by the surplus foodstuffs of farmers; only when agriculture had developed beyond the subsistence level could such specialists survive. Not surprisingly, metallurgy developed first near the irrigation-farming valleys of the great river systems of the Nile, Tigris-Euphrates, and Indus, all of which provided a high yield of foodstuffs per acre. If metalworkers pursued their occupations full-time, their existence also implies other craft specialties. The combination of agricultural surpluses with copper and bronze tools provided the basis for development of the great irrigation civilizations of the Middle East. There the organization of work developed along lines that remained unchanged for the next 5,000 years, until the beginnings of mechanization and industrialization in the 18th century.

THE ANCIENT WORLD

The first general theory advanced to explain the development of ancient civilization with systematic organization of work on a large scale, the emergence of social classes, and widespread specialization was elaborated in the United States by the historian and political scientist Karl Wittfogel in his seminal book *Oriental Despotism* (1957). Wittfogel believed that the development of irrigation works in such areas as Mesopotamia and Egypt led to the use of mass labour, to an organizational hierarchy for coordinating and directing its activities, and to government control for ensuring proper distribution of the water. Though tribal societies had had some form of government, this was usually personal in nature, exercised by a patriarch over a tribal group related by various degrees of kinship. Now, for the first time, an impersonal government as a distinct and permanent institution was established.

Irrigation increased the food supply, allowing larger numbers of people to agglomerate into towns and cities. Because farmers were vulnerable to attack, armies were needed, with the implication of an officer class. Town specialization of labour brought the emergence of potters, weavers, metalworkers, scribes, lawyers, and physicians, while the new surpluses also created the basis for commerce. The more complex economy required records; so writing, of which the first examples come from the bookkeeping records of the warehouses in ancient Mesopotamia, was born.

Wittfogel's theory has been modified by scholars who point to the emergence of urban civilizations in some areas without the presence of large-scale irrigation works. In their view, several factors, including geographic features, natural-resource distribution, climate, kinds of crops and animals raised, and relations with neighbouring peoples, entered into the response to the environment. These scholars might be said to apply a "systems" approach to the interpretation of the origins of organized societies.

Social classes. In any case, by the time written history began, distinct social and economic classes were in existence, charged with identifiable functions. At the apex of the social pyramid stood the ruler and the nobles, probably grown out of a warrior group that had subjugated their neighbours. Closely aligned with them were the priests; often, as in Mesopotamia and Egypt, the ruler was worshiped as a divinity. Possessing knowledge of writing and mathematics, the priests served as government officials, organizing and directing the economy and overseeing clerks and scribes. Occupying a rung in the hierarchy between the noble-priest class and the peasants were the traders and merchants, who distributed and exchanged goods produced by others. A sizable group of artisans and craftsmen, producing specialized goods, belonged economically to the lower classes. At the bottom of the social scale were the slaves, originating as war captives or ruined debtors. The social structure in classical Greece and Rome continued to follow these lines. For relatively short periods of time republican or democratic governments did away with the ruling group, substituting a class of free landholders and providing a citizen army of warriors, but the basic economic organization remained unchanged.

Certain characteristics of the ancient organization of

work emerged from the rigid social stratification described above. Chief among these was the hereditary nature of occupations and status. At certain times and places—in the later Roman Empire, for example—heredity of occupation was enforced by law, but tradition was usually sufficient to maintain the system. The social structure remained remarkably stable, a tendency fortified by the organization of workers engaged in the same occupation, either voluntary or with the sanction of the law, that were the prototypes of the medieval guilds.

Agriculture. *The family farm.* The basic agricultural work unit in the ancient world was the family. Even in certain regions where the state owned the land, farms were allocated by family. Furthermore, when large farming estates were formed during the Roman Empire, the structure of rural society was little affected, because the owners commonly left cultivation of their land to peasants who became their tenants.

Work within the family farm unit was divided along sexual lines: the men bore chief responsibility for such seasonal tasks as plowing, sowing, tilling, and harvesting, while the women prepared food and made clothing. Sons and daughters were apprenticed to their parents, and, if slaves were available, their work was similarly divided.

Technology and the seasonal nature of agriculture also influenced work organization. The usual draft team in antiquity, a pair of oxen, required two operators: a driver for the team and a guide for the plow. During planting and harvesting, the entire family performed fieldwork.

Estates. In the large estates, or latifundia, of the Roman Empire, the organization of work was quite complex, and a hierarchy of supervisors came into existence. The Greek historian Xenophon (5th–4th century BC) and the Roman statesman Marcus Porcius Cato (3rd–2nd century BC) wrote handbooks for management of such estates. Cato also outlined the work organization for a medium-sized farm. For an estate of 150 acres (60 hectares) with olive trees he recommended an overseer, a housekeeper, five farmhands, three carters, a donkey driver, a swineherd, and a shepherd. To these 13 on the permanent labour force, extra hands would be added for the harvest period. On the larger latifundia that developed from about the 2nd century BC, the owner was usually nonresident, often because he had many scattered estates. Direction of the affairs of each was left in the hands of a bailiff under whose command slaves, numbering in the hundreds or even in the thousands, were divided into gangs charged with different responsibilities.

Crop specialization. Ancient agricultural work was also characterized by specialization in crops. Greece and Italy concentrating on the vine and the olive, with cereals being cultivated on the richer soils of Sicily, North Africa, and Asia. Wine and oil required craftsmen to produce amphorae for storage and conveyance, as well as tradesmen and small sailing vessels for transport.

Crafts. Economic growth, sophistication of taste, and enlarged markets ultimately brought mass production of a sort, with large workshops dedicated to production of a single item. These workshops, however, never achieved the size of even a small modern factory; craft production throughout antiquity remained distinctly modest in scale; a building in which a dozen persons worked was considered a large factory, though a few workshops were larger.

The earliest specialized craftsmen were probably itinerant, gravitating to wherever their services were in demand. As the market grew, craftsmen became sedentary, and traders carried their products to market. Economic growth also led to a multiplication of specialized crafts, to the organization of guildlike groups, and to a geographic division of labour, with members of one craft located in a special quarter of a city or in one area of a country. In the pottery industry, specialization was carried even further, with shaping, firing, and decoration sometimes done in separate establishments and with workshops specializing in cooking pots, jars, goblets, and funerary urns.

As ancient workshops grew in size, slaves were introduced. The chief examples of large-scale production by slaves were in mining and metallurgy, in which working conditions were especially harsh but in which work or-

ganization was refined. In the silver mines at Laurium, in ancient Greece, the master miner commanded three gangs of labourers. The strongest handled picks at the ore face, weaker men or boys carried ore from the mine, and women and old men sifted the ore-bearing rock. The miners worked 10-hour shifts (followed by 10 hours of rest) in dark and narrow passages with smoky lamps that made the air almost unbreathable. On the surface, the master smelter supervised the workshops, in which the strongest men worked the mortar and the weakest the hand mill. Metallurgical working of the ore was carried out by small units, because the small leather bellows limited the size of the furnace. Metallurgy thus remained essentially a handicraft.

After weapons and tools, the chief use of metal was for ornamentation. The metalworker was more artisan, or even artist, than industrial worker, and in the trade there were patternmakers, smelters, turners, metal chasers, gilders, and specialized goldsmiths and silversmiths.

Large-scale building. The monumental public-works projects of the ancient world demonstrate a remarkable degree of organization in the absence of power and machinery. The Great Pyramid of Giza, built about 2500 BC, before the Egyptians knew the pulley or had wheeled vehicles, covers 13 acres (5.3 hectares) and contains the staggering total of 2,300,000 colossal blocks of granite and limestone weighing an average of 5,000 pounds (2,300 kilograms). There exists no complete historical or archaeological record of the exact methods of quarrying, transportation, and construction of the pyramids, and what evidence remains is often contradictory. Obviously, however, the need to organize the work on a systematic and rational basis was superbly met. It is estimated that some 100,000 workers were involved over 20 years in building the Great Pyramid, and the logistic problem alone, housing and feeding this large army of workers, required a high degree of administrative skill.

The master builder, who planned and directed the erection of the pyramids and other great structures, occupied a high position in society. Ancestor of the modern architect and engineer, he was a trusted court noble and adviser to the pharaoh. He directed a team of subordinates, superintendents, and foremen, each with his scribes and recorders.

Although some slaves were employed in building the pyramids, most of the builders were peasants, drafted as a form of service tax (corvée) owed the state and employed when the Nile was flooding their fields. Workers were not regarded as expendable; overseers and foremen took pride in reporting on their safety and welfare. In a record of a quarrying expedition to the desert, the leader boasted that he had not lost a man or a mule. The labourers were organized into gangs: skilled workers cut granite for the columns, architraves, doorjambs, lintels, and casing blocks; masons and other craftsmen dressed, polished, and laid the blocks and probably erected ramps to drag the stones into place.

The Greeks and Romans used advanced organizational techniques in the building of monuments. The Roman road network, aqueducts, public buildings, public baths, harbours, docks, and lighthouses demanded exceptional skill in organizing materials and workmen, implying in turn a rational division of labour among craftsmen.

THE MEDIEVAL WORLD

The organization of work and division of labour may, in fact, be said to have reached a peak during the Roman Empire, but it inevitably declined as the empire disintegrated in the West. The social and political fragmentation and economic decay of the late empire reduced most of western Europe to small-scale, self-sufficient economic units. As this happened, the market for specialized production largely disappeared. As the new feudal society achieved stability, however, trade and town life began to revive; interregional commerce was stimulated, and specialized crafts reappeared to serve growing markets.

Important technological innovations in agriculture, power, transportation, metallurgy, and machines brought further areas of specialization into being. The emergence of the new burgher class, with rapidly growing wealth

and breadth of enterprise, provided the basis for a more rational management of production, hastening the rise of industrialization.

Class structure. Social divisions, or class structure, in the medieval world reflected a division of labour. The noble class, or seigneurs, were fighters, protectors, important consumers, and, in a sense, organizers of work. Because they controlled the land, basic to production in this agrarian society, the nobles alone possessed the wealth to purchase the products of artisans, to buy goods brought from a distance, to acquire the weapons and armour made by metallurgists, and to construct castles and fortresses. The lords also decided, in accordance with prevailing custom, how the farm work should be organized.

(margin note: Land-owning nobility*)*

The clergy were both consumers and producers, responsible for the spiritual care of their parishioners. The monasteries were self-sufficient agrarian units that often produced a surplus for trade; indeed, the monks experimented in improving farming techniques and in producing special cheeses and wines for an outside market. Finally, the great churches required specialists in stained glass, bell founding, stonemasonry, wood carving, and other trades.

The bulk of the population were farmers of varying legal status. Most were serfs bound to the plots of ground their ancestors had tilled and owing certain specified services and dues to the lord of the manor, who extended protection in return. A few inhabitants of the manor were tenant farmers, or sharecroppers, renting the lord's land in return for payments of a share of the produce. Fewer still were free farm labourers who worked for wages. Slavery had all but disappeared. Because the manor was practically self-sufficient, peasants of whatever status performed a variety of tasks connected with their agricultural occupation.

Agricultural production. Four interrelated factors determined the work organization of medieval agriculture: the economic self-sufficiency of the manor, the development of mixed agriculture based on crop growing and stock raising, such technological improvements as the heavy wheeled plow and rigid horse collar, and the system of land tenure and division of holdings. Each peasant household produced nearly everything it needed and paid for the use of a feudal-monopoly mill or winepress, not in money but by a percentage of the crop being processed.

In antiquity, stock raising and crop production had been separate enterprises. In northwestern Europe during the Middle Ages, the two were combined. Animals were needed both for draft and for food, and, because the yield of the grainfields did not greatly exceed human requirements, stock was pastured on poor land or harvested fields. Thus a certain amount of land was reserved for pasturage, and some villager, usually an older member of the community, became herdsman.

Communal organization was made imperative by the land-tenure arrangements and by the way in which arable land was divided among villagers. In a typical manor at least half the cultivable soil was held by peasant cultivators. In order to assure an equitable apportionment, the land was divided into large fields, each of which was subdivided into narrow strips. Each peasant held strips in each field; the work of plowing, planting, and harvesting, therefore, had to be done in common and at the same time.

(margin note: Communal crop farming*)*

The wheeled plow, gradually introduced over several centuries, further reinforced communal work organization. Earlier plows had merely scratched the surface of the soil, necessitating cross-plowing, which in turn made square fields desirable. The new plow was equipped with a heavy knife (colter) to dig under the surface of the soil and a moldboard to turn over the sod, eliminating the need for cross-plowing and making strip fields possible. On the other hand, because the new plow required a team of eight oxen, more than any single peasant owned, plowing (and indeed all heavy work on the manor) was pooled. Of course, such a system allowed little room for individual initiative; everyone followed established routines, with the pace set by the slowest oxen.

Industrial production. *The craft guilds.* In contrast to the land-bound serfs, townspeople of the Middle Ages were free. Some engaged in commerce, including long-distance trade, and formed corporate bodies known as

(left margin notes: Building the Great Pyramid*)*

Master, journeyman, and apprentice

merchant guilds. The majority, however, were small merchant-craftsmen, organized in craft guilds as masters (of highest accomplishment and status), journeymen (at a middle level), and apprentices (beginners). The medieval master was typically many things at once: a workman himself, the most skilled in his shop; a foreman, supervising journeymen and apprentices; an employer; a buyer of raw or semifinished materials; and a seller of finished products. Because medieval craftsmen employed simple hand tools, the skill of the workman rather than his equipment determined the quantity and quality of his output. Hence, there was a long period of learning for the apprentice and journeyman. At first the training was by "show and tell" and then "learning by doing" under the guidance of a more experienced workman. When a "masterpiece" could be produced that would receive the approval of the guild masters, the craftsman gained full admission into the guild.

The essence of craft-guild organization was regulation. By controlling conditions of entrance into a craft, guilds limited the labour supply. By defining wages, hours, tools, and techniques, they regulated both working conditions and the production process. Quality standards and prices were also set. Monopolistic in nature, the guilds, either singly or in combination, sought complete control over their own local markets and endeavoured to exclude outsiders. In order to attain and protect their monopoly, the guilds acquired a political voice and in some locations achieved the right to elect a number of their own members to the town council. In some towns, such as Liège, Utrecht, and Cologne, guilds achieved complete political control. The 32 craft guilds in Liège, for example, so dominated the town after 1384 that they named the town council and governors and required all important civic decisions to be approved by a majority vote of their membership.

The most prosperous period for the craft guilds was the 14th century. Specialties became so differentiated that there were more than 100 guilds in large towns. In northern Europe, for example, at the beginning of the period, carpenters built houses and made furniture. In time, furniture making became a new craft, that of joinery, and the joiners broke from the carpenters to establish their own guilds. The wood-carvers and turners (who specialized in furniture turned on a lathe) founded guilds also. Painting and gilding of furniture and wood carvings were done by members of the painters' guild.

Simultaneously, there was a countermovement toward amalgamation of different crafts, a tendency that reflected the growth of the market and the desire of enterprising masters to develop the trading function at the expense of the handicraft function. The typical medieval craft regulation had as its objective for each craftsman to gain an equal share in the trading function, a monopolistic division of the market. As craft differentiation reached a point at which a number of crafts participated in the production of the same or similar articles, such conditions could not be maintained. The steadily widening search for raw materials and steadily growing marketplace stimulated craftsmen at each end of the production chain to concentrate on trade, to assure themselves either of raw materials or of a market. In either case, masters were tempted to employ members of other crafts, and conflicts inevitably arose.

The same widening of the market led to differentiation of classes within a craft. The trading function acquired increasing importance and also came to be exercised by certain individuals within a single craft organization; those who remained craftsmen fell into a condition of dependence upon the traders. At the same time, merchant guilds, originally representatives of traders only, absorbed the craft guilds, over which they had gradually acquired economic control.

Internally, too, the craft guilds suffered a breakdown in structure. Because the masters sought to retain the profits of the growing market for themselves, they made it increasingly difficult for journeymen to enter their class,

From craftsman to wage earner

preferring instead to employ them as wageworkers. Apprentices similarly had little hope of rising to mastership. Thus the master–journeyman–apprentice relationship gave way to an employer–employee arrangement, with the

master performing the functions of merchant while his employees did craftwork. Conditions for development of the early industrial system—the proto-factory—thus arose with the disintegration of the original craft-guild system. The excluded journeymen eventually became a class of free labourers who practiced their craft for wages outside town walls where guild regulations did not reach.

The putting-out system.   Certain industries that were small at the outset of the Middle Ages had by their close become large in scale, with accompanying changes in the organization of work. The most important of these was the wool-cloth industry.

The basic clothing material in western Europe until the beginning of modern times was wool. Linen and silk, though used since antiquity, were too costly to become raw materials for any large-scale industry until a later date, and cotton was grown only in small volume. The production of cloth from wool involved several time-consuming steps: cleaning and carding (straightening curled and knotted fibres sheared from the sheep), spinning the fibres into thread, weaving the thread into cloth, shearing off knots and roughness, and dyeing. All these processes could be carried on within a single peasant household, for they required only simple apparatus and rudimentary skills. Children carded the wool; women operated the spinning wheel; and men worked the loom shuttles.

The cloth produced by such crude tools and relatively unskilled workers was rough but serviceable. Those above the peasant class, however, wanted more comfortable and attractive clothes that could be produced only by skilled craftsmen. Thus a large and growing demand existed for better textiles, and the industry rapidly outgrew the peasant household economy. A new organization of work, called the putting-out system, was instituted, in which a merchant clothier bought raw wool, "put it out" to be carded, spun, and woven into cloth, and then carried the cloth through the finishing processes with the help of skilled craftsmen. Because the spinners and weavers remained peasants, they earned part of their living from the plots on which their cottages stood; agriculture and industry were carried on together as almost an integrated enterprise. The man could work in the field while his wife spun; in winter the man joined in industrial production. At harvesttime every hand was out in the fields, leaving spinning wheel and loom idle.

Early capitalist and worker

The putting-out system differed from peasant household production in that the merchant clothier, or entrepreneur, bought the raw wool and owned the product through its stages of preparation, although the cottage workers owned their own spinning wheels, looms, and other tools. Thus the peasant farmer came to work on materials that did not belong to him, and his position gradually changed to one of dependency. On the other hand, the work was performed at home (the cottage system, or domestic system) and at the worker's pace rather than in a factory under impersonal discipline. The merchant, furthermore, simply arranged the order and sequence of the various technical processes without exercising direct supervision over their actual performance. Nevertheless, the merchant clothier who began putting out cloth came to control the entire production process and represents a step toward the industrial capitalist of the 19th century.

Advances in technology.   Change in the scale of commerce through the establishment of large national markets was not the sole cause of changes in the organization of work during the Middle Ages. Equally important was the transformation caused by advancing technology, especially in the application of wind power and waterpower—the beginning of a long development in the replacement of human labour by machine power. From the late 10th century, waterwheels, long used for grinding grain, were applied to many industrial processes: tanning; olive pressing; sawing; armour polishing; pulverizing; operating blast-furnace bellows, forge hammers, and grindstones; and crushing mash for beer. The first horizontal-axle windmill appeared in western Europe in 1185, and within a short time windmills spread from northern England to the Middle East.

A good example of the change in industrial organization

created by the application of waterpower to an industrial process is the fulling (*i.e.*, shrinking and thickening) of cloth, a process that was mechanized in the 13th century. Previously fulling had been accomplished by trampling the cloth or beating it with a fuller's bat, processes dating back to antiquity. The fulling mill invented during the Middle Ages was a twofold innovation: first, two wooden hammers replaced human feet; and second, the hammers were raised and dropped by the power of a water mill. A series of hammers could be set to work with only one man needed to keep the cloth moving properly in the trough, which was filled with water and fuller's earth. The mechanization of fulling also changed the organization of work indirectly by causing the cloth industry to relocate along streams, often away from the former urban textile centres, thus bringing a relaxation of old institutional constraints.

Perhaps the best example of specialization of labour in the Middle Ages is to be found in the large-scale metal-mining industry in central Europe, as described by the German scholar and man of science Georgius Agricola in *De re metallica* (1556), the leading textbook for miners and metallurgists for nearly two centuries. In addition to the *Bergmeister* ("master miner"), the chief mine administrator, there was a hierarchy of clerical and technical personnel and a series of craftsmen and mechanics specializing in different phases of the mining operation: miners, shovelers, windlass operators, carriers, sorters, washers, and smelters. The mines operated five days a week on a 24-hour basis, with the workday divided into three seven-hour shifts and the remaining three hours used for changing shifts. Animal power was used wherever possible, with teams of eight horses hitched in pairs to turn windlasses and raise buckets of ore or drain water from the mine. Agricola's illustrations show many types of pumps for mine drainage: crank-operated, treadmill-operated, and waterpower-operated. There were also suction pumps of varying degrees of complexity. All were operated by specialized mechanics.

The bellows for mine ventilation were also operated either by human and animal power or by waterpower. Other mining processes were less mechanized and were carried on much as they had been in antiquity. Ores brought to the surface were taken to a sorting table on which women, boys, and old men sorted the pieces by hand, putting the good ores into wooden tubs to be carried to the furnaces for smelting.

Monumental construction. The mechanization that was changing the organization of work in large-scale industries throughout the medieval period was little apparent in the construction of castles, cathedrals, and town walls. The technology involved in the lifting of weights, for instance, had made little progress during the Middle Ages, and, because the freemasons declined to handle large blocks of stone, the Romanesque and Gothic structures were built with smaller stone blocks, nevertheless achieving grandeur in scale. The organization of labour differed greatly from that employed in antiquity. These great monuments were the first in history to be built by free labour including, carpenters, glaziers, roofers, bell founders, and many other craftsmen, besides the stonemasons.

Freely contracted labour

The free and unfettered nature of medieval construction as compared with that of antiquity can be seen both in the works themselves, which reveal a high degree of individualism, and in the records. For a long time it was believed that medieval craftsmen, especially those engaged in the building of cathedrals, were humble, self-effacing artisans who laboured piously and anonymously for the glory of God and for their own salvation. The industry of scholars has dispelled this myth. Medieval builders often left their names or signatures upon their work, and surviving records show names, wages, and occasionally protests over wages. The artisans were by no means anonymous: historians have uncovered more than 25,000 names of those who worked on medieval churches.

Directing the guild craftsmen was the master mason, who, like his ancient counterpart, functioned in many capacities: architect, administrative official, building contractor, and technical supervisor. He designed the molds, or patterns, used to cut the stones for the intricate designs

of doors, windows, arches, and vaults. He designed the building itself, usually copying its elements from earlier structures upon which he had worked as a master or during his apprenticeship. He sketched his plans out on parchment. As administrator he kept the accounts, hired and fired the workers, and was responsible for procurement of materials. As technical supervisor he was constantly on the job for spot decisions and planning. In the largest projects he was assisted by undermasters.

The proliferation of industry during the early modern period—that is, from the 16th to the 18th century, immediately preceding the Industrial Revolution, properly so called—arose from four factors: (1) the growth of wealth, derived partly from the influx of precious metals from the New World and from growing commercial and banking activities; (2) the growth of demand, or markets; (3) the introduction of new products; and (4) the development of new technology. The result was an increase in the scale of manufacturing industry throughout Europe, accompanied by changes in the organization of work.

The growth in the size of the market was caused only partially by the geographic explorations of the preceding era and subsequent colonization. Most of the new demand for goods came about as a result of a growing population, especially toward the latter part of the 17th century and beginning of the 18th century, and a rise in the standard of living, especially among the class of burghers, or bourgeoisie—the town dwellers. The markets also grew in size with the replacement of the small medieval feudalities by larger political units—the royal kingdoms. When economic sway was exercised over a larger jurisdiction, it tended to eliminate many of the local restrictions on trade and commerce established by the previous smaller political units. Many new products—including spices from Asia and sugarcane from the New World—were also introduced into Europe, either directly, by the explorers, or indirectly, through expanded trade with distant points. The demand continued to increase along with the growing affluence and new manners of living in European society. Handicraft production no longer sufficed, and the guilds declined.

Beginnings of the factory system. The changes in industrial patterns that emerged were less in the introduction of new mechanical contrivances than in the growth in extent of the application of power, primarily water and wind, to old devices and, even more significant, in the organization of work to meet the needs for production on a larger scale—the beginnings of the factory system.

Production on a large scale

The proto-factory of the 17th and 18th centuries centred in certain industries, especially textiles. The old guild corporations broke down, and the cottage system began giving way to larger units of production. The organization of commerce changed rapidly. New instruments in the fields of banking, insurance, and export marketing helped to amass capital and make it available for investment in industrial enterprises. In this movement toward the capitalization of industry, some of the lesser masters were driven down into the wage-earning class, while greater masters became capitalist employers.

In Britain the development of commercial concentration—and hence of industrial scale—was mainly the work of large companies or corporate bodies, such as woolen manufacturers, ironmasters, and hatmakers. Government encouragement was given by means of special legislation, especially grants of monopolistic charters. In France, however, the practice of mercantilism, a government-directed policy aimed at increasing national wealth and power, meant that the government itself took an active part in developing industries that were state owned and operated, among them the famous Gobelins tapestry works and the manufactories for production of furniture, porcelain, and other luxury items.

Although the state-run factories in France represented at least two of the essentials of factory production—the gathering of large groups of workers in one place and the imposition of disciplinary rules—they had little effect upon the organization of work because they produced

small quantities of luxury goods and hence amounted to large handicraft operations. Furthermore, despite their size, the French Royal Manufactures did not possess the third prime element of a true factory system: mechanization. The great historical change in the organization of work came in 18th-century Britain with the onset of the Industrial Revolution, largely as the result of the new technology of power-driven machinery.

The **Industrial Revolution.** *Mechanization.* The new machines introduced in the 18th century compelled a rational organization of job functions that was quite different from the old handicraft tradition. Adam Smith in *The Wealth of Nations* (1776) gave the classical description of the new production system as exemplified by a pin factory: "One man draws out the wire; another straights it; a third cuts it; a fourth points it; a fifth grinds it at the top for receiving the head; to make the head requires two or three distinct operations; to put it on is a peculiar business; to whiten the pin is another; it is even a trade by itself to put them into the paper; and the important business of making a pin is in this manner divided into about 18 distinct operations." According to Smith, a single worker "could scarce, perhaps with his utmost industry, make one pin in a day, and certainly could not make 20." The new methods enabled a pin factory to turn out as many as 4,800 pins a day.

The great increase in productivity depended far more upon the rational organization of processes than upon individual skill. In the textile industry manual dexterity and alert response proved to be more valuable than experience, accounting for the use of inexpensive woman and child labour in the early mills. Some vestiges of the medieval guild apprenticeship, however, still remained in the early textile factories; the children were sometimes bound as apprentices for a period of at least seven years, usually until they were 21. In some areas the old cottage system of textile production was moved to the factory, with the entire family employed as a work team. In those cases the father would be employed for any heavy work while supervising his wife and children at the machines. Presumably the father also possessed the mechanical skills necessary to repair and maintain the machinery.

Division of labour in the workplace. Because machines could justify their high cost only if a heavy and continuous demand existed for their output, their presence led to a division of labour between the entrepreneur who owned them and his employees. The owner supervised his workers, compelling them to work at the pace of the machine. Even in enterprises that were not yet fully mechanized, the advantages of factory discipline were apparent at an early stage of the Industrial Revolution. Josiah Wedgwood designed his pottery works at Etruria in England "with a view to the strictest economy of labour." His plant was laid out so that the pots were first formed and then passed through the painting room, the kiln room, the account room, in which an inventory of production was made, and finally to storage. In potteries before this time, the workers could wander from one task to another; in Wedgwood's, the employees were assigned a particular post and worked at one task only. Out of 278 men, women, and children employed by Wedgwood in 1790, only five had no assigned post; the rest were specialists.

While the argument is sometimes made that the division of labour destroyed skill, the fact is that it might also have improved the quality of the finished product, for Wedgwood's pottery was superior to that of his competitors. It can be said that the division of labour does not so much destroy skill as limit it to a particular field of expression; and, within that particular task, it increases skills by continued repetition. It is interesting to note that Wedgwood's chief difficulty was not so much in training his workers as it was in introducing them to a novel form of discipline that ran contrary to centuries of independence. It was a constant test of Wedgwood's ingenuity to enforce six hours of punctual and constant attendance upon his workers, to get them to avoid waste, and to keep them from drinking on the job and taking unauthorized "holidays." Because he was a busy man involved in all the tasks of running an enterprise and could not stand over his workers and

[margin note: Factory discipline]

control their movements, he had to develop a hierarchy of supervisors and managers.

There can be little doubt that the condition of the workers, especially the women and children, in the early textile factories was miserable: 14 to 16 hours every day spent performing repetitive tasks in noisy, smelly, and unsanitary surroundings; and the workers' slum homes were equally unhealthy. It was at this period that the "social question" arose: why should poverty continue to exist in a nation that had the capacity to produce enormous quantities of goods? Answers to that question were to produce new social philosophies and political movements that have had major effects on society and politics ever since.

New industries. The introduction of steam-driven machinery at the time of the Industrial Revolution brought new industries into being or transformed older ones. This was especially true of the metalworking trades, where technological innovations made possible the replacement of wooden machinery with metal and the manufacture of such items as metal nails, glassware, and iron bearings. Expansion of manufacturing helped to stimulate the coal-mining industry. Coal was replacing wood as a fuel especially in England and northern France, where deforestation had made wood scarce. The pressure on fuel supplies came not only from domestic heating requirements and from the metallurgical trades but also from the brickmaking, brewing, dyeing, and glassmaking industries. In the coal mines the organization of labour remained much as it had been described by Agricola in the 16th century.

Another spur to the rise of new industries was the religious warfare of the 16th and 17th centuries. The forced movement of populations helped spread technical capabilities to new areas. For example, the Protestant Huguenots, expelled from France near the end of the 17th century, carried with them their special skills in metalworking and glassmaking when they migrated to England, Holland, Germany, and the American colonies.

[margin note: Spread of technology]

Urbanization. One of the greatest stimuli toward a more rational organization of work was the general demographic trend in Europe from the 17th to the 19th century. Population grew swiftly, moving from country to city. It is possible that only a few European cities—Paris and the great Italian commercial cities of Venice, Genoa, and Naples—had as many as 100,000 people at the beginning of the modern era. London may have had only about half that number. By the beginning of the 17th century, however, rapid growth had begun, and, by the end of that century, London probably had 500,000 inhabitants.

Colonization of the New World. *Worldwide division of labour.* Although exploration and colonization had originally been carried out in order to secure exotic and expensive spices, these products had little direct influence upon the organization of work in Europe; even the enormous trade in semitropical items such as sugar and coffee had little effect. However, wheat, wool, and meat from the temperate areas ultimately brought about an international division of labour, with the New World colonies furnishing agricultural produce to the manufacturing countries of Europe. In the 20th century such a division still exists in somewhat different form, with the underdeveloped nations of the tropics supplying agricultural and industrial raw materials to developed areas.

Slavery. In its effect on the organization of work, the most important result of the colonization of the New World and the demand for its products was the use of slave labour. Slavery was linked first with sugar production in the West Indies and later with cotton in southern North America.

Cultivation of sugarcane, especially its harvesting, requires heavy manual labour. Harvested cane must be sent to a mill for grinding within a few hours after cutting; this requirement necessitated establishment of a plantation system in which the workers would be housed close to the fields and the sugar mill. The natives of the West Indies were not numerous enough to perform the required work and were temperamentally unwilling to engage in such labour, even when harsh means were employed to force them to do it. The requirements of sugar planters thus introduced agricultural slavery into the Western Hemi-

[margin note: The plantation]

sphere. It began as early as 1518, when the Spanish government granted a license to import some 4,000 African slaves into the Spanish colonies. The plantation system and the consequent demand for African slaves spread during the next two centuries throughout the sugar-growing areas, including the British West Indies. Indeed, the British islands of the West Indies carried specialization in sugar so far that they found it most profitable to devote nearly all their land to the export crop of sugarcane and to import other foods.

In the temperate zone, where sugar production was not possible, slaves were little used except in tobacco-growing areas until near the end of the 18th century. The Puritan communities in New England engaged in small family farming, while the Southern colonies employed indentured servants (white labourers who agreed to work a number of years for some person who had paid their passage to the New World).

Eli Whitney's invention of the cotton gin in 1793 lowered the price of upland cotton and led to the use of that fibre as a staple for textile production. As a result, Negro slavery and the plantation system became fixtures in the American South. While slaves were employed chiefly as cotton-field labourers, they also worked as craftsmen, factory hands, and domestic servants, creating, in other words, a division of labour on the plantation. The regional specialization in production led to sectional economic and political differences and ultimately to the American Civil War and to the freeing of the slaves.

Organization of work in the industrial age

THE COMING OF MASS PRODUCTION

Mass production is the name given to the method of producing goods in large quantities at low cost per unit. But mass production, although allowing lower prices, does not have to mean low-quality production. Instead, mass-produced goods are standardized by means of precision-manufactured, interchangeable parts. The mass production process itself is characterized by mechanization to achieve high volume, elaborate organization of materials flow through various stages of manufacturing, careful supervision of quality standards, and minute division of labour.

To make it worthwhile, mass production requires mass consumption. Until relatively recent times the only large-scale demand for standardized, uniform products came from military organizations. The major experiments that eventually led to mass production were first performed under the aegis of the military.

Industry. *Machine tools and interchangeable parts.* The material basis for mass production was laid by the development of the machine-tool industry—that is, the making of machines to make machines. Though some basic devices such as the woodworking lathe had existed for centuries, their translation into industrial machine tools capable of cutting and shaping hard metals to precise tolerances was brought about by a series of 19th-century innovators, first in Britain and later in the United States. With precision equipment, large numbers of identical parts could be produced at low cost and with a small work force.

American System of manufacture

The system of manufacture involving production of many identical parts and their assembly into finished products came to be called the American System, because it achieved its fullest maturity in the United States. Although Eli Whitney has been given credit for this development, his ideas had appeared earlier in Sweden, France, and Britain and were being practiced in arms factories in the United States. During the years 1802–08, for example, the French émigré engineer Marc Brunel, while working for the British Admiralty in the Portsmouth Dockyard, devised a process for producing wooden pulley blocks by sequential machine operations. Ten men, in place of 110 needed previously, were able to make 160,000 pulley blocks per year. British manufacturers, however, ignored Brunel's ideas, and it was not until London's Crystal Palace exhibition of 1851 that British engineers, viewing exhibits of machines used in the United States to produce interchangeable parts, began to apply the system. By the third quarter of the 19th century, the American System was employed in making small arms, clocks, textile machinery, sewing machines, and a host of other industrial products.

The assembly line. Though prototypes of the assembly line can be traced to antiquity, the true ancestor of this industrial technique was the 19th-century meat-packing industry in Cincinnati, Ohio, and in Chicago, where overhead trolleys were employed to convey carcasses from worker to worker. When these trolleys were connected with chains and power was used to move the carcasses past the workers at a steady pace, they formed a true assembly line (or in effect a "disassembly" line in the case of meat cutters). Stationary workers concentrated on one task, performing it at a pace dictated by the machine, minimizing unnecessary movement, and dramatically increasing productivity.

Drawing upon observations of the meat-packing industry, the American automobile manufacturer Henry Ford designed an assembly line that began operation in 1913. The result was a remarkable reduction of manufacturing time for magneto flywheels from 20 minutes to five minutes. This success stimulated Ford to apply the technique to chassis assembly. Under the old system, by which parts were carried to a stationary assembly point, $12^1/_2$ man-hours were required for each chassis. Using a rope to pull the chassis past stockpiles of components, Ford cut labour time to six man-hours. With improvements—a chain drive to power assembly-line movement, stationary locations for the workmen, and work stations designed for convenience and comfort—assembly time fell to 93 man-minutes by the end of April 1914. Ford's methods drastically reduced the price of a private automobile, bringing it within the reach of the common man.

Ford's spectacular feats forced both his competitors and his parts suppliers to initiate his technique, and the assembly line spread through a large part of U.S. industry, bringing dramatic gains in productivity and causing skilled workers to be replaced with low-cost unskilled labour. Because the pace of the assembly line was dictated by machines, the temptation arose to accelerate the machines, forcing the workers to keep up. Such speedups became a serious point of contention between labour and management, while the dull, repetitive nature of many assembly-line jobs bored employees, reducing their output.

Assembly-line speedups

Effects on the organization of work. The development of mass production transformed the organization of work in three important ways. First, tasks were minutely subdivided and performed by unskilled workers, or at least semiskilled workers, since much of the skill was built into the machine. Second, manufacturing concerns grew to such size that a large hierarchy of supervisors and managers became necessary. Third, the increasing complexity of operations required employment of a large management staff of accountants, engineers, chemists, and, later, social psychologists, in addition to a large distribution and sales force.

Mass production also heightened the trend toward an international division of labour. The huge new factories often needed raw materials from abroad, while saturation of national markets led to a search for customers overseas. Thus, some countries became exporters of raw materials and importers of finished goods, while others did the reverse. In the 1970s and '80s some countries, particularly in Asia and South America, that had hitherto been largely agricultural and that had imported manufactured goods began industrializing. The skills needed by workers on assembly-line tasks were easily acquired, and standards of living in these developing countries were so low that wages could be kept below those of the already industrialized nations. Many large manufacturers in the United States and elsewhere therefore began "outsourcing"—that is, having parts made or whole products assembled in developing nations. Consequently, those countries are rapidly becoming integrated into the world economic community.

Agriculture. Starting in the 19th century, agriculture underwent a transformation comparable to the change from handicraft to mass production in industry. At the beginning of that century, farming was primarily a family

enterprise, employing age-old techniques and organization of work. Despite some technological innovations, such as the plow and seed drill, output per man was relatively small. In the late 19th and especially in the 20th century, output per farmer increased rapidly until, in the most advanced countries, a small minority of farmers supplied entire populations with food. These great changes were brought about by a series of advances in science and technology, including improved power sources, mechanical devices such as the reaper and combine, a scientific approach to plant and animal breeding, better food processing and preservation, more effective fertilizers and pesticides, and application of industrial management techniques to agriculture.

Factory farms. The organization of work developed in mass production industries was not transferred intact to agriculture. The tasks involved in running a farm change in accordance with the cyclical nature of the growing process and may vary greatly among different crops. They depend also upon the degree to which a given farm has been mechanized. The outstanding example of factory-type production in agriculture is in the U.S. poultry industry. A computerized feed bin, programmed with the exact quantities of nutrients required for health and quick growth, mixes the feed and delivers it automatically to the cage in which the bird is confined throughout its life. Water is delivered automatically, and waste is removed by mechanical means. When the chicken reaches precisely the correct weight for processing, that task is performed on an assembly-line basis. Application of these techniques has sharply reduced the cost per pound of chicken, and a form of protein that was once a luxury has become a staple item of diet. Similar methods are used to raise veal calves and other meat-producing animals as well. Capital investment in such factory farms is high, and production is carried on by giant companies.

American poultry farming

Migrant labour. The industrialization of agriculture meant that the small farm was being replaced by larger units, and this had profound consequences for agricultural labour. In the small-scale enterprise that had prevailed since antiquity, the farm family, with perhaps a few hired hands, had done all the work of planting, tending, and harvesting the crop, with neighbours joining to help one another during peak working periods such as the harvest. But the advent of industrialization drew workers from the farms to the cities, and the increase in mechanization required fewer farm labourers on a year-round basis. There was still need, however, for many hands during planting and harvesting, especially for fruit and vegetable crops that matured at the same time and still required hand harvesting.

In the United States the need for seasonal farm workers has been met—especially in Florida, Texas, and California (where approximately half the nation's fruits and vegetables are grown)—by migrant workers, largely from Mexico, elsewhere in Latin America, and the Caribbean countries, although some native-born Americans continue to follow the harvesting season north as temporary labourers. Few city dwellers, however, have deserted the cities to work on farms.

The employment of these seasonal workers raises a number of social, political, and economic problems. Migrants are typically paid low wages with no fringe benefits. Their living and working conditions remain far below standard. In spite of this, they often look to migrant farm labour as a means of escaping the worse conditions of their native countries.

The demand for migrant labour decreases as mechanization increases. In the United States, for instance, the harvesting of wheat and cotton, which required the work of many migrants before World War II, is now largely mechanized and done by regularly employed farmhands. In mature economies migrant labour contributes little to total agricultural output and a negligible amount to non-agricultural output. Nevertheless, the availability at the right time and place of migrant workers can be crucial, as without them large crop losses may occur.

State-organized farming. Agricultural mass production takes many forms. In the former Soviet Union *sovkhozy,*

or state agricultural farms, were owned by the government. Farmers were, in effect, state employees. Soviet collective farms were in theory cooperative associations of farmers who combined their land and capital, sharing proceeds in common. Each family on a collective farm, however, was permitted to cultivate its own small plot of land.

Collective farms

Although the Soviets at first prided themselves on their communal organization of agriculture, it became evident that the system was not meeting productivity goals. Despite its fertile soil, the Soviet Union was forced to import agricultural staples such as wheat from capitalist nations. Most of the fruits and vegetables consumed in the former U.S.S.R. came from the owners of small private plots who were allowed to grow crops for their own profit and had greater incentives to bring more foodstuffs to the market.

Acknowledging the productive capacity of private initiative, the Soviet government in the 1980s began to loosen the constraints of collective agriculture. In 1989 individual farmers were given the opportunity to lease land and equipment. The lessee could decide what to produce and at what price to sell it. Furthermore, children could "inherit" the leased property. With the demise of the Soviet Union that same year, agriculture in Russia and the other former Soviet states became increasingly privatized. Because so much of Russia's farmland is still held collectively, however, agricultural productivity is far below the standards of most other countries.

The situation in the People's Republic of China initially paralleled that in the U.S.S.R. Mass collectivization took place during Mao Zedong's Great Leap Forward of 1958–60. The resulting disorganization of the agricultural system led to a famine that is thought to have caused 20 million to 30 million deaths. Productivity surged during the 1980s and '90s, when peasants were allowed to own or lease land and market their own agricultural products. This contributed to a rise in the standard of living in rural areas.

Services. For most of recorded history, the vast majority of the world was engaged in farming. Beginning in the 19th century, industrial employment took primacy over agricultural work in those countries that had successfully industrialized. By the 21st century, the service sector came to represent the fastest-growing area of the work force in the world's most advanced economies. In the United States, for example, as early as the 1950s the number of people engaged in service occupations exceeded the number of those employed in industry, and the proportion increased thereafter.

Work in the service sector is highly diverse, including everything from janitors to business consultants, from truck drivers to financiers, from fast-food waiters to maîtres d'hôtel, from office clerks to advertising executives, from kindergarten teachers to university professors, from nurse's aides to surgeons, and government employees ranging from street sweepers and garbage collectors to legislators and heads of government.

Within the service sector, employment trends and working conditions changed throughout the 20th century. For example, the number of domestic servants declined drastically, with full-time, live-in domestic help almost disappearing and even part-time day servants also declining greatly. On the other hand, the number of government employees grew dramatically as government entities, from local to regional to national, took on tasks formerly ignored or left to the private sector.

SOPHISTICATION OF MASS PRODUCTION

Scientific management. According to Henry Ford, the assembly line was based on three simple principles: "the planned, orderly, and continuous progression of the commodity through the shop; the delivery of work instead of leaving it to the workman's initiative to find it; an analysis of operations into their constituent parts."

American industrial engineer Frederick W. Taylor (1856–1915) led the development of an entirely new discipline—industrial engineering, or scientific management. In this approach, the managerial functions of planning and coordination were applied throughout the productive process.

Taylor believed that a factory manager's primary goals were to determine the best way for the worker to do the

The engineering view of Frederick Taylor

job, to provide the proper tools and training, and to provide incentives for good performance. He broke each job down into its constituent motions, analyzed these to determine which were essential, and timed the workers with a stopwatch. With superfluous motion eliminated, the worker, following a machinelike routine, became much more productive. In some cases, Taylor recommended a further division of labour, delegating some tasks, such as sharpening tools, to specialists.

These studies were complemented by two of Taylor's contemporaries in the United States, Frank B. and Lillian M. Gilbreth, whom many management engineers credit with the invention of motion studies. In 1909 the Gilbreths, studying the task of bricklaying, concluded that much motion was wasted by the worker in reaching down to pick up each brick. They devised an easily adjusted scaffold that eliminated stooping and improved average work performance from 120 to 350 bricks per hour. Industrial engineering ultimately came to include all elements of factory operation within its compass—layout, materials handling, and product design, as well as labour operations.

Taylor regarded his movement as "scientific" because he attempted to apply scientific principles and measurement to the work process. Many previous advances in manufacturing had been made by applying scientific principles to machines in order to make them more efficient, and, through his minute subdivision of labour, Taylor sought to do the same to the work process itself. This scientific approach, however, neglected the human element, so that Taylor in effect converted the work process from a relationship between worker and machine into a relationship between two machines.

Scientific management theorists assumed that workers desired to be used efficiently, to perform their work with a minimum of effort, and to receive more money. They also took for granted that workers would submit without question to standardization of physical movements and thought processes. Their system, however, ignored human feelings and motivations, leaving the worker dissatisfied with the job. Furthermore, some employers omitted the altruistic elements in Taylor's system and employed time and motion studies to set high norms of production and speed up the production line while still keeping wages down.

Industrial psychology. Unions became the mouthpiece for those who opposed some of the consequences of scientific management. This was especially true in the decade after 1910, when the principles of scientific management were being applied wholesale in U.S. industry. Though the unions approved more efficient production arising from better machinery and management, they condemned the speedup practice and complained in particular that Taylorism deprived workers of a voice in the conditions and functions of their work. Complaints were also made that the system caused irritability and fatigue along with physiological and neurological damage among workers. Misuse of the human element in production was causing declines in both quality and productivity. Industrial engineers then faced the problem of motivating the worker so that the combination of human labour and machine technology would achieve its fullest potential. A partial solution came from the social sciences, and, in the process, industrial psychology emerged.

The major premise of this new discipline was that mass production technologies affect the worker both in the immediate job environment and in relations with fellow workers and supervisors. The first important discoveries in the social context of mass production technology resulted from experiments made by the American social scientist Elton Mayo between 1927 and 1932 at the Hawthorne plant of the Western Electric Company, in Cicero, Ill. Mayo, who earlier had studied problems of physical fatigue among textile workers in a Philadelphia plant, was called in to the Hawthorne works, where industrial engineers were considering the potential effect on productivity of changes in illumination. The investigators chose two groups of employees working under similar conditions to produce the same part; the research plan was to vary the intensity of the light for the test group but to keep it constant for the control group. To Mayo's surprise, the output of both groups rose. Even when the researchers told one group that the light was going to be changed and then did not change it, the workers expressed satisfaction, saying that they liked the "increased" illumination, and productivity continued to rise.

Mayo saw that the significant variable was not physiological but psychological. A second series of experiments was performed, involving the assembly of telephone relays; test and control groups were subjected to changes in wages, rest periods, workweeks, temperature, humidity, and other factors. Output continued to increase no matter how physical conditions were varied; indeed, even when conditions were returned to what they had been before, productivity remained 25 percent above its original value. Mayo concluded that the reason for this lay in the attitudes of the workers toward their jobs and toward the company. Merely by asking their cooperation in the test, the investigators had stimulated a new attitude among the employees, who now felt themselves part of an important group whose help and advice were being sought by the company. The name Hawthorne effect was given to such beneficial changes in workers' attitudes and, within a short time, scientific management incorporated these new findings.

The Hawthorne effect

Mayo's studies had suggested that consultation, usually in the form of interviews between labour and management, gave workers a sense of belonging to a team. Industrial engineers and sociologists have suggested additional approaches toward improving motivation and productivity. These include job alternation to relieve boredom; job enlargement, or having the worker perform several tasks on a project rather than performing a single operation; and job enrichment, redesigning the job to make it more challenging.

In a sense, Mayo's work made scientific management even more scientific, because he brought the new behavioral sciences, like social psychology, into the problems of organizing work and the labour–management relationship. It encouraged the development of human-factors engineering and ergonomics, disciplines that attempt to design "user-friendly" equipment accommodating itself to the human physiology and nervous system. For example, the new engineers try to make certain that a worker's equipment is operable with minimum strain, at a comfortable work level, and with controls easy to reach, see, and manipulate. In brief, they attempt to design the machine around the human mind and body.

AUTOMATION

The logical ultimate in the evolution of mass production processes is automation. In its ideal form, automation implies elimination of all manual labour and the introduction of automatic controls, assuring accuracy and quality beyond human skills. Perfect automation has never been attained, but sufficient equipment has been installed in many industries to alter greatly the pattern of employment. Tasks formerly performed by machine operators on a production line have come to require only maintenance personnel, engineers, office employees, production-control specialists, and some others. Although automation has been described as a "revolutionary" development, it is actually the end result of the trend of mechanization that began with the Industrial Revolution.

The word automation was coined in the 1940s at the Ford Motor Company and was first applied to the automatic handling of parts in metalworking processes. The concept acquired broader meaning when the American mathematician Norbert Wiener wrote about cybernetics, which he defined as control and communication in the animal and the machine. Wiener anticipated the application of computers to a number of manufacturing situations. His prediction that the introduction of automatic machinery would swiftly give rise to mass unemployment was popularized during the 1950s and '60s, causing considerable alarm. But automation was not introduced as rapidly as foreseen, and other economic factors have intervened to lessen the displacement of labourers.

Automation evolved from three interrelated trends in technology: the development of powered machinery for

production operations; the introduction of powered equipment to move materials and workpieces during the manufacturing process; and the perfecting of control systems to regulate production, handling, and distribution.

Devices to move materials from one work station to the next included conveyor-belt systems, monorail trolleys, and various pulley arrangements. The transfer machine, a *Transfer* landmark in progress toward full automation, moves the *machines* workpieces to the next work station and accurately positions them for the next machine tool. The first known transfer machine was built by an American firm, the Waltham Watch Company, in 1888; it fed parts to several lathes mounted on a single base. By the mid-20th century, transfer machines were widely employed in the automotive industry, appliance manufacturing, electrical-parts production, and many other metalworking industries, in which they cut labour costs and improved quality by ensuring uniformity and precision.

Automatic controls represented an innovation when applied to all aspects of the production process. The simple cam, automatically adjusting the position of a lever or machine element, was an important control device in many early machines and, during the 19th century, was used to make many machine tools automatic. But cam devices have severe limitations in movement, number of changes, speed, size, and sensitivity. True automatic control cannot be attained unless the machine is sensitive enough to adjust to unpredictably varying conditions. This requirement demands the technique known as feedback, which the microchip computer can perform in a fraction of a second.

Some students of automation maintain that its primary goals are not necessarily increased productivity or cost reduction but product reliability and quality control. Other benefits promised by automation include reduction of waste, improved plant safety, and centralization of control. Still, the most visible initial effects of automation have been reduction of costs and increases in productivity.

The industrial workplace. *Productivity.* Whereas the earlier phase of the Industrial Revolution had resulted in assembly lines mass-producing identical parts for mass markets, the introduction of the computer allowed for custom-made, small-batch production. For example, in the United States the chief investment in plants and equipment in the 1980s went into information technology, such as computers and telecommunications equip-*Niche* ment. Such aids have allowed American manufacturers to *production* concentrate on "niche" production—that is, supplying a limited segment of the market with a specialized product and responding speedily to changes in market demand. On the automobile assembly line, niche production enables many cars containing different options demanded by buyers to go down the same assembly line, with the computer making certain that the proper items go into each separate car.

These potentialities of automation have created two new fields: computer-aided design (CAD) and computer-aided manufacturing (CAM), often linked as co-disciplines under the title CAD/CAM. In a sense, CAD/CAM allows the mass production system to manufacture customized, "handmade" articles. The machinery can be adapted to a particular product through computer programming, enabling work on small batches to achieve many of the economies previously available only through mass production of identical objects. Computer-aided design itself makes possible the testing of production methods and the design of the product by running tests (of such factors as ability to withstand stress, for example) through the computer. If necessary, the product design or the process can be modified without going to the expense and time required for building actual prototype models.

Automation not only gives flexibility to production, but it also can cut down costly lead times in changing from one production model to another, and it can control inventories to provide a continuous flow of materials without expensive storage requirements or investment in spare parts. Such efficiencies lower production costs and help explain the growing strength in world markets of the Japanese, who first introduced the practice. Automation has also fos-

tered the development of systems engineering, operations research, and linear programming.

Automation has not yet realized the dream of completely robotized production. The first generation of industrial robots could perform only simple tasks, like welding, for they became confused by slight irregularities or differences in the objects on which they worked. To overcome that difficulty, computer scientists and engineers began developing robots with keener sensitivity, thereby enlarging their capabilities. Although progress has been made, it is clear that human beings must be available to back up the robots and maintain their productivity.

When automation was first introduced, each of the robots involved in complicated processes was controlled by a microcomputer programmed to perform only one task. As these processors could not communicate with one another and lacked memory, it was hard to trace which particular processor was responsible when something went awry. In the late 1980s this deficiency was corrected by the introduction of general-purpose computers, which bring together data from all the microprocessing units and make them accessible on one screen. This sped up the detection of problems and reduced the downtime of machinery, thereby increasing productivity and lowering expenses.

Effect on skilled labour. Robotic machines can perform certain unpleasant and dangerous jobs, such as welding and painting, that can be injurious to a worker's health. They can handle loads of up to a ton or more and work efficiently in temperatures ranging from near freezing to uncomfortably hot. Automation has eliminated much of the worker's physical and mental drudgery and has allowed the *Reduction* worker to change from a machine operator to a machine *of drudgery* supervisor.

At the same time, by increasing productivity as measured in output per man-hour, automation can reduce the number of workers. In the 1950s and '60s employment declined in the chemical, steel, meat-packing, and other industries in developed countries that achieved large increases in output. Except in certain older industrial areas in Britain and the United States, however, the widely feared onset of mass unemployment did not materialize. Although certain jobs and skills have been rendered obsolete, a vast array of new jobs calling for different skills has grown up.

Automation has brought about changes in the worker's relation to the job. Here the differences between labour practices in different countries prove instructive. The old management principle that work should be broken down into the smallest operations, so that the worker would not have to use any intelligence in performing a job, was based perhaps upon the notion that the worker is stupid. Hence, when full mechanization was introduced into American factories, the workers were not permitted to stop the moving assembly line if anything went amiss; that was presumed to be the task of supervisory engineering personnel. The result was both low productivity and a loss in quality control. In Japanese factories, on the other hand, assembly-line workers were allowed to stop the process when something went wrong. Indeed, the Japanese companies formed "quality circles," wherein the workers were given a say in the performance of their tasks and in the process of problem solving—an application of Mayo's Hawthorne effect, which they had learned from American management consultants. These practices improved both productivity and quality.

A similar way of enhancing quality and work performance is what is known as group assembly, which started in Swedish automobile plants and was also adopted by the Japanese and then by the Americans. With this system a group of workers is responsible for the entire product, rather than individual workers doing only one small task. If something goes wrong on an assembly line, an individual worker can push a button and hold things in place until the problem is resolved. This approach to production is being increasingly employed throughout the world. It already has had major implications for the labour force and labour–management relations. For one thing, it allows smaller numbers of more highly skilled workers, operating sophisticated computer-controlled equipment, to replace thousands of unskilled workers in assembly-line plants.

As a consequence, the highly skilled worker, who began to disappear with the introduction of the old-fashioned mass production assembly line, again became indispensable. The increasing use of automated machinery and control systems placed new demands on both the technical skills and the intellectual aptitudes of production workers. While automation may have eliminated many unskilled jobs, it increased the demand for highly skilled mechanical labourers and knowledgeable technicians who could operate the newer automated devices. As a result, the early prophecies that automation would reduce the need for workers' skills have proved to be false. Automation may be seen as improving efficiency and expanding production while relieving drudgery and increasing earnings—precisely the aims of Frederick W. Taylor at the turn of the 20th century.

Need for skilled labour

The office workplace. The introduction of computers also affected the organization of work in the information sector of the production economy. File clerks, bookkeepers, and other skilled office personnel involved in information processing were replaced by semiskilled keypunch and tabulating-machine operators. Office automation represents a further mechanization of office work, a process that began with the typewriter and the adding machine in the 19th century.

The information flow in offices has been likened to the movement of materials in manufacturing. Information, like materials, must be stored; typing or keypunching changes the form of the information, just as a machine operation changes the form of the workpiece; the value of the finished product is changed by adding information to it; and there must be a measure of quality control to make certain that the information is accurate. Just as automated machinery has done away with the jobs of many machine operators, integrated information-processing systems have eliminated many clerical tasks. For the production operation, automation provides an exact control over the inventory of raw materials, parts, and finished goods. Applied to billing operations in the office, it often can drastically reduce accounting costs.

The combination of computers and telecommunications led some to believe that office workers would perform their required functions without leaving their homes, as the computer terminal would take the place of their usual paperwork. Such predictions of "telecommuting" generally have not materialized, however. Social psychologists explain this by pointing out the social aspect of the work process, in the office as well as on the assembly line. Workers are, after all, social beings who benefit from interactions with their fellow employees.

The social aspect of work

Nevertheless, office automation affects management–worker relationships in a number of ways. It allows middle-level employees a means of providing company executives with reports of production, costs, and inventory. This removes the dependence on a few subordinates who had traditionally supplied such information. Automation also creates ways to monitor each office worker's efficiency: through computerized information managers can, for example, count the number of times per hour that a typist strikes a letter on the keyboard. Managers can also ascertain the number, times, and nature of a worker's telephone calls, monitor e-mail, or track the number and nature of Internet Web sites and employee accesses.

Women in the work force. For most of written history, agriculture was the chief human occupation, and heavy physical labour was not confined to men. Women performed backbreaking chores like grinding grain by hand in a stone quern, drawing and carrying water, gathering wood, and churning milk to make butter. About the only time women were given a respite was immediately before and after giving birth.

With the Industrial Revolution the work situation changed for both men and women. Whereas the hearth and home had formerly been the centre of production and family life, with industrialization the factory became the workplace and the town the dwelling place. The role of women in the family work force did not change overnight, however, for at first whole families were employed in factories almost as teams.

Family work teams

Not until the mid-19th century did the role of the male as the "good provider" emerge, with women relegated to household and domestic tasks. This was caused, perhaps, not so much by the change from farming to industrial technology as by a growing humanitarian protest against the harsh treatment of women and children in the early factory system. Legislation—most notably in Britain—raised the minimum age for child labour in factories, set limits on the working hours of women and children, and barred them from certain dangerous and heavy occupations. Thus, more women were engaged primarily in domestic tasks and child care at home while the men went out to work. Being the sole wage earner in the family reinforced the man's traditional position as the head of the family, who was expected to direct the lives of his dependents. Whatever authority the woman exercised derived from her status as mistress of the household.

The traditional role of the housewife (whose chief pursuits were motherhood and domesticity) persisted throughout the 19th century and well into the 20th. After the coming of electric power near the close of the 19th century, advances in technology brought labour-saving devices such as washing machines and vacuum cleaners into the home. Although they changed the nature of some tasks and freed the housewife from some drudgery, they did little to lessen the amount of time she spent on household duties.

Social and economic developments were the critical agents that changed the nature of women's work. For example, the growth of public education increased the demand for teachers, and growing industrial and commercial enterprises required more office workers and salespeople. Whereas men had previously performed teaching and clerical tasks, employers found they could hire women for these occupations—at lower salaries. Differences in pay between the sexes were based largely on the assumption that men had to be paid enough to support a family. On the other hand, most women who entered the work force in the United States before World War II were single and did not have families to support; hence, it was believed that they could be paid lower wages. This inequality in men's and women's pay scales, even for equal work, still exists.

Unequal pay for women

Technological changes affecting the maternal role of women also had an impact on their ability to leave the home. The development of contraceptive devices and the baby bottle and rubber nipple gave women greater freedom, making it easier for them to take outside jobs. Even if her employment was interrupted by childbirth, the woman could, within a relatively short time, reenter the work force.

Many working women performed tasks closely related to their traditional household work. When clothes were less often made at home but purchased ready-made at stores, for example, women were hired as seamstresses in the clothing industry. Even after national emergencies such as the world wars, during which women were encouraged to take manufacturing jobs to replace the men who were in military service, women returned to housekeeping or to traditionally female occupations such as office work and nursing.

In the 1970s married women began entering the labour force in great numbers, and the strict segregation of women into certain occupations began to lessen somewhat as new opportunities arose for female workers in traditionally male occupations. New technology has meant that many tasks that once required heavy physical exertion, and hence were restricted to men, can now be performed simply by pushing buttons. Operating a bulldozer, for instance, does not need muscle power so much as alertness, judgment, and coordination—qualities as plentiful in women as in men. Nevertheless, the entrance of women into occupations formerly the province of men proved to be slower than expected. This persistent occupational segregation by sex is largely responsible for sizable differences in rates of pay that still exist. It would appear that, although rapid technological progress has enabled women in highly industrialized nations to cast off certain traditional roles, technological determinism—or technological rationality—does not always prevail over cultural views and social practices inherited from the past.   (M.Kr./Ed.)

Delay in entering male occupations

INDUSTRIAL AND ORGANIZATIONAL RELATIONS

Industrial relations, or organizational relations, is a subject of study concerned with the behaviour of workers in organizations in which they earn their living. Scholars in this field attempt to explain variations in the conditions of work, the degree and nature of worker participation in decision making, the role of labour unions and other forms of worker representation, and the patterns of cooperation and conflict resolution that occur among workers and employers. These patterns of interaction are then related to the outputs of organizations. These outputs span the interests and goals of the parties to the employment relationship, ranging from workers' job satisfaction and economic security to the efficiency of the organization and its effects on the community and society.

Worker, manager, and society

CONCEPTIONS OF THE WORKER

19th- and 20th-century views. In classical economics, workers were treated like commodities, subject to the natural laws of supply and demand. Although classical economists readily acknowledged that workers are not motivated by money alone, they abstracted out of reality only the economic factors. This led them to consider workers as undifferentiated and passive instruments in the production process.

Karl Marx in the mid-1800s was the first to challenge this view of labour. He rejected the notion that workers should bear the costs of market forces and argued that all the value of production comes from workers' input; therefore, he insisted, labour should own the means of production. Since under a market system the means of production are owned and controlled by capitalists, workers would be exploited. Eventually, according to Marx and his followers, the injustice of this exploitation would lead to a revolutionary overthrow of the capitalist system and its replacement by a socialist system.

Later, around the turn of the century, two British political economists, Sidney and Beatrice Webb, joined this debate by arguing that a combination of worker and community forces would gradually achieve a socialist state. They shared with Marx a belief that workers and employers are separated by class interests and that only by organizing into trade unions would workers amass the bargaining power needed to improve their economic and social conditions. They did not believe, however, that a revolutionary overthrow of the capitalist system is necessary for social progress. Instead, through union representation, collective bargaining, and legislative protections, worker, employer, and community interests would eventually be harmonized.

About the same time the Webbs were developing their
American
institu-
tional
economists
views in Britain, an American view was taking shape under the work of John R. Commons and his associates at the University of Wisconsin. Unlike classical economists, these institutional economists believed that the laws of supply and demand can be influenced by the policies, values, structures, and processes used to govern employment relationships. Like Marx and the Webbs, Commons rejected the commodity view of labour and believed that an inherent conflict of interests separates workers and employers. He also believed, however, that these conflicts are a natural and legitimate part of any employment relationship and would not disappear if capitalism were replaced by socialism.

Consequently, these American scholars and social activists emphasized the importance of legislation that protects workers' interests in safety and health, unemployment and workers' compensation insurance, minimum wages, and retirement benefits. They also believed in the value of labour unions and in the need for negotiation and compromise between workers and employers. These institutional economists not only served as the forefathers of modern industrial relations, they also provided many of the ideas behind the labour legislation enacted as part of President Franklin D. Roosevelt's New Deal in the 1930s.

The advent of industrial relations. The New Deal paved the way for the development of modern industrial relations research and practice. In response to the economic and social crisis of the Great Depression, the U.S. Congress and the Roosevelt administration enacted a series of laws granting workers the right to organize into unions and to engage in collective bargaining with employers. Other New Deal legislation set minimum wages and provided a system of unemployment insurance and social security. In subsequent years unions organized large numbers of workers in the growing manufacturing, transportation, and communications industries. By the end of World War II nearly one-third of all American workers were union members.

After the war an exceptionally large number of strikes brought national attention to the problems of labour–management relations and led to the formation of a number of industrial relations research and teaching programs at leading American universities. The goal of these programs was to draw together the theories and insights of economists, labour and management specialists, and other social scientists to find ways to encourage greater cooperation and improved conflict resolution among workers and employers. Thus, the modern field of industrial relations was born.

Studies of worker behaviour. *Scientific management.* While Marx, the Webbs, and Commons focused on the role of labour in the late 1800s and early 1900s, others were developing theories of management. Frederick W. Taylor's engineering approach, later known as scientific management, was similar to that of the classical economists in regarding workers as passive instruments of production, but he did recognize differentiation among workers, at least insofar as degrees of skill were concerned. He developed methods for time-and-motion studies to determine the elements of particular jobs and the way in which these elements should be put together for the greatest efficiency. His focus was upon the individual worker; there was no place in his model for group membership or for the effects of groups upon individual behaviour.

Industrial psychology. A step further in the recognition of differentiation among workers came with the emergence of industrial psychologists, who are concerned with the measurement of the skills and aptitudes of individuals. At least in the early stages of these developments, workers were viewed as isolated individuals, and no attention was given to group phenomena.

Human relations. In the 1930s the emphasis of management researchers shifted from individuals to the work group. Of primary importance was the human relations research program carried out by Elton Mayo and his associates at the Hawthorne Western Electric plant and their discovery of the "Hawthorne effect"—an increase in worker productivity produced by the psychological stimulus of being singled out and made to feel important. The ideas that this team developed about the social dynamics of groups in the work setting had lasting influence.

Although the interpretations that Mayo and his group made of the test results have come under critical fire, the concern here is not with the validity of the conclusions but rather with the effects of the Hawthorne studies upon the subsequent development of management and organizational behaviour. Publication of some of Mayo's writings and of the major research report in *Management and the Worker,* by F.J. Roethlisberger and William J. Dickson in 1934, attracted large numbers of sociologists, social psychologists, and social anthropologists into a field that had previously been limited to economists, engineers, and industrial psychologists.

Four general conclusions were drawn from the Hawthorne studies:

1. The aptitudes of individuals (as measured by industrial psychologists) are imperfect predictors of job performance. Although such measures may give some indication of the physical and mental potential of the individual, the amount produced is strongly influenced by social factors.

2. Informal organization affects productivity. Although previous students of industry had looked upon workers either as isolated individuals or as an undifferentiated mass organized according to the formal chart of hierarchical positions and responsibilities established by management, the Hawthorne researchers discovered a group life among the workers. The studies also showed that the relations that supervisors develop with workers tend to influence the manner in which the workers carry out—or fail to carry out—directives.

3. Work-group norms affect productivity. The Hawthorne researchers were not the first to recognize that work groups tend to arrive at norms of what is "a fair day's work," restricting their production below that point even when they are physically able to exceed the norm and would be financially rewarded for it. However, the Hawthorne study provided the best systematic description and interpretation of this phenomenon.

4. The workplace as a social system. The Hawthorne researchers came to view the workplace as a social system made up of interdependent parts.

Behavioral science. Behavioral scientists had made their entry into the field by attacking the then-prevailing oversimplified notions of the individualistic economic person and the formalistic engineering notions of organizational structure, technology, and efficiency. As often happens in arguments between members of competing schools of thought, the force of the behavioral science attack carried some of its proponents so far as to view the work organization as simply a system of social relations and to downplay the role of economic forces. During the 1950s and '60s the field underwent a major process of redefinition, which consequently affected conceptions of the worker.

Behavioral scientists now recognize the importance of economic factors, but they see material rewards as having an effect upon behaviour in combination with social and psychological factors, and they study the pattern in this combination. Thus, over the years behavioral scientists have deepened the understanding of the role played by interpersonal, structural, and technological forces in organizations and industrial relations.

CONCEPTIONS OF THE MANAGER

Classical economists made no distinction between the manager and the entrepreneur, the person who brings together land, labour, and capital and puts them to work. This distinction did not take hold in the literature until the appearance in 1933 of the classic study by Adolf Berle and Gardiner Means, *The Modern Corporation and Private Property.* When the authors demonstrated that in most American corporations the owners (that is, the stockholders) played no direct role in the management of the concern and that the managers generally had insignificant holdings of stock, it became apparent that theories of entrepreneurial behaviour had little to contribute to the understanding of the behaviour of managers.

Specialized management. Somewhat earlier Max Weber, a German economist and sociologist, had approached the study of managerial behaviour through his concept of bureaucracy. To Weber the term bureaucracy did not have the negative connotation often heard in casual conversations. He used the term simply to point to a phenomenon of growing importance even in his time: the large organization with fixed positions linked together in a hierarchical pyramid, with specialization and division of labour, and with established rules and regulations governing behaviour. To Weber the manager was the individual who interpreted and applied the rules of the organization.

Later organizational sociologists, though recognizing the importance of Weber's contribution in focusing attention on the impersonality and rationality of modern industrial and governmental organizations, pointed out that Weber's model failed to take into account some of the most important features of the modern business organization. They argued that it gave an unduly rigid picture of organizations, that it failed to devote attention to processes of change, and that it built so exclusively on the hierarchy of authority as to neglect relations not explicitly defined by the structure. In any case, Weber's formulations were of interest primarily to social scientists. Practicing managers and students in business schools at that time were likely to have little familiarity with the Weberian approach to managerial behaviour.

The early model of the manager taught in American business schools applied these formal structural concepts by emphasizing functional specializations. In these terms the manager was the one who had mastered such subjects as accounting, marketing, production, finance, and so on. Later it was recognized by theoreticians and practicing managers alike that management was a good deal more than the sum of these specialized functions, and this realization in turn led to the conception of the manager as generalist, who would understand the various specialized functions and the people engaged in them. The emphasis turned to decision making, leadership, and the relation of the firm to its environment.

Participative management. In 1960 Douglas McGregor of the Massachusetts Institute of Technology published *The Human Side of Enterprise,* a classic book that had a major impact on subsequent management education and practice. McGregor challenged many of the prevailing managerial assumptions about worker motivation and behaviour. According to the prevailing view, which he labeled "Theory X," workers were viewed as uninformed, lazy, and untrustworthy members of the organization. Management's task was to control workers and motivate them through a combination of control systems, fear of discipline or dismissal, and organizational rules. McGregor contrasted this with a "Theory Y" assumption, namely, that workers are highly motivated and can be trusted to contribute to the organization's objectives if given the opportunity to participate in organizational decision making. Out of the work of McGregor and others, such as Rensis Likert, has evolved "participative management," a process in which managers consult with and involve subordinates in organizational problem solving and decision making.

McGregor's views were supplemented by theories that argued for the importance of integrating considerations of workers and their social environment into the design and implementation of new technologies and production systems. These sociotechnical concepts originated in Europe and had substantial impacts on the design of innovative work systems in Scandinavia in the 1960s and '70s. By the early 1980s they had achieved significant acceptance and use in American firms.

Sociotechnical and worker-participation models of decision making have grown in importance and popularity in response to the rise of global competition and the rapid pace of technological change. Most contemporary organizational and industrial relations scholars have concluded that the full potential of new information and manufacturing technologies can only be realized through management processes that support participation and communication across functional lines and departments, flexibility in how work is organized, and effective problem solving. Yet there is still considerable debate among practitioners over the feasibility or wisdom of involving workers in organizational decision making. Therefore, vestiges of both Theory X and Theory Y concepts and practices can be found in organizations today.

RESPONSIBILITY TO SOCIETY

The debate over the appropriate role for workers in organizational decision making is part of a larger debate over the extent of the firm's responsibilities to its community and society. This debate has been going on since the days of the Industrial Revolution.

The Industrial Revolution brought about great accumulations of wealth and also focused public attention on the apparent negative effects of rapid industrialization on working people. To what extent workers in the new factories were worse off than they had been in the much smaller-scale cottage industries may be a matter of continuing debate, but there is no question that large concentrations of workers—men, women, and children—crowded together in oppressive physical conditions and working long hours for low pay made the problem much more publicly visible. In the earlier period workers had dealt with owners

(margin note: McGregor's Theory Y)

and agents of whom they had some personal knowledge. The establishment of large factories destroyed that direct relationship, and it became less credible for the owner to claim that he took a personal interest in his workers.

Two models of social responsibility. In the past two centuries managers of industry have taken, in general, two broadly different positions regarding management's social responsibilities:

Laissez-faire. The first stance represents a sort of combination of laissez-faire economic theory and the Protestant ethic. In this view the owner or manager has no responsibility for the welfare of the workers outside the immediate plant situation; a person's station in life is a reflection of his intrinsic merit in the eyes of God; the wages and other labour costs incurred by the firm are the result of competitive market conditions. In this view, then, the owner's or manager's responsibility to his employees begins and ends with operating the firm in such an efficient manner that it is able to meet competition in the marketplace, and, if all business managers similarly followed a policy of intelligent self-interest, the broad social interests of society would be better served than by any other policy.

The expression of this point of view has undergone changes in style over the years. Today one hardly expects business leaders to state the position with religious overtones, and even the executive most inclined toward a laissez-faire viewpoint is likely to concede that there are some social problems that are not resolved by private initiative in pursuit of enlightened self-interest. However, managers with this view of the world tend to take a defensive position regarding the responsibilities of their firm beyond the gates of the plant. They recognize that popular opinion and government policies and programs may require them to take on activities not dictated by immediate material interest, but the tendency is to do what has to be done to keep out of trouble with the outside world and nothing more.

Paternalism. The other stance begins with the assumption that management has a social responsibility to the communities in which its plants are located. If one states the situation in this general way, hardly a management spokesperson today would deny this social responsibility. Yet, when one gets beyond rhetoric, one finds a wide variety of views as to what actions—if any—management should take. In assessing the present scene, one might do well to examine the historical evolution of conceptions of management's social responsibilities.

In the early part of the 19th century, the industrialist and social reformer Robert Owen was the first manufacturer to back up words about management's social responsibilities with a program of action. Having risen out of the work force in a textile mill himself, he was concerned with the social and economic conditions of workers and believed that the economic success of an enterprise did not have to depend upon exploitation of labour. In the mill town of New Lanark, Scot., Owen built workers' housing, schools, and a store that were far superior to contemporary standards for workers' communities. His philosophy was influential in the development of the cooperative movement in England.

Owen's ideas and the successful operation of his plant and community during his lifetime impressed many social reformers and the business community as well. His influence was clearly visible in the establishment of the industrial city of Lowell, Mass. Francis Cabot Lowell had made a trip to England and Scotland to study textile mills and related community problems before launching his own enterprises in Massachusetts. He had found New Lanark far more in harmony with American ideals regarding the dignity of the individual than was the average English industrial plant of the time. Lowell faced a social problem of an immediate practical nature: he had to recruit a labour force, largely female, not available in the towns where he was building his plants. To meet this need, the firm built, in what came to be the city of Lowell, a number of boardinghouses especially for young women. Each house was under the control of a woman who was supposed to ensure the morality of her charges,

and the young women were not allowed out of the house after 10 PM except with special permission. In addition, Lowell made liberal provisions for the building of schools and churches. He and his associates also gave stimulus to the Middlesex Mechanics Association, which sponsored cultural and educational programs.

Later in the century George M. Pullman undertook to build around his Pullman Palace Car Company a complete community (the town of Pullman, now part of Chicago) that would house all the employees and provide for all the essential facilities. In the early period of the Pullman Company, the quality of worker housing was notably superior to that of most other industrial workers.

When Henry Ford startled the industrial world with his announcement of the $5-a-day wage in 1914, he followed it with steps designed to help workers make good use of their increasing affluence. The company already had a small legal department set up to help workers with the complicated problem of home buying, and then Ford established what he called a sociology department. It was staffed with social workers who made home visits to workers' families to provide advice and help on family problems. Members of the department were also free to talk with workers within the plant during working hours in efforts to straighten out family problems.

How does one assess the success of such paternalistic efforts? In the United States the Lowell project was the longest lived and the most admired by foreign visitors. Charles Dickens compared Lowell very favourably with the typical English industrial city. Nevertheless, the distinctive character of Lowell had been lost before the end of the 19th century. Native New Englanders were replaced in the work force by the new immigrants and their children, and the women of these immigrant families had no rural homes to return to after several years of labour in Lowell, as had the New England girls. The boardinghouses thus lost their primary rationale, and by 1900 all of them had been sold by the companies. Even in the early years of the Lowell textile industry, conditions could not have been quite so idyllic as described by some of the visitors, for there were nine recorded strikes or lockouts in the mills in the period 1834–79.

The strikes greatly increased in frequency after this period, when management was faced with changes in social composition of the work force brought about by successive waves of immigration. One of the most famous of these was the "Bread and Roses" strike in 1912 of women textile workers in Lawrence, Mass. It got its name from the banner carried by some of the striking women indicating that they wanted both respect and improved working conditions as well as higher pay. It would seem to be more than coincidental that some of the most bitter strikes in the United States—from Pullman in 1894, through the Southern mill towns in the 1930s, to Kohler, Wis., in the 1950s— have taken place in company towns. (In fact, the Kohler strike holds the record as the longest strike in American history, lasting from 1954 to 1965.) Whatever economic grievances workers have had in these situations, it is clear that economic exploitation is not a complete explanation of the bitterness of the disputes. Whether benevolent or oppressive, the manager in the company town has far more extensive control over the lives of the workers than is found in other towns and cities. In the company town the owner or his agents not only run the plant; they also run the government, provide the local services, run the hospital, and so on. Any grievance a resident of the town may have is seen to be the fault of the company. When clashes in labour relations do arise in these situations, they are thus likely to look more like a struggle for independence than a standard union–management dispute.

The rise of unions in the mass production industries of the United States in the 1930s helped to persuade executives that a paternalistic approach to labour and community relations was no longer feasible. Extensions of management's social responsibilities were now achieved through collective bargaining. Still, these broader benefits, such as pensions and health insurance, were limited to the workers and their immediate families. There was a tendency to assume that any responsibility for the wel-

fare of the community as a whole should be assumed by government.

Modern objects of social concern. Although management's withdrawal from paternalistic community responsibility was accelerated by the growth of unionization, company officials began increasingly to see the need for the company to take part in the affairs of the communities where its plants were located. As the plants became part of large corporate organizations with headquarters in distant cities, company executives found themselves increasingly estranged from the local people. A common reaction to this estrangement was the development of public relations and community service programs. The plant manager's role was redefined to include the function of representing the company in the community, and this meant participating in community activities along with locally based business and professional persons. Thus, it became common to find the manager and other plant executives playing prominent roles in community fund drives and other service programs. Such activities, however, involved simply a commitment to maintaining the community rather than any initiative toward changing it.

In the 1960s managers began to recognize that the community service orientation was not adequate for coping with the problems of cities that were erupting in violence. By this period the leaders of the powerful unions that were negotiating with the leading companies had come themselves to be part of the new industrial elite. No longer were the unions seen as leading a broad movement for social change and a possible radical reordering of society. They came increasingly to be viewed as organizations devoted to the defense and improvement of status of workers who held a relatively privileged position in society compared with the "underclass" of workers who were employed in low-wage situations, who worked only sporadically, or who were unemployed. It became evident that the acute and chronic problems affecting society as a whole and industry in particular were not going to be solved simply by having a "good" management relating to its union and indulging in "good" relations with the communities.

Plant closings. Debates over a firm's responsibilities to the communities in which its establishments are located intensified in light of the increased number of plant closings and corporate restructurings that occurred in the United States in the 1980s. Many of these closings resulted from intensified international and domestic competition; others were caused by technological changes; and still others reflected shifting corporate business strategies and priorities. Regardless of the cause, community leaders argued that employers should provide their workers and communities advance notice and should work with employee and community leaders either to avoid the closing and job loss or to ease the process of worker and community adjustment. These pressures were voiced most strongly by leaders in the older industrialized cities of the Midwest and Northeast that were hardest hit by the migration of manufacturing jobs to the South and to countries with a lower wage scale.

Many companies responded to these calls by providing advance notice voluntarily or through collective bargaining and by working cooperatively with community and union representatives to ease the transition. In a small number of cases workers and unions took the initiative by purchasing businesses and transferring them into employee-owned enterprises. The record of this latter strategy is at best mixed. Some of these plants survived and thereby continued to provide jobs, albeit often at reduced wages and pension benefits. Others, however, failed for the same reasons that prompted the original owner to want to abandon or move the business.

Concern over this issue led nearly all industrialized countries to enact legislation requiring companies to notify workers and communities of impending plant closings or mass layoffs.

Demographic changes. Over the years employers have had to broaden the scope of their responsibilities in answer to changes in the demographic makeup of the labour force and to various social issues that affect the employment relationship. For example, in the 1960s the United States enacted a series of equal employment opportunity laws, which forbid discrimination in employment on the basis of race, colour, creed, sex, age, or handicapped status. Companies that do business with the federal government have an additional obligation to demonstrate that they have taken affirmative action to provide job opportunities for women and minorities.

Since the 1960s, therefore, firms have carefully reexamined and upgraded their recruitment, selection, training, and promotion policies to eliminate discriminatory practices. The evidence on the job market status of blacks and women shows that, while these legislative and company-level initiatives have helped to reduce the income and employment differentials of blacks and women, sizable gaps in wages and occupational status still remain. Moreover, while most employers have eliminated overt forms of discrimination from their formal personnel policies, many observers believe that there is still considerable subtle discrimination that holds back women and minorities in organizations. Research has shown, for example, that some managers tend to systematically bias their performance evaluations of women or minorities. Others unconsciously hold lower expectations for women or minorities or are uncomfortable in dealing with them as equals or superiors.

Because of their subtle nature these forms of discrimination are especially hard to eliminate from organizational life. New practices such as the use of mentors (senior managers who look out for and provide career advice for junior employees), ombudsmen (third-party neutrals who help to solve conflicts and resolve problems in organizations), and peer support groups or networks are now being used in leading firms to address the remaining discriminatory practices that hold back the full utilization of all members of the work force.

Stakeholder versus stockholder. Debates over the scope of corporate responsibilities have raised an important theoretical question that goes to the heart of the purposes and roles of the modern corporation. Is the corporation's only, or primary, responsibility simply to maximize the value of its shareholders' investment? Or is it more appropriate to recognize that the modern corporation has a responsibility to serve the interests of multiple stakeholders, including not only its stockholders but also its employees, communities, customers, suppliers, and the broader society in which it is located?

This question takes on added importance in a world where capital is more mobile, corporate takeovers have increased in number and frequency, and multinational corporations may have, by definition, multiple national allegiances. A stakeholder model would argue for development of new forms of corporate governance where these multiple interests are represented in organizational decision making. Workers might, for example, be represented on corporate boards of directors, as they are in many European countries and in a small number of American firms where employees either own substantial stock in the corporation or have taken significant wage concessions to save the company and their jobs.

American managers are often criticized for their failure to adopt a long-run view of the corporation's objectives, following instead the strong tendency built into financial markets and institutions to maximize short-run profits. The adoption of a stakeholder view of the corporation's responsibility would challenge this tendency. The evidence most often cited for this belief comes from comparisons between the behaviour of American and Japanese firms. Japanese executives appear to take a longer and broader view of corporate objectives than do their American counterparts. One reason (but not the only one) for this is that the cost of capital is lower in Japan than in the United States. Therefore, Japanese firms can achieve more favourable economic returns for long-term investments than can comparable American companies. This allows Japanese executives to invest in new products and processes that will build and protect a stable employment base and allow the firm to grow over the long run, even though short-term profits may be sacrificed.

A stockholder wealth-maximizing model would argue for a more laissez-faire, or free market, approach by limiting government regulations and worker or community repre-

views

sentation in corporate decision making. While the long-run trend has been to broaden gradually the scope of the corporation's responsibilities to its communities and work force, corporate law still treats the maximization of shareholder wealth as the primary responsibility of firms and their top executives and directors.

The changing work force

In the past when one wanted to describe the demographic and social characteristics of the work force and the career patterns of its members, it was common to divide individuals into two categories: managers, or "salaried" employees, and workers, or "hourly" employees. The laws governing employment practices still make this distinction, as salaried employees are "exempt" from much of the wage-and-hour legislation that governs the rights of "nonexempt" hourly employees. The increasing diversity, however, in both the characteristics of the labour force and the organization of work make these categories less helpful.

Consider, for example, the following projections issued in 1987. by the U.S. Bureau of Labor Statistics for the future up to the year 2000. Over 85 percent of all new entrants to the work force will not be white males. Instead they will be women, minority group members, and immigrants. A majority (55 percent) will be women. At the same time, most of the new jobs will be created not in the large manufacturing firms once thought of as the typical place of employment but in the service sector. In addition, the majority of these new jobs will be created by small rather than large firms. Furthermore, the educational requirements of the "typical" job are expected to continue to increase.

Taken together, these trends worry many industrial relations and personnel experts and managers. The fear is that there may be a mismatch developing between the characteristics of future labour force entrants and the types of jobs that will be in high demand. If this is true, considerable efforts will be required to improve the match between supply and demand. This in turn implies that individuals will need to engage in a lifelong learning, training, and retraining process and that firms will need to increase their investment in training. The changing nature of the labour force further implies that employers will experience intensified pressure to open up opportunities for advancement to women, minorities, and immigrants.

INTERESTS, VALUES, AND EXPECTATIONS

The interests, values, and expectations that workers bring to the workplace provide a useful point of departure for understanding how employees respond to managerial policies. While these psychological features vary among individuals, over time as workers move through different stages of their family and career cycle, and across nationalities, they do reveal certain similarities.

Assessing workers' interests.   There is a long-standing debate between psychologists and economists over how best to ascertain worker interests and expectations. Psychologists have traditionally used survey questionnaires and interviews to measure worker attitudes, values, and beliefs and then examined the relationships of these attitudes to observable workplace behaviours such as job search, turnover, absenteeism, union organizing, and withdrawal from the labour force. The value of this approach is that it provides a direct measure of an individual worker's expressed attitudes and beliefs. Economists favour direct observation and measurement of these observable behaviours. This provides evidence of what economists call "revealed preferences," preferences that are revealed by actions taken. Both approaches are helpful in painting a complete picture of workers' views and the workplace outcomes that result from these views.

Since work is the most important source of income, it is no surprise to find that all workers place a high value on the income and security provided by their jobs. Both survey evidence and labour market behaviour demonstrate that workers expect their jobs to provide both adequate and fair compensation. Fairness, or equity, is normally assessed by comparing one's wages and fringe benefits with those of others in the same occupation, area, industry, or organization. Failure to provide adequate and equitable wages has consistently been shown to lower workers' job satisfaction and to increase the likelihood that workers will prefer either to look for another job or to act on the job to increase wages through organizing a union or striking. Furthermore, there is no evidence that the expectation of high and equitable wages weakens as individuals move up the occupational ladder and receive higher pay. Even among professionals, pay dissatisfaction continues to be a strong predictor of job turnover. **Adequate and fair wages**

Most workers expect much more from their jobs than high and fair pay. In fact, perhaps the most important long-run trend in worker values is the gradual expansion and broadening of worker expectations. Survey data have shown that the vast majority of workers not only in the United States but all over the industrialized world place a high value on autonomy, opportunity for advancement, and the ability to have a say in how they do their work. Moreover, the higher the level of education, the higher the value workers tend to place on these aspects of their jobs. Given that educational attainment levels are gradually rising, these dimensions of employment are becoming more central to behaviour at the workplace. It is not surprising, therefore, that leading employers throughout the world have been experimenting with innovations in the organization and management of the workplace that provide workers with these satisfactions.

Voicing workers' interests.   With broader expectations and higher levels of education also comes a more assertive work force—one that is able and willing to voice as individuals or groups their demands or expectations. The means chosen to exercise voice at the workplace vary with the legal status and availability of collective forms of representation, degree of employer resistance to unions, and workers' preferences for individual or collective action.

There is a widely shared belief that workers' rights to challenge or seek changes in employer policies either as individuals or collectively should be protected by government policy and respected by employers. Even in the United States, for example, where the tradition of individualism is stronger than that of most other national cultures, surveys consistently show that more than 80 percent of the population believe workers should have the right to join unions or employee associations designed to give them a voice in shaping their employment conditions. While this right is provided by law in all industrialized democracies around the world, this is not always the case in developing nations or in totalitarian states.

Individual and collective action.   Despite this widely shared belief in the right of workers to form unions or engage in collective bargaining, there are wide variations in the means workers prefer to use to assert their interests at the workplace. Generally, the higher the education and occupational status, the more workers prefer to assert their interests individually. Or, when organized, higher-level professionals such as teachers, doctors, lawyers, engineers, scientists, and middle managers tend to act collectively through occupational associations rather than in broad-based unions with blue-collar workers. **Professional workers**

This occupational or professional approach helps to create and reinforce the professional ties and status of these groups as well as to bring their special needs to the attention of employers. Moreover, these groups tend to rely on the power they derive from their labour market and geographic mobility along with professional norms, licensing or certification procedures, and government-passed standards as much as, if not more than, they rely on collective bargaining. Still, in some countries of Europe an increasing number of white-collar and professional employees are organized into unions and negotiate collectively with their employers.

Blue-collar workers who have highly marketable skills also derive individual bargaining power from their potential mobility. Blue-collar workers around the world, however, are also more likely to form unions and bargain collectively to promote and protect their interests. In turn, while most employers would prefer to not have

their employees join or form unions, in the vast majority of industrialized democracies employers have respected workers' rights to organize.

Perhaps the strongest employer opposition has been found in the United States. American labour history is replete with pitched and often violent battles between workers seeking to organize and employers seeking either to avoid or eliminate unions. Even after the violence associated with these historic battles abated, both survey data and employers' revealed preferences continued to show that American employers placed a high priority on discouraging their employees from unionizing. The current and future status of unions and other forms of worker representation continue to be one of the most controversial issues in American industrial relations.

Participative decision making. How strongly do workers wish to take part in decisions that affect them? Do they want to be coequals with management on issues, or are their interests more limited? Such questions have been at the centre of many historic debates among industrial relations scholars, practicing managers, union leaders, and public policymakers. The evidence is surprisingly robust over time and across national boundaries: workers reveal the greatest interest in participating in decisions that affect their immediate economic concerns and those that directly affect their specific job.

Survey data collected from workers across 12 European and North American countries show that the majority of employees want a say in workplace decisions such as how they are to perform their jobs, how jobs are organized, and how problems related to their immediate environment are solved. An equally strong majority want a say on bread-and-butter economic issues such as wages, benefits, and safety and health conditions. Only a minority favour direct participation or indirect representation in the broad strategic business decisions normally made by high-level executives or the boards of directors of a firm. The one strategic issue that workers demonstrate real interest in influencing, however, is the role of new technologies at the workplace. When they can see a link between strategic managerial decisions and their own long-term economic and career interests, workers want to have a voice in those decisions.

Given these broadly shared values and expectations, some of the particular work and career concerns of various occupational and demographic groups are examined below.

WORK CAREERS

Managers. In all industrialized countries managers are typically recruited from among university or postsecondary technical-school graduates. Although there are exceptions to this pattern, it is becoming rare for blue-collar workers without a college or technical-school degree to rise beyond the level of first-line supervision into the ranks of higher management. Yet because few graduates fresh out of a university or technical school have the experience or background necessary to assume broad-based or high-level managerial responsibilities, most organizations invest heavily in systematic management training and development efforts.

Training and promotion. An initial part of the training often involves socialization into the practices, values, and culture of the organization. Another source of training and development lies in the career paths and job rotation policies of the firm. One large multinational firm, for example, devised a 10-year management development plan for all its junior managers, assuming that within those 10 years the manager would change jobs at least five times. Each job change was expected to expose the junior manager to a different functional area, such as marketing, finance, technology or product development, and manufacturing. Each job change also was expected to increase the number of people the manager supervised or the level of responsibility. This firm, like an increasing number of others, attempted to include international experience in the career path, especially for those young managers targeted early in their careers as having the potential to rise to the level of senior management.

Many firms make an explicit judgment of this potential early in a manager's career and put those thought to have the most potential onto a "fast track" developmental path. In smaller professional organizations, such as law offices or consulting firms, a similar decision is made within the first five to seven years on whether to promote an individual to the status of partner in the firm. This "up or out" decision is analogous to promotion to tenure of faculty members in most universities at some point prior to the seventh year of service.

Researchers have shown that managerial career patterns can be predicted quite accurately by the results of these early promotional outcomes. Some have used the analogy of a tournament to describe the process, in which "losing" at any step along the way significantly reduces one's chance of "winning"—that is, getting to the top of an organization or profession. Thus, a failure to get a promotion one expects (or that others expect a manager to get) often is a signal for the manager to look for opportunities in another organization.

Competitive pressures. The competitive career environment described above can lead to considerable tension and stress among middle managers. This stress is intensified by the desire of many firms to reduce the number of levels in the management hierarchy and the number of middle managers.

Rapid changes in business practices and knowledge also create a strong demand for continuing education programs for middle and senior managers. Most leading business schools and numerous consulting firms offer various short refresher courses or short conferences to practicing managers. Firms spend a significant amount of their training and management development resources on such programs.

In large companies that have plants or offices in many different locations, moving up the managerial hierarchy usually requires a number of geographic moves. While employers normally give a manager the option to accept or reject a geographic transfer and promotion, individuals who want to rise in their organizations tend to be reluctant to reject such offers. Yet the process of selling a house and moving one's family to another community can be difficult, especially if both the husband and wife have careers or their children are in early adolescence. This tension between work and the responsibilities and priorities of family life is a growing concern in many leading companies, especially as the number of women managers and dual-career couples increases.

Blue-collar workers. *Career structure.* The career of blue-collar workers can be divided into four parts: initial education and entry-level training period, trial or job-matching period, stable period, and retirement.

The long-run income prospects of a blue-collar worker are heavily dependent on the amount and quality of basic education. Failure to complete high school reduces significantly one's expected lifetime earnings. Obtaining post-high-school technical training through vocational schools, community colleges, or apprenticeship programs that involve both formal schooling and on-the-job experience increases expected long-run earnings. Finally, choosing a job that provides additional training opportunities either on the job or through part-time outside course work further increases a worker's earnings potential.

Thus, the initial career stage is one in which an individual is investing in education or, as social scientists put it, building human capital. Failure to complete high school or to acquire basic mathematical, verbal, and analytical skills not only limits long-run earnings but also increases the risk of being unemployed for longer periods than those who invested more time and energy in this period of education and training.

Following the completion of schooling and entry-level training, most workers experience a trial period in which they change jobs a number of times in search of a good match between their abilities and aspirations and the opportunities available to them. The average worker changes jobs six to eight times before settling into a stable employment relationship. Because most firms follow a seniority rule in laying off workers (that is, the most junior workers are laid off first), some of this job movement may be

Margin notes:

The tournament analogy

Building human capital

involuntary. In searching for a job, blue-collar workers tend to rely heavily on informal contacts and information provided by friends, family members, or school advisers.

The most stable period of employment for this group of workers occurs between the ages of 30 and 60. As family responsibilities become greater and seniority increases the security of employment within an organization, the likelihood of staying with a given firm likewise increases. The potential costs of job loss also tend to mount over time, as it becomes harder to find a job with another company that will replace the wages and benefits often achieved after years of service and internal promotion.

Two different factors affect workers as they approach the retirement stage of their careers. The first is that, while age 65 still serves as a customary age for many to retire, firms are no longer allowed to impose a mandatory retirement age. Thus, theoretically, employees can continue working as long as they are able to do the job required of them. Few blue-collar workers, however, choose to stay on beyond age 65. Instead, an increasing number of them retire and then take part-time jobs. The second factor is the growth in early retirement among blue-collar workers, prompted in part by the early retirement incentives many firms offer to employees between the ages of 55 and 65. This also has led to a growing number of older workers employed part-time.

Interests at different career stages

Job, union, and community. Along with the stages in workers' careers go shifting attitudes toward their jobs. When workers remain with the same company, their outlook on the job and the company tends to follow a curvilinear pattern: high at first, then dropping through the middle period, and rising in the later parts of their career. Individuals tend to begin work with such unrealistically high expectations as to the nature of the jobs and the opportunities before them that disillusionment later sets in; but after some years they adjust themselves, lower their expectations, and express more satisfaction with the work situation.

Interest in joining a union or in becoming a leader in the union tends to follow a reverse curvilinear path. Interest is low at the beginning of tenure with a company because of the uncertainty over how long the worker will stay with the firm and because job satisfaction is generally high. Then, as job satisfaction declines over time and the worker recognizes that the costs of leaving the firm are rising as he or she accumulates seniority benefits and family obligations, interest in changing conditions in a given job or firm rises and stays fairly high. Only as retirement approaches and the costs of leaving the firm become untenable does job satisfaction again rise, thereby lowering the worker's tendency to participate in aggressive efforts to change the status quo.

A number of studies have shown that few blue-collar workers want to leave their community when the plant or office shuts down. It is clear that the availability of jobs at high levels of pay elsewhere is not in itself enough to move people. Ties with friends and family make workers reluctant to leave, but there can be good economic reasons as well. They may, for instance, find that housing costs are much higher in communities where job opportunities are expanding. Blue-collar workers and their families are therefore likely to conclude that it is best to stay where they are in the hope that the job market will pick up.

Service-sector workers. Most research on the careers and expectations of workers comes from blue- and white-collar workers employed in manufacturing industries. Yet this sector is shrinking in comparison with the service sector. In most advanced industrialized economies, more than half of private-sector workers are employed in services, compared with approximately 20 percent in manufacturing.

It is difficult to generalize on the nature of service-sector employment and careers, as they vary widely. For example, while average wages in service-sector jobs are lower than average wages in manufacturing, the wage differential between the best and the worst jobs in services is also larger than the comparable differential in manufacturing. This greater inequality of income (and skill requirements) helps explain why workers who are displaced from jobs in manufacturing experience, on average, significant pay cuts in the jobs they are able to find in the service sector. The best predictor of the size of the difference in pay between the job lost and the new job is the amount of education and transferable training the worker possesses. Again, education and training are critical to income and employment security and career advancement.

Service-sector jobs differ in several other important dimensions. First, more women are employed in services than in manufacturing. Second, services employ a relatively large and growing number of part-time workers, some who work part-time by choice and others who move to a full-time job when and if one is available. Third, low-paid service jobs tend to have high rates of turnover and lack many of the fringe benefits, training opportunities, seniority rules, and union protections found in the more stable and better-paying manufacturing, professional service, or public-sector jobs. Finally, service firms tend to be smaller in size and more vulnerable to changes in market or technological developments outside the control of their owners. For all of these reasons, the shift in the labour base from manufacturing to services has engendered vigorous debate over the ability of these new jobs to meet the high and ever-expanding expectations of the work force.

Technical professionals. The first research in industrial relations focused on blue-collar workers. Gradually attention spread to foremen and then to higher levels of management. Considerable attention has also been devoted to the study of scientists and engineers who work in industrial organizations. Interest in these technical professionals in part reflects the importance organizations attach to the development and use of new scientific discoveries and technologies. How well these technical professionals and the research and development processes they engage in are managed can have substantial effects on the long-run profitability of a firm and on the competitiveness of the larger economy.

Role in research and development

Scientists or engineers are often thought of as solitary individuals who work in a laboratory on some abstract problem or idea. While this may be an accurate image of the relatively small number of scientists who work on basic research, the vast majority of technical professionals in organizations actually work together in teams or project groups on applied research and development tasks. Their primary role is to transfer new scientific discoveries or ideas from the laboratory to manufacturing and out to the marketplace by creating new products or technologies. These project teams include representatives of diverse functional groups within the organization, including specialists in marketing, manufacturing, and human resource management as well as representatives of various scientific disciplines or technical specialties.

Interests and concerns. What do technical professionals want from their jobs and careers? Like all other workers, scientists and engineers are concerned about their employment security and long-term career opportunities. Concern over employment security arises in part from their dependence on winning contracts from customers or on obtaining budget funds from top management to support their project ideas. Because of the uncertainty over project funding, some firms try to keep their permanent research and development staffs rather small and hire engineers and other technicians as consultants on a contract-by-contract basis.

Like other professionals, scientists and engineers also want to gain the respect of peers in their field of work. Recognition of this desire led many early researchers to argue that these professionals were externally oriented—that is, they wanted to contribute to science and placed a relatively low priority on the needs of their particular employer. Later research showed, however, that most technical professionals also want to work on problems that are critical to the success of the firm. They want to know what the firm's priorities are and be given an opportunity to contribute to those goals. Above all else they want to be assigned to important and challenging projects and then be given the resources, influence, and autonomy needed to complete the projects successfully.

Career paths. Not all technical professionals want to

remain in technical jobs throughout their careers. Some aspire to move into management; others want to continue to do technical work but want the status and economic rewards that normally come with promotions to higher management. This has led many organizations to establish a dual-ladder progression system. Individuals in midcareer can seek promotions to more senior assignments on the technical ladder or to administrative positions on the management ladder. In theory the steps on each ladder are supposed to provide equivalent economic rewards, influence, and status. In practice, however, the management ladder usually provides broader exposure within the organization and thus better access to senior executive positions. Experience has shown that dual-ladder systems are extremely hard to administer.

Organized research and development. In the past, research and development work was organized in a serial fashion with a project passing from one group of specialists to another until it was ready to be given to the manufacturing section. The metaphor of "throwing it over the wall" was often used to describe this mode of organization, signifying both the serial and the isolated nature of each stage of the process. Research evidence convinced most organizations that this was very inefficient and time-consuming, and firms now encourage more cross-functional communication and participation by bringing together teams of representatives from each stage of the development process. The goal is to coordinate the process better and to identify and avoid problems that otherwise might be discovered only at a later stage.

To work effectively in these cross-functional project teams, scientists and engineers must have both up-to-date knowledge of their technical disciplines and skill in the communications, problem-solving, and group decision-making processes needed for successful teamwork. Universities are now placing more emphasis on the development of these skills in their curricula, and organizations are seeking ways to reinforce these attributes in the career development and reward systems.

One key to the success of the research and development process is the project leader, who must motivate, lead, and coordinate team members. At the same time, the leader must represent the group's interests in the larger organization by serving as a champion for the team's project and negotiating with management for the resources needed to get the job done. In the end, it is the project leader who is held accountable for keeping the project on schedule and within budget.

The project leader

Organizational design

A central task of management is to motivate individual workers and coordinate their collective efforts in ways that achieve the organization's goals. Over the years the concepts and methods used to structure work and to design organizations have changed considerably. In fact, it has been noted that an organization's age can often be predicted by the way work is structured, as work practices tend to reflect the organizational design theory in vogue at the time the organization was founded.

TWO MODELS OF WORK STRUCTURE

Specialization of function and separation of authority. Much of the organizational design in the United States can be traced to the influence of Frederick Taylor's scientific management movement and the division-of-labour concepts found in Max Weber's description of the ideal bureaucracy. One of the reasons for the durability of these concepts is that they helped make the modern corporation with its multiple divisions and functions both manageable and successful. Formal bureaucratic rules, specialization of functions, and close supervision proved suitable for disciplining and directing an immigrant and poorly educated labour force in factories geared to mass production markets. The phenomenal success of American manufacturing organizations in the first half of the 20th century reinforced managerial faith in these systems and provided workers with sufficient improvements in income and standard of living to support their continuity. Furthermore,

the American labour movement adapted well to these principles, and the collective bargaining system that grew out of the New Deal of the 1930s provided workers with the opportunity to have their voices heard, if only indirectly, through union representatives.

Scientific management was based on the principle of a clear separation of authority between the engineers and supervisors, who decided how to organize work, and the production employees, who carried out the boss's orders. Also, it emphasized narrow job definitions and clear divisions of labour between jobs, thereby accommodating the presumed lack of education or skills of production workers. Finally, scientific management emphasized individual incentive wages. Paying each worker for the output he or she produced was expected to maximize employee motivation and overcome any presumed conflict of interest between the worker and the firm.

When the industrial unions that grew rapidly after the 1930s inherited this form of work organization, they generally accepted it, but they codified job descriptions, negotiated wage rates for each job, and established principles of seniority to govern worker rights to different jobs and workplace benefits. All these provisions were written into a collective bargaining contract, and disputes over interpretation of the contract were resolved through grievance arbitration.

The tightly structured workplace

This workplace system was combined with an equally tightly structured and differentiated managerial and technical hierarchy and departmental or functional division of labour. Specialization of function and clear lines of authority separated managers assigned to such various departments as marketing, sales, finance, personnel, production, and engineering. Within the engineering and new-product development process similar specialized tasks separated design engineers, manufacturing engineers, industrial engineers, and so on. A large cadre of middle managers produced the accounting and other financial reports needed by top executives to monitor and control operations and to allocate resources for new initiatives.

In a growing domestic economy and expanding mass markets, these organizational design principles allowed American firms to use their economies of scale to improve productivity and reap large profits. Sharing the fruits of these economic returns with the labour force in turn produced a stable industrial relations system that provided the labour peace and predictability needed to take advantage of expanding market opportunities. By the late 1940s and early 1950s American managers, union leaders, and policymakers alike were generally convinced that the American industrial relations system was superior to any other. Therefore, after World War II, efforts were made to export American institutions and practices to the nation's war-torn allies, as well as to its former adversaries Germany and Japan and its Cold War adversaries in communist-bloc nations.

Participatory management and flexible work systems. By the 1960s many of these traditional principles of organization and work group design were being challenged by early advocates of participatory management. Arguments for enlarging the scope of responsibilities and influence of individual workers were presented as better means of motivating workers and increasing job satisfaction. While these ideas gained favour in a number of the new companies and high-technology industries that grew rapidly through the 1960s and '70s, it was not until the following decade that they began to gain support within existing organizations in the manufacturing and service sectors.

In the 1980s, when American firms faced significant productivity and quality performance problems, large numbers of American managers challenged traditional principles of organizational design. Also important was the recognition that Japanese and some European firms were outperforming American firms by using more flexible work systems and participatory management practices.

Challenges to American organizational design

The development and implementation of new microelectronic technologies in that decade reinforced the pressure to introduce flexibility into work organization and to break down many of the traditional dividing lines between jobs. A number of scholars argued that the full benefits

of these new technologies could be realized only when, as one of them put it, workers are given the training, motivation, and organizational influence needed to "give wisdom to the machines." By this is meant that worker input into decision making must be encouraged and valued and that workers, technicians, and managers must work together to solve problems and resolve conflicts that arise between workers and managers and across functional groups. At the same time, experience showed that maintaining high levels of trust, commitment to problem solving, and flexibility requires a corresponding commitment from the firm to give a high priority to employment security and related employee interests.

Managerial critics have argued that new technologies also provide the option to "de-skill" many clerical and blue-collar jobs and give management new methods for controlling workers and invading their privacy. For example, computers can be programmed to monitor the work of machine operators and therefore to serve as a new form of electronic surveillance that replaces the personal presence and control of the supervisor or production foreman. The introduction of new technologies also displaces—and in some cases replaces—labour, posing a threat to the job security and economic livelihood of the workers affected. Thus, a critical challenge facing managers, worker representatives, and public policymakers lies in the management of technological and organizational change in ways that benefit not only individual firms but also the work force and the larger society.

CHANGE IN ORGANIZATIONS

The important issue of organizational change has always been a central topic of interest to theorists of industrial relations and organizational behaviour. Early studies focused on a presumed resistance to change among employees. It soon became apparent, however, that much of the resistance could be overcome or avoided by involving those affected in the design and implementation of the change. But it was also discovered that the management of change is an ongoing and complex political process that requires considerable leadership and resources.

A widely acclaimed theoretical model of the change process was developed in the 1940s by social psychologist Kurt Lewin. He argued that successful organizational changes move through three stages, or cycles. The first stage involves the unfreezing of existing practices or behaviour patterns. This is most easily achieved if the organization is subject to some serious external threat or economic crisis. In the absence of a perceived crisis, employees are likely to see insufficient reason to change, and managers are often unwilling to commit the needed resources or to accept the risks that accompany change.

If practices or behaviours are successfully unfrozen, there is a period of experimentation, or trial and error, with new practices. Here the challenges are to implement changes in ways that respect and accommodate the interests and concerns of those affected and to demonstrate that the changes produce tangible improvements in organizational performance or employee well-being.

The final stage comes as a new set of practices is institutionalized and becomes the standard or accepted way of doing things.

Research has shown that each stage of change can take on the characteristics of an intense political process, in which those advocating the change must attract sufficient support from top management, union leaders, and rank-and-file workers to keep the process moving forward and to avoid the tendency of organizations to fall back into past patterns or practices. The job of a contemporary manager or union leader, therefore, has been described as a change agent. As the pace of technological and social change intensifies, the ability to manage organizational change and innovation successfully grows in importance.

Lewin's theory of the change process

Union–management relations

Of the variety of conflicts found in industrial organizations, those involving unions and management have received the most attention. Labour unions are the primary means workers have for advancing their collective interests at the workplace and in the broader society. Much of the history of industrial relations is filled with efforts on the part of workers to gain the right to organize into free trade unions—that is, worker organizations that are not controlled either by employers or by the government.

While the actual percentage of workers who are organized into unions varies considerably from country to country and over time within individual countries, it is safe to say that there is no democratic country in the world where independent trade unions are not present. Unions serve an essential role in a democratic society by giving independent voice to worker interests. The best evidence of the importance of this function is that unions are often among the first democratic institutions (along with the church and the press) attacked by totalitarian regimes.

Unions and union–management relations are also of special importance in that, through collective bargaining and other formal and informal means of interaction, unions and employers establish the wages, hours, and working conditions of large numbers of workers. In countries such as Sweden, Denmark, and Norway, collective bargaining covers more than 80 percent of the labour force. In Britain, Germany, and Japan it covers between one-third and two-thirds. Even in countries like France or the United States, where less than 20 percent of the workers are unionized, collective bargaining often sets new patterns in wages and other conditions of employment that are then adopted by nonunion employers as well.

It should be noted that employers are often reluctant participants in collective bargaining. While the degree of opposition to unions varies among countries, most employers would prefer not to deal with unions. This opposition is perhaps strongest in the United States, where employers have aggressively opposed unionization of their employees. This is one of the reasons why the right of employees to organize and bargain collectively is normally protected by law.

Employer opposition to unions

The 1980s and '90s were marked by tremendous pressure for change in union–management relations around the world. This pressure came from increases in market competition within and between countries, the rapid rate of technological progress, the changing nature of the work force, shifts in jobs from highly unionized large manufacturing firms and industries to smaller, newer firms and service industries, and, in some countries, the election of governments less supportive of unions. As a result unions in the majority of industrialized countries lost membership and started seeking ways to adjust their strategies and practices to their changing environments. The following discussion, therefore, focuses both on the traditional union–management practices that have dominated relations since the 1930s and on how these practices have responded to pressures for change.

UNION ORGANIZING

The typical way in which workers become organized into a union in the United States is through an election campaign and vote on representation. A majority of workers must vote in favour of union representation and collective bargaining. In these campaigns arguments about the need for a union and the benefits of collective bargaining are countered by employer efforts to convince workers that they do not need a union. American workers historically have taken a pragmatic approach to this choice: they vote in favour of union representation only when they are highly dissatisfied with their employer and when they see union representation as a viable means of improving their employment conditions.

In the case of clerical and professional employees, unions have argued that one need not see the employer as hostile or untrustworthy to believe in the need for collective representation. When an organizing drive took place among clerical and technical employees at Harvard University, for instance, the union campaigned on the slogan "It's not anti-Harvard to be pro-union." While union organization has gained favour among white-collar and professional workers, it tends to be limited to teachers and government workers.

Attempts to unionize white-collar workers

Sometimes employers voluntarily recognize the union or remain neutral in the election process. This is most often the case in the public sector. Some private-sector employers have voluntarily recognized unions in new establishments in return for union cooperation and participation in the task of designing the work system, training the work force, and starting up operations. Such accommodation, however, is the exception in the United States; the typical picture of an organizing drive is still one of aggressive union campaigning in the face of aggressive employer opposition.

The more adversarial the organizing campaign, the more likely it is that the bargaining relationship will develop along similar adversarial lines. Conversely, the less resistance to organizing by the employer, the higher the likelihood that the union–management relationship will evolve along cooperative lines. For example, one large manufacturing company that voluntarily recognized a union in the 1940s, and has remained neutral in organizing drives held in new plants opened since then, has experienced only one brief strike in its entire history. This record stands in marked contrast to the pitched organizing battles and frequent strikes experienced over the years in the rubber, meat-packing, and coal-mining industries.

COLLECTIVE BARGAINING

What effects do unions and collective bargaining have on the outputs of the employment relationship that are of greatest interest to workers, employers, and the larger society? The historical evidence is that unions improve the wages, hours, and working conditions of their members. Perhaps the biggest and most direct effects have been on wages and fringe benefits; estimates indicate that unions have raised the wages and benefits of their members by 15 to 30 percent above those of comparable nonunion workers. Unions have also pioneered over the years in introducing an expanded array of fringe benefits such as paid vacations, sick leave, pensions, seniority provisions, apprenticeship and training programs, and grievance procedures for resolving conflicts on a day-to-day basis.

Assessing the effects of collective bargaining on the goals of the firm is a more difficult task. Historically, unions have served to encourage greater formalization and professionalization of personnel management practices. By increasing wages and related labour costs, unions have also encouraged employers to take actions that improve labour productivity. But the evidence is that, overall, unions reduce returns to shareholders, in part because they increase the cost of labour. These effects vary considerably, however, depending on the relationship that evolves between labour and management.

Some behavioral scientists distinguish between "distributive" and "integrative" bargaining. Distributive bargaining is essentially a win–lose engagement. What one party "wins" through hard bargaining comes at the expense of the interests or goals of the "losing" party. In contrast, with an integrative bargaining approach the parties engage in cooperative problem solving in an effort to achieve a resolution from which each party benefits.

In reality, most bargaining relations are mixed-motive in nature; that is, they have both distributive and integrative features. In the 1980s, however, the pressures on labour and management to solve complex problems intensified and therefore strengthened the efforts of many unions and companies to develop integrative relationships. The scope of labour–management relations expanded to include more opportunities for employee participation and union consultation in managerial decision making. Again, these innovations did not spread to large numbers of bargaining relationships. Instead, sustained innovation and cooperation tended to be limited to environments in which the economic pressures for change were intense and the company was willing to share influence and power with the union and accept union leaders as joint partners in the enterprise.

The workplace in different cultures

Do the principles of organizational behaviour and industrial relations apply universally across nations and cultures? This issue not only has fascinated scholars and policymakers but, at critical points in history, has influenced the course of international events. After World War II, for example, the head of the U.S. forces occupying Japan imposed American-style labour laws and industrial relations practices under the belief that they would help ensure that Japan would not fall back into a militaristic or totalitarian state. By the 1980s the situation had reversed. Many American experts called for adoption of Japanese management practices in hopes of achieving the same high productivity, quality, and cooperative labour–management relations found in leading Japanese firms.

In both of these instances some practices were effectively transplanted to the other country. Free trade unions and collective bargaining did evolve in postwar Japan, albeit not in the same fashion as they had in the United States. The success of Japanese management did spur many American firms to reexamine their own policies and practices and to implement many of the principles underlying the Japanese system. This has been especially true in American manufacturing industries. In the auto industry, for example, the success of Japanese "transplants" (Japanese-managed plants operating in the United States and staffed with American workers) has convinced American auto executives that such practices as the use of teams to organize work, labour–management cooperation, worker participation, training in quality control, and just-in-time inventory systems result in higher quality and productivity than do traditional American practices.

However, the specific practices found in one country are hard to imitate exactly in another. To understand why and to explain why practices vary among nations, one needs to consider differences in national cultures, political and economic conditions, timing of the industrialization process, and key historical events that affect different countries. The comparative analysis that follows briefly reviews how these factors have influenced developments in the United States and compares their role in shaping the evolution of industrial relations in Japan and Germany. These countries are often compared because all three have achieved high rates of economic growth, productivity, labour peace, and improvements in workers' standards of living, yet these results have been achieved with very different institutions and practices.

THE UNITED STATES

Perhaps the value most closely identified with American culture is individualism. The importance of individualism can be seen in organizational systems of authority and conflict resolution, where subordinates are expected to question orders of superiors and attempt to resolve differences in a one-on-one fashion. The expected response to individual ambition and achievement is reward and promotion, and individuals normally turn to collective actions only when frustrated with organizational responses to individual efforts.

The broader economic and political context in which organizational and industrial relations developed has been one that places a high value on the role of the free market and keeps government intervention in private enterprise to a minimum. This ethos was particularly strong during the period of rapid industrialization between the late 1800s and the 1920s. The economic and social shock of the Great Depression modified this position considerably, however, and since then the American public has expected the government to play a more active role in regulating economic policy and industrial relations practices. Still, the view favouring decentralized institutions, industrial self-governance, and free enterprise has kept industrial relations focused at the level of the firm.

Given these values, it is not surprising that the greatest conflicts in American industrial relations tend to arise over efforts to unionize a company and over negotiation of the specific terms of an employment contract. The value Americans place on individualism and mobility also helps explain why turnover rates tend to be higher in American firms than in many other countries and why cooperative labour–management relations are difficult to sustain.

Margin notes:

Distributive and integrative bargaining

Transplanting national organizational practices

Free enterprise

Shimada Haruo, a leading Japanese industrial relations scholar, has maintained that Japanese industrial and organizational practices cannot be comprehended until one recognizes that Japanese managers regard human resources as the one critical asset affecting the performance of Japanese enterprises. Therefore, management in the large Japanese companies is deeply committed to developing and sustaining effective human resource programs. While some assume that this practice grows out of Japanese culture and traditions, Shimada argues that organizational relations in Japan are shaped by the interactions of cultural, economic, and political events.

Japanese culture does place a high value on family relations and obligations, and some analysts claim that this family model carries over into the workplace. Employers are expected to show the same regard for their workers that a parent shows for other family members. Unity within the firm becomes a central value and corporate objective. In turn, employees are expected to show strong loyalty to their employer. It should be noted, however, that employment relations can be quite different in the smaller Japanese firms that supply the giant producers and exporters. The smaller companies have a tenuous existence and cannot guarantee secure employment or make substantial investments in employee training.

Emphasis on the group

Employees in the large Japanese firms are less affected by individualism and place more emphasis on group relationships in the design of work and their day-to-day workplace interactions than do their Western counterparts. Direct conflict in organizational decision making is discouraged in favour of a more informal consensus building. Authority is respected so highly that the outcomes of group problem-solving tasks tend to reflect the views or preferences of senior managers.

Prewar industrial relations. From the early days of industrialization, Japanese employers, labour leaders, and bureaucrats were divided over whether Western-style conflicts between management and labour were inevitable and whether Western models of unionization and dispute resolution were appropriate models for Japan. Many employers (and, in the nationalist 1930s, some labour leaders) argued that Japan's "beautiful customs" of benevolence from superiors and loyalty from subordinates made the Japanese family a more appropriate model for industrial enterprise. Between 1920 and 1931 government policymakers brought forward eight proposals to provide a legal framework for the establishment of labour unions, but each was defeated by vigorous opposition from employers' associations and conservative politicians. At its peak in 1931, the prewar union movement had reached only 7.9 percent of the total industrial labour force. Large-scale enterprises were particularly successful in forestalling the formation of unions, and several developed alternative "Japanist" models of paternalistic management. It was the advent of World War II, however, that brought the union movement to a halt.

Postwar industrial relations. Japan's rapid economic growth from the mid-1950s through the 1980s propelled its industrial relations and organizational practices into the centre of international attention and debate. Three interrelated features of the Japanese system have attracted the most attention: (1) enterprise unions, (2) high levels of labour–management cooperation and cross-functional problem solving, and (3) lifetime employment security.

Enterprise unions. In the immediate postwar period, the lifting of restrictions on unionization resulted in a wave of labour activism and unrest. Alarmed by the radicalism of the industrial union movement and the active involvement of the Communist Party at the movement's national level, the Japanese government and the American occupation authorities launched a counteroffensive (the "Red Purge" of 1947–48) to deny union rights to communist-backed organizations. The newly formed Japan Federation of Employers' Associations (Nikkeiren) embarked on a campaign to form moderate, anti-communist enterprise unions that included lower-level management personnel as well as workers.

Employers made important concessions to the labour movement, including employment security, seniority-based wage systems, and twice-yearly bonuses negotiated each year along with base-pay increases. These accommodations provided the foundation for industrial relations in the large-scale enterprises that led Japan's remarkable economic growth from the mid-1950s to the mid-1970s. Even the slowdown in growth that followed the 1973 oil crisis did little to shake the implicit security of employment. Those industries that faced the most severe business declines—shipbuilding, steel, aluminum processing, and petrochemicals—undertook to cushion the inevitable reduction of employment through outplacement programs (often in cooperation with affiliated companies), government-subsidized retraining programs, and diversification.

Labour–management cooperation. The low level of conflict even in declining industries is an indicator of the generally cooperative relationship between management and labour that characterizes Japan's large private-sector firms (in contrast to the more conflictual relations in the public sector). Because blue- and white-collar workers belong to the same union, there are fewer lines of demarcation between these groups. In most enterprises, for example, the scale of management bonuses is tied to the size of bonuses for blue-collar workers. Many senior Japanese executives have been union leaders in their company at an earlier stage in their career.

In part because the union leader of today may well be the manager of tomorrow, large firms generally practice union–management consultation over broad strategic decisions. They also endeavour to elicit employee participation in day-to-day problem solving and quality improvements in the workplace. Quality circles and employee suggestion systems are widespread. Problems in product and technological development are more easily solved by employing cross-functional teams and by a career development strategy that provides engineers and managers with job experience in multiple functions, including working on the factory floor.

Problem solving

Employment security. Lifetime employment security is not guaranteed by law or contract but is embedded in the business and human resource policies of large firms. Recruitment, training, compensation, and internal promotion policies are designed to facilitate lifetime employment. Growth in company size and stabilization of employment are high priorities for Japanese executives. Generally, Japanese firms accept the stakeholder view of corporate objectives more readily than do their American counterparts. (A stakeholder can be anyone with an interest in the firm, be it an employee, a customer, a supplier, a shareholder, or even a concerned citizen.)

In most large Japanese firms, employees are hired immediately upon completion of their education and are expected to stay with the firm until they retire. In return the company invests heavily in employee training and development. Layoffs are carried out only as a last resort, even during periods of technological change or a downturn in the business cycle. Wages in Japanese companies tend to rise with seniority, and most job openings within the blue-collar and managerial ranks are filled through internal promotions rather than by hiring from the external labour market. These combined features limit the likelihood that workers or managers will make mid-career transfers to other companies, because the cost of leaving a firm that offers lifetime employment security would be too high.

It should be noted that these aspects of Japanese employment relations do not apply to all firms or all workers. Many smaller companies employ retired workers, immigrants, women, or those who have not found work or have lost their jobs in the large firms. While the law forbids discrimination against women and minorities, Japanese women have been excluded from the lifetime employment system and from higher-level jobs in corporations.

GERMANY

The industrial relations system of the Federal Republic of Germany presents an interesting contrast to both the American and Japanese models. The key characteristics of the German system are (1) industrial unions and indus-

trywide collective bargaining, (2) formal structures for employee representation in management decision-making processes, and (3) the close integration of formal education and training with human resource practices within firms.

Unlike their Japanese counterparts, few scholars of German institutions emphasize the centrality of culture when characterising industrial relations in Germany. Instead, attention focuses on the legal framework and organizational structures created in the aftermath of World War II, but that does not dismiss the influence of German culture, which is evident in the strong work ethic and the deep respect for the values of community and authority.

German cultural values

These qualities can be seen in the industrial relations system that began to emerge during the time of the Weimar Republic, between 1919 and 1933. The factory came to reflect the values of the society and to serve as an industrial community or plant family. In 1918 a compromise was reached between the ruling authorities and the German labour movement in which unions were recognized by the government and employers. In return unions accepted the basic rules of a capitalistic economy despite their socialist rhetoric to the contrary.

Labour unions. Nazi rule from 1933 to 1945 suppressed free trade unions. Following World War II, the country was divided into the German Democratic Republic (GDR) and the Federal Republic of Germany (FRG). In the GDR, or East Germany, most workers were represented by the state-approved Free German Trade Union Federation. The federation represented both blue-collar and white-collar workers, and by 1985 it achieved a membership of about 9.4 million, or about 96 percent of the East German work force.

In the FRG, or West Germany, once a democratic form of government was reestablished after the defeat of Nazism, the basic patterns of management and worker relationships initiated in the prewar era reemerged. A system was established that encouraged each political party to assert its interests through a combination of political pressure for legal rights, formal negotiations, and cooperation within the enterprise. In this climate, West Germany's postwar labour movement paralleled the union structures that were developing in the U.S. manufacturing sector. Unions came to represent about 40 percent of the West German labour force.

A sharp drop in union enrollments in the 1990s brought membership in reunified Germany down to about 25 percent of the labour force. Today German unions operate on an industry-level system of collective bargaining, and firms within each industry are represented by employer associations that serve as their bargaining agents with the industrial unions.

Government policy supported industry-level bargaining by enacting legislation that extended the basic wage and fringe benefit patterns negotiated in collective bargaining to cover workers in the nonunionized firms of each industry. These industry-level negotiations are supplemented with tripartite (government–union–employer) consultations at the national level over larger economic, social, and employment policy issues. Industrial relations in Germany reflect a respect for employee rights and a preference for negotiation rather than open conflict or challenge to authority.

Consultation and codetermination. In addition to collective bargaining, both union and nonunion German workers are represented formally by works councils that are required by law to exist within larger establishments. Works councils are representative bodies elected by all the employees in an enterprise. Management must consult with works councils on a broad range of human resource issues, including questions of adjustment to technological change, safety and health, training, and layoffs.

German law also provides for a system of "codetermination," or worker representation, on the supervisory boards of large companies. These boards function in a fashion that is similar to the boards of directors in U.S. firms. The supervisory board appoints executives to top management positions. One of these top managers is the *Arbeitsdirektor,* or personnel director; this person must be approved by the majority of the worker representatives who sit on the supervisory board. Consequently, by providing workers with a voice at the highest level of managerial decision making in large companies, German law and practice institutionalize a stakeholder view of the corporation. For Americans, this stands out as the most distinctive—and controversial—feature of the German industrial relations system.

Representation on supervisory boards

Education and training. The starting point for human resource practices in German firms is the country's highly structured education and apprentice-training system. Tracking begins at age 10, when a small percentage of the most academically talented students (most of whom do not come from working-class families) enter a college preparatory program and later go on to obtain university degrees and jobs in their chosen profession. About 70 percent of German students are tracked into a vocational education and training system. At age 15 those in this track begin a three-year apprenticeship program in which they spend part of their time participating in on-the-job training in German companies and part of their time in classroom instruction. Upon completion of this apprenticeship they are certified in their trade. Further occupational mobility at later stages of a worker's career depends in large part on receiving additional training and professional certification. This system therefore provides considerable general training that is transferable to other enterprises and thus makes it possible for workers to move from one firm to another.

The high degree of skill training combined with a strong work ethic reduces the need for close supervision. Studies have shown that German firms tend to have fewer supervisors than are typically found in comparable concerns elsewhere in Europe or in America. Finally, the heavy role that business enterprises play in the training and socialization of their workers helps explain why surveys have found German workers to be deeply committed to their jobs and to exhibit strong allegiance to their organizations.

COMMON CHALLENGES

Together, comparisons of the American, Japanese, and German models illustrate that, while each country fashions institutions that are consistent with its unique culture and with its economic and political environment, all industrial relations systems must deal with the same fundamental issues. They all must devise policies and institutions to meet workers' expectations, to provide them with a voice at the workplace and in political affairs, and to resolve conflicts that inevitably arise between workers and employers. How well an industrial relations system performs these functions has a major effect on the welfare of individual workers, their employers, and the society in which they live.

(W.F.Wh./T.A.K./Ed.)

LABOUR ECONOMICS

Labour economics is the study of the labour force as an element in the process of production. The labour force comprises all those who work for gain, whether as employees, employers, or as self-employed, and it includes the unemployed who are seeking work. Labour economics involves the study of the factors affecting the efficiency of these workers, their deployment between different industries and occupations, and the determination of their pay. In developing models for the study of these factors, this section deals with the labour force of contemporary industrialized economies.

The economist cannot study the capabilities, jobs, and earnings of men and women without taking account of psychology, social structures, cultures, and the activities of government. Indeed, these forces often play a more conspicuous part in the field of labour than do the market forces with which economic theory is mainly concerned. The most important reason for this arises from the pecu-

The influence of non-market forces

liar nature of labour as a commodity. The act of hiring of labour, unlike that of hiring a machine, is necessary but not sufficient for the completion of work. Employees have to be motivated to work to an acceptable standard; the employment contract is, in effect, open-ended. This may be no problem when employees are weak and easily replaced, but the more skilled, organized, and indispensible they are, the more the care that must be given to creating an institutional setting that will win their compliance and meet their notions of fairness.

A second major reason for looking beyond straightforward labour market forces is the often highly imperfect nature of the industrialized labour market. The majority of jobs are occupied by the same employees for many years, and only a small minority of employees quits their jobs in order to move to a comparable job that is better paid. Studies in a number of countries have all revealed substantial variation in the level of pay offered for the same job by different firms in the same local labour market. This sluggishness of labour market response is particularly notable for more skilled labour and for labour employed by firms in strong product market positions. The main thrust of competition in many instances comes not through the labour market but through the product market, with an employee's pay being determined less by what the job is than by who the employer is.

In discussing both market and nonmarket forces in labour economics, the following discussion poses them not as alternatives but as complementary explanations. The difference in pay between, for example, a craftsman and the labourer who works alongside him may be fixed by custom, an arbitrator, a job evaluation system, or a bargain with a trade union. In their different ways these are far from being merely passive agents through which market forces are transmitted into human behaviour. They may, for instance, shape the market by defining its categories of labour. Also, they may differ greatly in their speed and extent of response.

The comparative study of wage movements in different periods and countries does show many similarities and regularities that are more marked than the variety of their settings would lead one to expect. This evidence of the influence of persistent forces working within an equilibrating system is one justification for the economist's speaking of a labour market. But there is much in labour that can be understood only with the aid of the psychologist, the sociologist, the historian, the labour lawyer, or the political scientist. Depending upon both the circumstances and the purpose for which the explanation is required, it is an empirical question how far the forces that these scientists study might interact with the market forces that are the special province of the economist.

Quantity and quality of the labour force

The size of a country's labour force, within a given total population, depends on two factors: the proportion of the total population that is of working age and the proportion of these who work for gain.

The limits of working age are usually taken to be established by the minimum school-leaving age and the prevailing pensionable age. Allowance must then be made for those persons who continue to work for gain after attaining pensionable age. Typically, some two-thirds of the population of an industrial country lies within these limits.

The employed labour force may be characterized by particular activity rates. An activity rate is the proportion of the whole number in a given age and sex group—for example, females aged 30–34—who work for gain. Among males, activity rates in the earlier years of working age are as a rule low, because so many remain in education and training. Between the ages of 25 and 50, male activity rates approach 100 per cent, but from 50 onward they fall as men begin to retire. The pattern of female activity rates is very different and has changed greatly in the second half of the 20th century. Formerly, female rates ran higher than male in the earlier years because fewer girls enjoyed

extended education, but from the age of 20 onward they fell sharply as women married and withdrew to domestic duties. Women so occupied remain by far the largest contingent of persons of working age but not in the labour force. Since World War II, however, it has been less usual for women to leave paid employment immediately on marriage. A fall in the age of marriage, moreover, together with a smaller size of family, has enabled many women to return to paid work in their 30s, and female activity rates have come to show a second peak between the mid-30s and the mid-40s, after which they decline more steeply than male rates. From these various activity rates there emerges an overall proportion of the gainfully occupied among all of working age that is typically in the region of two-thirds.

The quality of the labour force depends on education and training, physique, and health. There is evidence that physique has been greatly improved by increases in the standard of living in the 20th century. Because of the reduction in family size, this rise has been even more marked for children than for adults, and the effects have been seen in the greater height and weight attained by children at a given age. The beneficial effects of stronger physique on health have been enhanced by the advance of medical knowledge and the increased availability of medical services. Better health has raised productivity by a reduction in absenteeism and by a prolongation of the working life during which the economy reaps the benefit of the education and training the worker has received.

Education and training can be regarded as a kind of investment, and the rate of return it yields can be estimated. The amount of the investment is the value of the student's use of resources—buildings, equipment, and instructors— together with the output that the economy would have enjoyed from work had the student been gainfully occupied rather than studying. The yield, in turn, is calculated by assuming that the average subsequent earnings of those who completed a given course of education, compared with the average earnings of those who stopped just short of it, provide a valuation of the increase in productivity that the course confers. From this difference in earnings there must be deducted the contributions to the sinking fund required to replace the amount of the investment by the end of the student's working life. The net yield so calculated can then be expressed as a rate of return on the investment. Estimates suggest that this rate of return is not less than that generally obtained from investment in physical capital. They also indicate that a great part of the productive resources of the economy consists in the education and training embodied in its labour force.

Investing in education and training

Though estimates of this kind are subject to some objections in principle, they do serve a useful purpose in stressing the potential of education and technical training in raising productivity and the risk of investing too little in them relative to other forms of investment. There is no less a risk of underinvestment in training in industry. The great obstacle there is that the employer is not assured of retaining the services of workers in whose training he has invested. Employers generally follow one of two strategies. They may provide training in-house and seek to retain the employee by inducements such as the prospect of career progression, pension entitlements, and other devices designed to encourage loyalty and an "organizational orientation." Or, alternatively, employers may combine to establish industrywide training arrangements, sometimes with statutory support, thereby permitting ample skilled employees for easy movement between firms and more of a "market orientation" in their work forces.

Deployment of the labour force

The contribution of education and training to economic development is apparent in the changes that have taken place in the deployment of labour in the developing economies. When the deployment of the labour force is followed over a period of time, certain patterns appear. One of these arises from changes in methods of production.

Shifting patterns of employment

In farming, improvements in technique and equipment have made possible an increasing output from a declining labour force. In industry, the extension of research and development, the increased complexity of products and equipment, and new methods of collecting, storing, and processing information, along with other developments of management procedures, have all acted to increase the numbers of administrative, clerical, and technical workers relative to manual workers. A second course of change has affected occupations linked with particular industries, when those industries have contracted or expanded as compared with others. Coal mining and cotton textiles are examples of contraction. The service industries, on the other hand, have expanded: a greater proportion of household expenditure is devoted to services; education has extended; governments have provided more social services. A third course of change has its origins in relation to supply. Domestic services, for instance, have contracted because improved education and the opening up of other occupations to women has enabled many to take up work that they prefer. One general tendency is that as standards of living rise the service industries absorb a greater proportion of the labour force, because the rising demand for their output is not generally offset, as in manufacturing, by a progressive reduction in the amount of labour required to produce a given output.

The far-reaching changes that have come about in the relative numbers in different occupations and industries have called for corresponding changes in the training and allocation of young entrants to employment and for the movement of workers already in employment to other kinds of work and, often, other places. Though part of this adaptation has been unplanned and undirected, a number of governments have undertaken to foster the process of adaptation by a labour-market policy. One means of applying this policy is the provision of information to job seekers as to vacancies immediately available, and to workers at large as to the prospects and requirements of particular occupations. Labour-market policy also tries to guide entrants toward those occupations for which an expansion of demand is expected. One way of doing this is by promoting the training and retraining of selected persons for selected occupations. The function of retraining may be extended, as in Sweden, to offer all workers opportunities to qualify themselves for better-paid jobs throughout their working lives.

Fixing rates of pay

Wages may be fixed by collective bargaining between unions and management or by individual bargaining between worker and employer or simply by custom. When the status of wage earner became distinguished from other forms of labour, it was marked by the existence of an individual agreement about the rate of pay between wage earner and employer. The law still recognizes the individual contract of service even where the rate of pay has been fixed collectively. In earlier days there was often not even individual bargaining, because customary rates of pay prevailed that might be unchanged for many years at a time. In southern England, for instance, the prevailing rate for building craftsmen remained at sixpence a day for 120 years after 1412; for most of the 500 years after 1412, the building craftsman's rate was half again as great as the labourer's, or nearly so.

After industrialization had set in, custom continued in some measure to regulate rates of pay and to protect workers who entered into individual agreements. But its sway was much less extensive: from time to time rates changed. Although there was at first no reference to the cost of living, when price increases were general and sustained, there must have been informal understandings among the wage earners of a locality that each in making his own agreement would hold out for a higher rate. At times of increased demand for labour, moreover, the employer would have to offer a rate sufficient to attract and retain the wage earners against the competition of other employers. The necessity of holding needed labour is today the governing factor for employers who have workers with

Customary rates

whom they do not negotiate either collectively or individually—generally clerical and administrative workers.

Frequently where the safeguards both of custom and of competition for workers have been missing, workers have felt the need to combine in order to bargain collectively. The force of custom declined as industrialization created new jobs and moved workers into new localities. Business fluctuations brought unemployment so that instead of employers competing for labour, workers were often competing for jobs. Thus industrialization has been universally associated with the rise of trade unions. (See below *Organized labour: Trade unionism*.)

TRADE UNIONS AND BARGAINING AREAS

A main purpose of the trade union was to maintain a minimum rate of pay for its members, a purpose that led unions to extend or delimit both their membership and the number of employers with whom they bargained. The starting point was typically the club of craftsmen in a certain locality, concerned to ensure that none of its members worked for less than the rate it recognized from time to time as a minimum and to raise that rate when opportunity offered. By bringing all who worked in the same craft and district into membership, the club could reduce the risk of their bidding against each other; and if it could also limit the number entering the craft—by controlling the number of apprentices—it would be more likely to be able to raise the rates. However, since it was still likely to be subject to the competition of members of the same craft coming in from other places, and some of its own members might move in search of work, it had an interest in extending its coverage over all members of the craft throughout the labour market.

Representing all craftsmen within a market area

If the labour market was not coextensive with the product market, however, the union might still find itself exposed to the competition of workers at a distance if these worked at lower rates and so enabled their products to be sold at lower prices. Thus there was reason to extend the coverage of the union up to the boundary of the market for the product, though it was not practicable to organize workers in other countries. However, the union would see no advantage in bringing workers of other occupations into membership: on the contrary, it was felt that one could expect employers to concede a rise more readily if it would have to be paid to only a restricted membership. What has been said here of the craft union applies to all unions insofar as their aim is to maintain and raise the pay of members of a given occupation: the pursuit of that aim will lead them to embrace all the members of the occupation throughout the market for their product and to establish a basic rate throughout this bargaining area.

The reactions of employers both reinforce and modify this tendency. The ability of any one employer to pay a given rate depends largely on what rates are being paid by other employers who compete in the product market. When competition is close and labour costs are a substantial proportion of total costs, all employers selling in a given product market have a strong inducement to negotiate only through an employers' association that embraces them all. Most employers' associations are in fact industrywide, though some are limited to particular regions or sectors of an industry. Employers also know that what is conceded to employees in one occupation will commonly be demanded by those in others, unless they are divided by such a gulf as used to separate the manual from the clerical workers. Employers therefore commonly prefer to reach an agreement with all their workers in common and may make this a condition of negotiation. They thereby put pressure on occupational unions either to extend, amalgamate, and divide up until they form industrial unions each embracing all the manual workers in a given industry, as the Swedish unions have done, or to enter into confederations that provide all the unions having members in a given industry with a common front for the purpose of bargaining—the course followed by British unions.

Many semiskilled and unskilled workers are unable to seek bargaining advantage by restricting the membership of their unions to one defined occupation: they have to

Organizing all workers within an industry

seek it rather through the accumulation of funds and the force of numbers—for them, "unity is strength." Some unions have therefore adopted the principle of industrial unionism from the outset, in accordance with the tendency noted above toward establishing industrywide bargaining areas. Others, the general unions, have set out to recruit workers from every occupation and industry; but for bargaining purposes they have commonly had to act on behalf of their members in each industry separately. In any clash between the forces delimiting the bargaining area and those delimiting the trade union, the former generally prove the stronger.

EFFECTS OF COLLECTIVE BARGAINING

Collective bargaining developed with the growth of trade unionism, especially from 1890 onward. It impinged upon labour markets in which the trend of money wages was upward: in years of good business, money wages generally rose, and though in the years of falling or low activity they were often cut, the cuts were generally smaller than the preceding rises had been.

Leveling of pay rates. A first effect of the extension of collective bargaining was to reduce pay differences, which had been large, between the wages a given grade of labour received at any one time in different regions and in different firms in the same region, and even between one worker and another under the same employer. The unions at first had to accept the prevailing regional differences, but their pressure to bring up the lower-paid regions has reinforced the effect of improved communications and information in reducing these differences greatly, especially since World War II. Assurance of "the rate for the job" raised the wages of particular groups or individuals who lacked access to alternative employers, either spatially or because of their lack of information and mobility. In general, the extension of collective bargaining brought about greater uniformity in the rates of pay received by workers of a given grade, and it did so by raising the lower rates.

Collective bargaining has also affected the forms in which improvements in pay are realized. It has borne particularly on those parts of the terms and conditions of employment that of their nature require to be regulated collectively. Chief among these are the hours of work. The extension of such fringe benefits as insurance and pensions paid for by the employer has also reflected trade union pressure.

Raising the level. Studies of differences between the movements of wages in unionized and nonunionized sectors of employment, especially in the United States, have brought out three other effects of the extension of collective bargaining. One is an impact and once-for-all effect: the introduction of collective bargaining has raised the wages of the workers concerned, relative to the general level prevailing around them, by some 10–15 percent. A second effect has been in the timing of changes: when wage rises were the order of the day, unionized workers achieved them earlier than nonunionists; and when the market was moving the other way, cuts of unionized workers were put off longer. When the cost of living has risen rapidly, as in wartime, the unionists' ability to secure compensatory rises in money wages more promptly promoted the extension of unionism, especially among white-collar workers who had previously stood aloof from it. The third effect has been in the ability not only to defer wage cuts in depression but also to reduce their amount. In the United States, for example, the differential between wages in the unionized and nonunionized sectors was at its highest in the 1932 depression trough. A major effect on the general level of pay in terms of purchasing power and on its share in the product of industry seems to have stemmed from the resistance to pay cuts in the world economic depression of 1921: though pay was cut severely, often after protracted struggles, it could not be brought down as far as product prices had fallen, and in more than one country the distribution of the product of industry between pay and profit seems to have been permanently shifted.

Limitations. By raising the pay of particular workers and by modifying fluctuations in the workers' favour, over a period of time collective bargaining has made the total of

Advantages over nonunion pay rates

pay higher than it would have been otherwise in the same conditions of the market. But the effect has been limited. Before World War II the movements of the general level of pay continued to depend mainly on market conditions, and the points at which the effects of collective bargaining can be distinguished clearly are fewer than might be expected. Collective bargaining provided the arena in which market forces took their effect, rather than a shelter from or alternative to them.

After World War II, however, the bearing of market forces on collective bargaining changed. One important influence was full employment (at least until the 1970s), but others were the increased importance of governments as employers, an apparent diminution of the significance of labour cost in product market competition, and, from the 1970s, the floating of national exchange rates. Employers gained the expectation that if they agreed to rises in pay that would exceed the rise in productivity, and so raise unit costs, they would still be able to preserve profit margins by raising the prices of their products—and do this without losing business, provided only that the initial rise in pay was not greater than that which was being conceded at the time by other employers. Some countries, such as Sweden and West Germany, had employer organizations that were sufficiently united to resist these pressures. Other countries with little employer solidarity and highly fragmented bargaining, such as Britain and Italy, suffered persistently high cost inflation. Thus, the impact of trade unions cannot be assessed in isolation from that of employers.

A second limitation is that, even where collective bargaining has affected the movement of money wages, it has had only transient effect on the division of the national income between pay and profits. Whatever the course from time to time of rates of pay in money, the pay per person in real terms (*i.e.,* in terms of purchasing power) has risen with remarkable regularity in much the same proportion as output per person, save for the one major exception of the displacement in favour of pay in the early 1920s. It appears that firms take advantage of opportunities to restore profit margins either by maintaining their selling prices while productivity rises or by raising those prices. A rise in real pay initially conferred by any one rise in money pay, therefore, will be reduced as the cost of living rises.

Division between pay and profit

THEORY OF BARGAINING

Limitations on the scope of bargaining are also suggested by theory. Collective bargaining can be seen as the reduction of two risks to which the worker is exposed through individual bargaining. There is first the risk that the worker will be merely one of a number of applicants for a single vacancy and that competition between them will force the pay down. Even as the sole applicant for the vacancy, there remains the second risk that the job will be offered only on terms that are unacceptable; in the event of failure to agree, going without the job will inflict more hardship on the worker than not filling the vacancy will on the firm. Bargaining through a trade union removes the first risk by ensuring that whichever applicant the firm engages it must pay not less than the union rate: in this sense the union exercises monopoly power. Membership in a trade union reduces the second risk by increasing the workers' relative power to change proffered terms by withholding consent: in this sense the union confers bargaining power.

Constraints of supply and demand. The scope of the monopoly power that the union exercises by maintaining the rate for the job may be seen by supposing that this rate is simply announced by the union, which leaves firms to hire as many or as few people as they choose at that rate. In deciding how high it can set the rate, the union must have regard for the consequences for employment. Firms may be able to alter the design of the product and the method of production so as to use less labour. To the extent that they cannot economize in the use of labour and that the pay of this labour enters into the total cost of production, a higher cost arises that firms may be obliged to pass on to their customers through higher product prices. The customers are then likely to buy less from them, especially if there is international competition

in the markets for the product, and again employment will suffer. Thus a union that dictates its own terms is still subject to the constraint of the demand curve for the labour concerned. Equally, if the employers dictate the rate of pay, they could not set it so low as to make it impossible to attract and retain the required labour force: they would be subject to the constraint of the supply curve of the labour concerned.

The costs of work stoppages. When neither side dictates the terms and an agreement must be negotiated, failure to agree results in a stoppage that causes losses to both parties. Attempts have been made to develop the pluses and minuses of these losses into a theory of bargaining. If, for example, it is assumed simply that the continuance of a stoppage progressively increases the wish of the parties to end it, and so causes firms to raise and the union to lower the rate at which each is prepared to settle, then the stoppage will end on the day when the two rates have been brought into equality. Further, if the parties agree in their forecasts of how the wish to settle will be affected by the continuance of the strike, they will find it in their interests to reach agreement on what would be the terms of the ultimate settlement without resorting to coercion by stoppage. A more elaborate theory has been developed in which each party is seen as weighing the cost to itself of a stoppage of given length, the benefit to it of a given concession by the other party, and its estimate of the effect of a given extension of the stoppage on the willingness of the other party to make a concession.

Influence of non-market forces

In practice much more is involved—internal political pressures, for instance, personal prestige, or the tactic of involving the government and public opinion. Many of the costs of a stoppage, moreover, are hard to express in terms of money. The above three variables must always figure prominently in the parties' consideration. A stoppage is unlikely when on a consideration of these variables it appears that there will be no net gain; this situation exists when bargaining power is evenly balanced or when negotiation has already brought the parties' positions close together. One party is likely to see a clear advantage in a stoppage only when, market forces are working in its favour, and these will have told already in the course of negotiation. In particular the cost of a stoppage will be high to employers when they are busiest, whereas in a recession a stoppage may be a positive benefit to them. Insofar as bargaining power is thus conferred by market forces, it injects no distinct factor into the determination of rates of pay. Bargaining power may also be conferred by determination, loyalty, and leadership on either side. It has also been conferred on trade unions by the expectation, engendered among employers by the experience of sustained full employment, that rises in pay can be covered by higher prices so as to maintain profit margins without loss of business.

METHODS OF PAYMENT

The productivity of a work force depends to a substantial extent upon the successful management of its payment system. Employees generally judge the "fairness" of their pay not by its absolute level but by its level relative to that of other employees, and in particular those with whom they are in close proximity. Their criteria for fairness are generally very conservative; the fair pay differential is the one to which they have become accustomed. A disturbed differential can be a source of discontent and lack of motivation. The technique usually used for managing the internal pay structure, as the relative pay of occupations within an organization is called, is job evaluation.

Job evaluation. This term covers a range of procedures used to develop and maintain a consistent internal pay structure that is acceptable to the work force. Ranking methods use surveys of the work force's preconceptions of fairness to arrive at a comprehensive pay structure. Analytic methods score the requirements of different jobs according to distinct criteria such as physical effort, mental skills, responsibility, and working conditions and then use weighted averages of these scores to establish the final pay structure. Job evaluation is typically participative, methodical, and ponderous. It offers a means to legitimate

a pay structure and a procedure whereby changes in that structure can be negotiated and implemented. As such, it is a defense against the effect of disturbed pay differentials on employee motivation.

Pay incentives. By contrast, there are a great variety of devices that use pay as a positive motivator. The most common method of payment is according to the duration of time worked—by hour, week, month, or year. But additional merit payments may be added on at the discretion of management as rewards for good performance. The hazard here is that, if employees feel the criteria on which these are based are inconsistent, the effect may be negative.

Salary structures are more formal devices that offer a range of pay levels for different job grades. The employee's position within the range may depend upon managerial discretion, or it may be formalized into automatic annual increments. Promotion between job grades depends upon criteria over which managerial discretion has stronger incentive effects.

Piecework and standard times

Payment by results most commonly relates money payment to physical output for a part of the wage. This may be done for an individual as piecework or for a group of workers. In order that the incentive effect be seen as fair for employees engaged on different tasks, it is necessary to develop common standards to provide the same rewards to comparable increases in effort. The work study techniques devised for this use a combination of accurate timing and the observer's judgment of the effort being applied over many repetitions of the job to arrive at a standard time, which is then directly comparable with the standard times for other jobs. This provides a basis for incentive payment, with the same bonus being earned by workers who complete their different tasks in the same percentage briefer than their standard time. In practice, there is ample opportunity for dispute and for the emergence of contentious anomalies, particularly as a result of minor changes in production technology. The incentive effect usually fades with time, and most payment-by-results systems have a limited life.

Payment related to corporate performance has become increasingly popular since the 1970s. Rather than linking employees' bonuses to their own performance, it is tied to profits or some other indicator of the state of the company. The main advantage of this is didactic; it is believed to increase loyalty and to educate the work force about the commercial circumstances within which the company operates. For similar reasons many governments have encouraged employee share ownership schemes.

Single-employer bargaining. In the United States, Japan, Great Britain, and a growing number of other countries, the scope of pay bargaining is often no greater than a single employer or even a single plant. This has the advantage that the wage structure and incentive system can be closely tailored to a broader package that includes training, motivation, and career development. It requires the employer to sever links with the multiemployer industrywide agreements that have often prevailed previously. It also implies that the trade union unit of organization is focused on the single firm as well—as a "local" in the United States, as an "enterprise union" in Japan, or as a "joint shop stewards' committee" in Britain. Such organizations enjoy considerable or complete autonomy from the wider union movement, making them in some respects weaker and more pliable.

Single-employer bargaining is a strategy that offers a firm greater freedom to manipulate the productivity of its work force by isolating its trade union (if any) and developing organization-oriented attitudes and company-specific training and job descriptions. It does not, however, provide the employer with any influence over the generally prevailing level of pay settlements. This is offered by the alternative multiemployer strategy, which also permits a more market-oriented approach to labour with industry-wide wage and training agreements. Multiemployer strategies do not imply complete uniformity of payment across all firms: in practice they tend to have discretion to vary the agreement somewhat at plant level. In some countries this is a fairly disciplined two-tier arrangement; in others,

local bargaining pressures cause the plant-level element to dominate in what becomes known as wage drift.

PUBLIC REGULATION OF RATES OF PAY

Minimum-wage laws. Governments have intervened in three ways to enforce minimum rates for workers who lacked both the protection of trade unions and competition between employers for their services and whose wages in consequence were regarded as needlessly low. One way has been to provide by law that "recognized terms and conditions of employment," such as those reached by collective bargaining for workers of a particular description, shall be applied to all others engaged in the same kind of work. A second way, followed by the United Kingdom since 1909 and by a number of state legislatures in the United States, has been to set up boards of representatives of the workers concerned and their employers, together with independent members, charged with determining rates of pay and hours of work that are legally binding as minimal on all employers within the scope of the board. The board discusses and negotiates wage claims in much the same way as in collective bargaining, albeit if the parties cannot reach agreement, the independent members have a deciding vote.

These two forms of intervention are calculated to raise the pay of particular groups of unorganized workers only to the extent that it would be raised by the extension of collective bargaining to cover them. A third way, followed notably by the United States in its Fair Labor Standards Act since 1938, has been to specify by statute the actual minimum wage applicable to wide categories of employment—the amount set being such that only a relatively small number of workers, namely the lowest paid, are immediately affected. When such measures were first proposed, critics argued that they would only result in the workers they were intended to protect losing their jobs. In some cases this has happened, as when the United States minimum wage was applied to the needleworkers of Puerto Rico. More often, however, the workers concerned were receiving lower pay than a competitive market would have afforded them—that is, if they had had more access to alternative employers. Minimum-wage measures tend to discourage labour-intensive methods of production, so that while they may cost jobs in the short term, they tend to force employers into more advanced production technologies, which create greater long-term growth and employment potential.

Costs and benefits of the minimum wage

Arbitration. Another way of regulating rates of pay is a by-product of arbitration systems set up originally as a means of avoiding strikes and lockouts. In Australia it has become the practice, accepted by both employers and trade unions, to have the main proportions of the wage structure and the movements of the general level of wages determined by the awards of arbitrators to whom these issues are submitted in the form of disputes. In setting rates for particular occupations or industries relatively to others, arbitrators must in practice have regard to what is acceptable to the parties; for even where arbitration is compulsory, its awards would cease to be observed if either party had cause to believe that the terms of the awards were persistently less favourable than it could obtain by its own bargaining power. In regulating the movement of the general level of pay, the arbitrators have more discretion; but the government, and the employers insofar as they meet international competition at home and abroad, will make them aware of the effects of the awards on the level of domestic costs and prices and on the balance of payments.

National incomes policy. Under full employment the rise in effective rates of pay has generally been inflationary in that it has exceeded the rise of productivity. The consequent rise in costs and prices has at times been disturbing domestically and has been particularly embarrassing to governments that face difficulties in balancing their external payments. Governments in general have been unwilling to check the rise of inflation by applying fiscal and monetary restraints to the degree that unemployment would be substantially raised. In the belief that at least part of the rise is due not to excess purchasing power but to the pushing up of costs and prices, governments have appealed to those who make decisions affecting labour costs and product prices to moderate the rise in pay and profits. Some governments have formulated norms that would, in theory, keep the general level of prices constant and would keep the general level of pay rising only at the rate of the expected rise in productivity—allowing, of course, for specific exceptions. Agencies have been set up to apply these principles, but usually only by way of investigation, assessment, and advice. Governments have preferred to rely on the acceptance of the policy in principle by employers and trade unions, and on their efforts to secure its observance by their affiliates. Even where statutory powers of control exist, they have usually been kept in reserve. During times of recession, such as those experienced in the 1980s, governments have generally suspended their efforts to enforce a national incomes policy.

The structure of pay

Systematic differences are found in the average earnings obtained in different regions, industries, and occupations. The average earnings prevailing in different regions of a country show a considerable range between the highest and the lowest, even when the same procedures for fixing rates apply everywhere. Much of the dispersion is due to differences in the localization of industry: if the relatively high-paying iron and steel industry, for instance, is concentrated in a particular region, then the average pay of the region will be raised to that extent. But regional differences also exist because work of the same kind frequently commands different rates of pay in different regions. Such differences are sometimes necessary to maintain the balance of payments between regions; they may also be in some measure a legacy of history and are likely to be reduced as communications improve and labour becomes more mobile. As noted above, this process of reduction has been expedited by trade union pressures.

Factors in pay variation

Average earnings also vary from industry to industry, and the considerable range that appears can again be attributed largely to differences in the composition of the labour force: an industry such as printing, which by the nature of its processes employs a high proportion of skilled workers, will on that account alone show higher average earnings than, say, the textile industry, which employs a higher proportion of the semiskilled. The similarity between the structure of earnings by industry in different countries—with printing, iron and steel, and engineering near the top, and textiles and food processing low down—is thus attributable to common processes requiring similar compositions of the labour force.

OCCUPATIONAL PAY THEORIES

This occupational structure, therefore, presents the main object of economic analysis. International comparisons show that the ranking order of the rates of pay prevailing in different occupations is similar in different countries, but that the range, whether between professional and manual occupations or, within the manual, between the skilled and unskilled, is much wider in economies at an early stage of development and diminishes in the course of development. These are the principal observations to be accounted for by any theory of the differences in the rates of pay that different kinds of work command. Several such theories have been propounded.

The narrowing gap between rates of pay

Status. One theory stresses the link between occupations and their status in the community, some having higher status than others. The community believes, according to this theory, that pay should correspond to status; and the rate of pay for each occupation is assigned to it by common consent, reflecting the place it occupies in the hierarchy of esteem. The implications are that the community's discretion is not as a rule subject to other factors such as the market forces of supply and demand and that, if people came to make less distinction of status between occupations, then the rates of pay for different jobs could be more nearly equal. Doubtless, many people do think in the way the theory supposes, feeling it anomalous, for example, when an occupation that is commonly

accorded a higher status than another ceases to command a higher rate of pay. But the correspondence between status and pay is ambiguous; it is not clear to what extent pay is made to fit the status and to what extent status follows from pay. Moreover, the occupational pay structures of different countries show more similarity than do their social values. Nor does the theory explain why the pay structure has generally become compressed in the course of development, and the ranking order sometimes inverted, as when some clerical occupations drop below some manual ones—changes that can otherwise be explained as the effect of extended education in increasing the relative supply of more qualified labour.

If the theory is not acceptable as an explanation of the pay structure as a whole, it does call attention to a factor that appears to affect parts of that structure. One of these parts is that of the higher administrative posts. It is generally accepted that any such post must carry a higher salary than any post below it in the chain of command; and when this chain is long, as it is in a big corporation, the salaries set for the posts in it, and the high level reached at the top, are to be accounted for by this principle.

Different rates of pay for men and women
The same theory also suggests a cause of prevailing differences between men's and women's rates of pay. Some women's work is different in kind from men's irrespective of the fact that it is done by women; and, where men and women both do work of the same description, some disabilities attaching to women as employees, in particular the likelihood that they will not stay in the job as long as men, may make them worth less to the employer. There are many jobs, however, in which these considerations do not apply and in which there is no difference in the productivity of men and women adequate to account for the actual difference between men's and women's rates. The difference seems attributable rather to customary attitudes and valuations—in particular, the assumption that women's productivity is lower in all jobs and the belief that pay should be proportioned to need (women workers generally needing less than the man who has a family to support). If such factors as these account for differences in pay between men and women where there is no corresponding difference in the work they do or the efficiency with which they do it, one may speculate that the same factors account for some part of the pay differential where the two kinds of job are distinct.

Unions and the rising pay of less-skilled workers
Power. A second theory lays its stress on power: the ways in which organized groups can protect and advance the pay of their members. Any group that restricts entry into its occupation can keep its labour relatively scarce and thereby support the rate of pay that that kind of labour commands. The discussion above of the economic effects of the trade union indicated the circumstances in which a trade union would be able to raise the relative pay of its members by the exercise of monopoly and bargaining power. The general increase in the pay of the less skilled relative to that of the skilled manual worker has been attributed in part at least to the increased unionization of the unskilled. Evidently, policies of organized groups will account for some part at least of the position of particular occupations in the pay structure. Power can also be endowed by management in the form of managerial authority, and at least a part of a hierarchy of pay within an organization is likely to be an imposed means of distinguishing and upholding the strata of the organization's internal power structure.

Value. A third theory treats the differences in pay for different jobs as corresponding to differences in their content or requirements. The simplest form of this theory was embodied in the labour theory of value, whether in the system of Adam Smith or of Karl Marx, by the assumption that different kinds of labour can be reduced to different quantities of "homogeneous labour time," and that rates of pay are then simply proportional to those quantities. Job evaluation, discussed above, purports to condense the varied requirements of each job to a single figure in a common scale in order that the ranking order of the rates of pay of the jobs may be brought into conformity with that of those figures. But the assumption that, if two articles are priced in the same currency, they must

contain quantities of a common substance is gratuitous. The impossibility of establishing the existence of such a substance and measuring the amount of it in any article drives both the labour theory of value and job evaluation into the circular argument of inferring the job content from the rate of pay and then explaining the rate of pay by the job content.

THE SUPPLY PRICE OF LABOUR

The foregoing directs attention to the supply price of labour to the job—the rate that must be paid if employers are to be able to attract and retain the quantity of labour that they wish to employ at that rate. Entry into an occupation generally imposes certain monetary costs; there may also be subjective costs, for example, in the effort of concentration required by preparation for examinations. The exercise of any occupation may be attended by disadvantages that require monetary compensation or may provide satisfactions and amenities that make workers willing to accept lower pay. For each occupation the various costs and benefits can be set off against the pay, and entrants will choose the one in which the prospective balance of advantage seems greatest. If more workers are to be attracted to and retained in a given occupation with unchanged conditions on the side of supply, the rate of pay in that occupation must be raised relative to others. An extension of supply will work to the opposite effect: for instance, if there is more public provision for secondary and tertiary education, and if rising standards of living enable more families to bear the costs of training, then a given number of workers will come to be available in a given occupation at a lower relative rate of pay. Here is to be found the reason for the occupational pay structure extending over a smaller range in developed than in poor countries and for the reduction in the margins for skill and the relative rate of pay for clerical work in the developed economies during the present century.

Education and the lowering pay of skilled workers

A number of considerations thus indicate that changes in the supply of labour influence its relative wage, although it is quite another thing to affirm the general theory of prices and assert that the rate of pay in any occupation tends to equality with the long-run supply price of labour to that occupation. The highly subjective nature of many of the costs and benefits involved in labour supply, and their dependence upon socially determined norms, strips the notion of a long-run supply price of any practical meaning. Nevertheless, in the absence of an extension of supply, a fall in the relative rate of pay of an occupation will bring a check to recruitment, followed by some withdrawal to other jobs of those already in the occupation. A rise in the relative rate of pay needs longer to take effect where proficiency takes long to acquire. Some types of proficiency may be limited by nature, and the rise in the rate of pay that follows on an extension of demand for them constitutes an economic rent—*i.e.,* a payment that is not required to maintain supply. In general, however, given time, the number of proficient workers available for follow a given occupation will be increased by a rise in the relative rate of pay it offers.

PRODUCTIVITY AND THE PRICE OF LABOUR

Orthodox economic theories. The complex character of labour as a commodity is nowhere more evident than in the relationship between pay and productivity. According to conventional economic theory, productivity should be the straightforward determinant of the employer's demand for labour. An employer who wishes to maximize profits will continue to recruit only up to the point at which the extra output gained from another worker equals the wage that worker is to be paid. This theory of marginal productivity lies at the heart of the orthodox economic theory of labour.

The theory of marginal productivity

The value of the theory, however, has come under question. Empirically minded economists note the profound difficulty of applying the theory when the productivity of individual labour in most organizations is unmeasurable and wage structures are internally connected. Aware of its weak analytic power, contemporary theorists in the orthodox tradition have suggested minor elaborations. Noting

a number of apparently discordant empirical and institutional features of the labour market, they have tried to bring them into the scope of formal economic analysis. Thus, taking the finding that local labour markets support a wide range of wage rates for a given grade of labour, search theory has tried to explain the phenomenon as a product of imperfections in information about available jobs and the consequent cost of searching. The same phenomenon is addressed by efficiency wage theories, which propose that the higher-paid occupants of a job grade are also achieving above-average productivity. Implicit contract theories, noting the considerable duration of most labour contracts, account for it as a necessary cost in the effort to overcome the difficulty of monitoring an employee's performance. That wages do not fall to levels that might, according to orthodox theory, eliminate unemployment is explained by insider–outsider theorists as a reflection of collusion between self-interested parties—in particular, those possessing jobs.

Such theorizing is promising, but it has shown relatively little explanatory power. It remains limited by a highly constraining view of the worker as an individual of purely rational motives and by an inability to grasp the significance of collective norms and behaviour in labour matters. It fails to explore the consequences of a world of imperfect product and labour markets, and its blindness to the open-ended character of the employment relationship prevents it from analyzing the significance of the varied institutional devices with which managers try to elicit productivity.

Empirical, multidisciplinary analysis. Something can be learned from the way in which employers manage productivity in practice. Employers pay great attention to internal pay structures, using job evaluation and other techniques to assure a stable and controlled structure of status within the work force. They give less detailed attention to what other employers are paying, so long as they keep the general level of pay increases broadly in line. They generally use specific incentive schemes more to generate an atmosphere of cooperation and flexibility than to make people work harder. Improvement in labour productivity comes overwhelmingly from technological change, requiring employees not to work harder but to work differently. The stress of such change to the employee is essentially temporary. It involves working with different workmates, facing the daunting challenge of learning a new skill, mourning for the lost opportunity to perform a skill of which one was once proud, and so on. Managers typically respond to the stress of meeting technological change with a temporary payment, although it may not seem temporary at the time. They may, for instance, introduce a new skill grade to match the new technique but remove it in a grade restructuring after a few years when memories of the upheaval have dimmed.

Employers are primarily concerned with unit costs, which involve both absolute wage levels and labour productivity. This concern arises from the pressures of the product market, which tend to override opportunities to pay what the labour market will bear. Employees, by contrast, think primarily of relative wages, especially very local relativities, and have only a fitful, vague, and temporary concern with their own productivity. They also place a relatively low priority on the opportunities offered by alternative wage levels in the labour market. It is in meeting this asymmetry of aspirations that the successful management of productivity lies, requiring constant tactical skill and personal attention on the part of employers.

Weakness of marginal-productivity theory

Such management implies the antithesis of marginal-productivity theory for two reasons. The first is that in a complex organization the productivity of the individual means nothing, and the productivity of the overall organization means everything. The second is that, in a world of imperfect markets, expecting prices to approach equilibrium in just one—the labour market—misses the important fact that competition is a total process, pursued on many fronts, such as design, marketing, and labour productivity—of which a competitive price for labour is only one.

Labour is by any standards an exceptional commodity.

The quality of it is molded by its social context, and it is able to influence the shape of its own markets. Only a multidisciplinary analytic approach can unravel this complexity. The competitive forces of the economists' marketplace do indeed have a substantial impact upon the price of labour, although through more than just the specific market for labour itself. The level at which these forces are most evident is at that of broad aggregates and long time spans.

Movement of the general level of pay

A wage is a price, and the rise of the general level of wages or rates of pay in the course of time has, to some extent, been part of the long-term rise in the general level of all prices—that is, of the cumulative depreciation of the purchasing power of money, largely attributable to increases in its quantity. In another way, however, the movements of rates of pay have been an independent cause of the rising trend of prices. At times those rates rose in common with prices under the pull of monetary demand (in times of inflation, during war, or in the rising phase of the trade cycle), but when the demand fell off they were resistant to cuts; and though they were cut somewhat, they commonly remained at a higher level than when the preceding rise began. A graph of product prices shows big falls as well as big rises, and sometimes a falling trend persisting for many years together; but a graph of money wage rates is more like a flight of steps. This characteristic of wage movements puts a floor under prices and provides a higher starting point for the next upward movement, so that the fluctuations of monetary demand impose a rising trend on prices. In addition, the analysis of cost inflation under full employment, noted above, has shown that when employers generally expect demand to be sustained, rises in pay may occur in the absence of excess demand, thereby initiating rises in prices; and it is possible that the same process may have played some part in the rising phase of the trade cycles of earlier years.

The level of real earnings

The rise of real earnings may be traced by comparing the movements of earnings in money with those of an index number of the prices of the articles on which pay is typically expended. Such comparisons indicate that between 1860 and 1960 the real earnings of manual workers rose fourfold in France, Germany, and the United Kingdom; more than fivefold in the United States; and more than sevenfold in Sweden. In considering the standard of living attendant on these movements, it is necessary also to take account of the prevailing reduction in the size of the family, the complex effects of urbanization on the amenities of life, the effects of changed techniques and deployment between occupations on the strains and satisfactions experienced in work, and the reduction of hours of work. The last element has been extensive: it appears that down to World War II the wage earners of the five countries mentioned, save the United States, gave up from a third to a half of the potential increase in annual purchasing power in favour of a shorter working week and longer vacations.

To the extent that real earnings are measured simply by the quantity of consumables that money earnings will buy, their rise has depended on three factors: productivity, or the output per worker in terms of his own product; the share of this product that accrues to the worker; and the rate of exchange between the worker's own product and the goods and services he buys. In the industrialized countries, the last factor has presented itself largely in the form of the terms of trade between manufactured products and primary products, especially foodstuffs: real earnings have risen faster or slower according as a representative consignment of manufacturers may be exchanged, at the prices of the day, for a greater or smaller quantity of foodstuffs and raw materials. There have also been variations from time to time in the second factor: the share of the product accruing to the worker. The effect of the last two factors, however, has been small in comparison with that of the first, the rise of productivity. The salient finding from the statistical record of the last hundred years is that real earnings per worker have risen very nearly in the same proportion as output per worker. (E.H.P.B./W.A.Br.)

ORGANIZED LABOUR: TRADE UNIONISM

Great Britain, Australia, and New Zealand

ORIGINS IN BRITAIN

British trade unionism has a long and continuous history. Medieval guilds, which regulated craft production, clearly differed in function from trade unions, in that guilds were combinations of both masters and workers while modern unions emerged to serve workers' interests alone. However, aspects of guild regulation—as in matters relating to apprenticeship—were incorporated into the objectives of early unionism, so that some continuity may be discerned between the decay of the one form of organization and the emergence of the other. Examples of the trade-union form of organization are hard to trace before the late 17th century; but during the following hundred years, combinations, as they were known to contemporaries, became widespread, emerging among groups of handicraft workers such as tailors, carpenters, and printers. Their emergence at this period was a result of the development of manufacturing and commerce on a capitalist basis. The number of handicraft workers within the economy was expanding, yet for such workers the prospect of making the transition from journeyman to master was diminishing. Both the rising demand for their labour and their emerging status as permanent employees were essential elements in this early development of labour organization. An additional factor, related to the rise of capitalism, was the progressive withdrawal of the state from wage regulation in particular and from labour-market intervention more generally. This was confirmed by the repeal, in 1813 and 1814, of legislation that had provided for the fixing of wages by justices and had stipulated apprenticeship requirements for entry into a trade. The state's withdrawal from labour-market regulation raised with some urgency the issue of the legality of trade unions. Under the Combination Acts of 1799 and 1800, a general prohibition had been placed upon them, in addition to the restraints imposed by the common law of conspiracy. Such a general prohibition now appeared anomalous and unjust, and it was indeed removed by legislation in 1824 and 1825. Common law impediments remained.

Craft orientation of early industrial unions
In the ensuing period, unions multiplied. As in the previous century, they were typically local in scope and craft in composition. Even in the emerging mechanized and factory-based sector, the relatively unsophisticated technology and managerial organization required the employment of skilled tradesmen, and these were assimilated into combinations based on the craft pattern of organization; engineers, boilermakers, and cotton spinners are examples. Yet, at this stage, the structure of unionism was still sufficiently fluid to permit widespread experimentation. During the 1830s there developed a movement toward "general unionism," directed both at establishing organization nationally and at drawing the various organized trades into alliance with one another. The pioneer in this movement was the cotton spinners' leader, John Doherty, but much of its impetus derived from Robert Owen, whose ideal of cooperative as against capitalist production found widespread support. The most ambitious Owenite union project was the Grand National Consolidated Trades Union of 1833–34, designed to embrace the whole of labour though in practice focused on London tailors and shoemakers. Inherently unstable, as were the other broad labour formations of the period, this union did not expire without leaving an enduring legacy. Six Dorsetshire agricultural labourers—the Tolpuddle Martyrs—were convicted and sentenced to transportation to Australia for swearing a secret oath in connection with the union. The union mounted a major campaign on their behalf, and this episode is still cherished by the modern labour movement as symbolic of its early struggle.

CRAFT UNIONISM IN THE 19TH CENTURY

British settlers brought their customs with them to Australia and New Zealand, and, accordingly, early unions

there corresponded closely to the pattern of the home country. The penal character of the settlements established in Australia from the late 18th century was hardly conducive to forming workers' combinations, but the transition from convict to free settlement brought the first signs of union activity. Local societies of craftsmen were operating in the 1830s and '40s, ostensibly for the purpose of providing friendly benefits for their members but in practice for trade purposes as well. Groups involved in these societies included printers, tailors, building craftsmen, and engineers. With the expansion of the economy from the 1850s, such groups formed the basis for permanent trade unions. The emerging pattern was one of craft unionism, in which Australian unions, like their counterparts in Britain, sought to restrict entry into and regulate working conditions within their respective trades. In Britain, during the middle decades of the century, a number of such unions developed their organization on a national basis. The most famous were the Amalgamated Society of Engineers and the Amalgamated Society of Carpenters and Joiners, constituted in 1851 and 1860, respectively. In Australia the main impetus to the national organization of trades came later, with the federation of the separate colonies in 1901.

In both countries, as unions consolidated their organization on independent and sectional lines, collaboration became a means of securing common legislative objectives rather than concerting industrial activity. This was classically the case with the British Trades Union Congress (TUC), an annual union assembly initiated in 1868 with a view to lobbying the legislature through a standing Parliamentary Committee. The model was followed in Australia, where, beginning in 1879, a number of Inter-colonial Trade Union Congresses were held, partly with a view to encouraging the formation of parliamentary committees in each of the self-governing colonies. Such political activity certainly achieved a further clarification of the unions' legal status. Legislation removing various remaining impediments was passed in Britain in 1871 and 1875; similar measures followed in all the Australian colonies between 1876 and 1902 and in New Zealand in 1878. Though the three societies differed in many respects, their broadly liberal character had, so far, proved accommodating to trade unionism. In Britain especially, unions had themselves contributed to this effect. As highly visible, stable, and professionally administered organizations, the national craft unions of the mid-19th century contrasted with the more secretive and volatile unions of the preceding era.

Formation of the Trades Union Congress

THE CRISIS OF THE 1890S: NEW UNIONS
AND POLITICAL ACTION

The late 19th century brought major labour upheavals that decisively influenced the further development of unionism in all three countries. In Britain, a tendency for unionism to expand beyond its narrow craft confines, apparent in the early 1870s, was curtailed during the depression of the mid-1880s. In the business upswing of 1888–92, the formation of new unions of less skilled workers was resumed, this time with the aid of socialist activists. The movement received an enormous stimulus through the victory of London dockers in their great strike of 1889, secured in the last resort by Australian financial support—a gesture from the New World to the Old. However, in 1890 employers in the maritime sector counterattacked against new unions of seamen and dockers, and the new union established in the gas industry also suffered major setbacks. Even certain craft unions experienced stronger resistance from employers, who were alarmed by the injection of a greater militancy into union behaviour at a time when they faced increased foreign competition in their established markets. Following a national lockout in 1897–98, the Amalgamated Society of Engineers was obliged to accept the introduction of new machinery and payment systems on employers' terms. In both the maritime and

engineering industries, employers had asserted their power by combining in national federations. Perhaps most serious of all for the unions, employer reaction spilled over into the courts, where a series of judicial rulings, culminating in the Taff Vale judgment of 1901, undermined the legislation of the 1870s.

A crisis in labour relations was also reached in Australia and New Zealand in 1890. From 1870, the craft character of unionism in those countries had also been modified by the emergence of national industrially based unions in the mining, shipping, and pastoral industries. The most notable examples in Australia were the Miners' Association and the Shearers' Union; these extended their organization to New Zealand, where union development closely paralleled that in Australia. Greater scale and militancy in labour organization, clearly apparent by the late 1880s, drew forth a corresponding response from employers, leading to major confrontations in the early 1890s. The first was the great maritime strike of 1890, involving seamen and wharf labourers in both Australia and New Zealand and also extending to shearers and coal miners. These new unions, however, had embarked on a trial of strength with associated employers at a time when the economy had turned against them, boom turning into prolonged depression. In conditions of heavy unemployment, the maritime strike was broken, and there followed further defeats for the shearers in 1891 and 1894 and for the miners in 1892.

Industrial defeats led unions to turn to politics with greater urgency than before. In New Zealand they gave their support to the Liberal Party, which won a historic victory in December 1890. The Liberals' social and economic reforms that followed attracted attention throughout the developed world, but they also may have delayed the emergence of labour as an independent political force, since the modern Labour Party emerged as late as 1916 and did not form a government for the first time until 1935. In Britain also the break with Liberalism came slowly, but interest in direct labour representation quickened in the 1890s, leading at the turn of the century to a political alliance between unions and moderate socialist groups. The Labour Party so created remained in the shadow of the Liberals until after World War I, but thereafter it developed rapidly to assume office for the first time in 1924. The link between the industrial defeats of the 1890s and direct union involvement in politics was most clearly manifest in Australia. By 1900, Labour parties had emerged in four of the colonies, consisting of affiliated trade unions and electorate branches. The federation of the colonies in the following year led to the formation of a national parliamentary party, and by the end of 1915 Labour governments were in office at the federal level and in five of the six states. Despite differences in timing, the experience of all three countries was remarkably similar, with enhanced union interest in politics from the 1890s leading to the formation of Labour parties and, ultimately, Labour governments. However, the outcomes of such political involvement, in regard to the unions' situation within the wider society, diverged widely between New Zealand and Australia on the one hand and Britain on the other.

COMPULSORY ARBITRATION AND UNION GROWTH IN AUSTRALASIA

To remedy their industrial weakness, unions in Australasia turned to the state and the law for support, through the installation of systems of compulsory arbitration that would oblige employers to deal with them. It was the Liberal government in New Zealand that enacted the first effective measure. The Industrial Conciliation and Arbitration Act of 1894 was drafted by that government's most radical member, William Pember Reeves, a socialist among liberals. Addressing the problem of employers' noncompliance with arbitration decisions, Reeves devised a system in which participation was voluntary for unions but compulsory for employers. A union that chose to register under the act could bring any employer before the Arbitration Court, whose awards had legal force.

Following the New Zealand legislation, compulsory arbitration was introduced in Australia at both the state and federal level. The major landmarks were the Acts of 1900 and 1901 in Western Australia and New South Wales, respectively, and the federal statute of 1904. The new system was not installed without a struggle; employer opposition was strong, and it was overborne only by a combination of political forces that included Liberals and the new Labour parties. The New Zealand experiment also attracted attention in Britain. Within the TUC, support came from weaker, newer unions that had not yet achieved employer recognition and saw compulsory arbitration as a means of enforcing it. The temporary operation of such a system in World War I did indeed have this effect, but at the turn of the century most unions were skeptical. Legally enforced collective agreements would entail closer involvement with the judiciary, and British judges were regarded as incapable of delivering impartial rulings on labour issues. Following the 1901 Taff Vale judgment, union support for the Labour Party developed rapidly, with a view to securing maximum freedom from judicial interference. In the 1906 Trade Disputes Act, British unions secured the legal immunities they desired, and the principle of legal abstention remained fundamental to the conduct of British labour relations to the 1970s.

In a different social setting, Australasian unions believed that compulsory arbitration would work to their advantage, and so it proved. In 1890 there was little to suggest that the propensity to unionize was exceptionally high in these countries, but 20 years later Australia was the most highly unionized country in the world, and union coverage had been greatly extended in New Zealand as well. Apart from a slight drop in the early 1920s, growth in union membership in Australia was virtually unchecked until 1927, the proportion of the work force organized rising from 9 to 47 percent. Compulsory arbitration explicitly recognized and protected unions, and under it even the weakest unions could force employers to have the pay and working conditions of their employees fixed by an arbitration court. This capacity drew in recruits, and in both countries growth was further encouraged by the practice of handing down arbitration awards that conferred preference in employment on union members. In the case of New Zealand, a 1936 amendment to the legislation of 1894 provided for compulsory union membership—a change that led to a dramatic increase in union coverage. In Australia a further crucial development came in 1907, with the Arbitration Court's judgment in the Harvester case. This ruling held that a living wage was a first charge upon industry, and it set a basic wage for unskilled labour at a level substantially higher than existing rates—an approach to wage determination that unions could certainly live with. Within both countries, however, the degree of dependence of unions upon legal support varied. Unions with a small or scattered membership (and there were many such) were almost wholly dependent; but for larger and more concentrated organizations, a real alternative existed in the shape of direct bargaining and strike action.

In the years immediately before and after World War I, that alternative found increasing support in unions of miners, railway men, and wharf workers, where, as in Britain, the syndicalist ideology of direct action had acquired some influence. Syndicalist rejection of parliamentary politics, and hostility to the state in all its forms, was given particular edge in the context of compulsory arbitration. In New Zealand a militant Federation of Labour developed in opposition to the arbitration system, and in 1912–13 a violent confrontation occurred in ports and mining towns, but the strikes were broken by employers (now mobilized in defense of arbitration), farmers, and the government. It was significant that the majority of unions valued their registration under the Arbitration Act too highly to affiliate with the Federation of Labour. In Australia, compulsory arbitration also survived an increased advocacy and practice of strike action. During and after the war the idea of the "One Big Union," which would unify existing organizations and maximize striking power, gained a certain currency. It seems to have delayed the emergence of an Australian counterpart to the TUC, toward which the intercolonial congresses of the previous

The Taff Vale judgment

The Harvester case in Australia

century had been moving. Eventually hopes of realizing the grander plan faded, and the Australian Council of Trade Unions (ACTU) was formed in 1927. Though some of the impetus behind the ACTU's emergence came from those who saw it as an instrument for the coordination of strike activity, in practice its survival owed much to the function it performed within the federal arbitration system in representing unions in basic wage and other national test cases.

UNION EXPANSION UNDER A VOLUNTARY SYSTEM

In Britain the broadening of unionism's membership base was underpinned by the spread of employer recognition and voluntary collective bargaining procedures, and it was the union leaders' faith in this process that encouraged them to believe that they could dispense with political and legal support. The engineers' defeat in 1898 did not lead to a withdrawal of employer recognition, and by this stage collective bargaining had spread beyond the crafts into coal mining and cotton manufacturing. However, unlike the craft, coal, and cotton unions, those of more recent origin still faced an uphill struggle. In the maritime, railway, and gas industries recognition was commonly denied, but the willingness of the new unions to recruit across occupational boundaries contributed to their survival. During the years after 1910 it was the unions constituted on a general or multioccupational basis that grew most rapidly. Of the three largest unions of the second half of the 20th century, two—the Transport and General Workers Union and the General and Municipal Workers Union—were direct descendants of new unions of 1889.

The "new unions" of the 1890s

Though union membership growth was a marked feature of the early 20th century in Britain, as in Australasia, its upward course was less steady and more vulnerable to shifts in the economic cycle. In the full-employment years of 1910–20 it was explosive, accompanied by an escalation of industrial militancy in mining, railways, docks, and elsewhere. As in the former colonies, such militancy was tinged with syndicalism. But growth was halted abruptly in 1920, with membership at 45 percent of the work force, and in conditions of heavy unemployment there followed a long decline into the early 1930s. Though unemployment checked growth in the other countries as well, the contraction in British union coverage, to 22.6 percent, was particularly severe. Despite the shrinking membership, industrial conflict took time to abate, as employers' efforts to force down wages were met with determined resistance. In 1921, with the creation of a General Council, the TUC had equipped itself to coordinate industrial action, and this power was put to the test in 1926 when a general strike was called in support of the Miners Federation. Conflict on this scale inevitably pitted unions against state, and it was this wider aspect of the dispute that in the end caused the TUC, committed as it was to constitutional modes of action, to call the strike off. Government, for its part, having established what it regarded as the boundaries of legitimate action and having confirmed them in legislation in 1927, was not inclined to intervene further to restrict union activity. Nor did employers move to de-recognize unions.

TRADE UNIONISM AFTER WORLD WAR II:
AN EROSION OF STRENGTH

In conditions of full employment and inflation following World War II, the respective industrial relations systems of both Britain and Australasia came under strain. In the case of compulsory arbitration, unions that had once clung to the system when they were weak now chafed at its restrictions when their strength was recovered. At an early stage there were confrontations involving traditionally militant mining and wharf unions. With the Cold War then at its height, Communist influence within such unions called forth drastic countermeasures by governments, and the 1949 coal strike and 1951 wharf strike, in Australia and New Zealand, respectively, were decisively defeated. As in the past, however, the majority of unions were not drawn into open opposition to arbitration. Nonetheless, though the "adventurist" phase of Communist-inspired militancy was over, more general tendencies toward direct

bargaining and strike activity persisted in both countries. Established as an alternative to industrial conflict, compulsory arbitration always faced in practice the problem of how to deal with strikes. A crisis was reached in Australia in the 1960s, when unions were fined for strikes with increasing frequency. The imprisonment of a union official in 1969, in an attempt to recover payment, led to a wave of protest and to the tacit abandonment of penal sanctions. The episode was revealing. It was the system's flexibility, its capacity to adapt to variations in the balance of industrial power over time and between different industries, that had contained the unions within it. Indeed, flexibility (and complexity) became such marked characteristics of the system that doubt grew as to its continued usefulness. In the 1980s the Australian government commissioned a complete review, yet the Hancock Report that emerged recommended no fundamental modification. Compulsory arbitration had been woven deeply into the fabric of national life in both countries, and in the process unions had been integrated more completely than in other democracies.

Crisis in the compulsory arbitration system

In postwar Britain, enhanced union power was widely blamed for inflation and for overmanning and disruption in industry. Between 1945 and 1951, when the Labour Party was in government and the wartime ban on strikes continued, integration between state and unions was unusually close. Government acted to break a series of dock strikes, without general union opposition, in a situation that closely paralleled that in Australasia. Through the 1950s and '60s, however, unions and government drifted into opposition. The wartime experiment in compulsory arbitration had struck no deep roots and was abandoned, while the return to purely voluntary bargaining was increasingly perceived as damaging in its economic consequences. Under full employment, shop steward organization spread rapidly through industry and was associated with a growing tendency toward unofficial, or "wildcat," strike activity. The voluntary institutions of British industrial relations appeared to be breaking down, and they were subjected to searching review by a Royal Commission on Trade Unions and Employers' Associations appointed in 1965. The largely voluntary remedies proposed by the commission did not satisfy governments, which were intent on urgent action. In 1969 a Labour government proposed legal restraints on unofficial strikers, enforceable by fines—a development even less welcome to British unions than to those in Australia. The proposals were withdrawn, but the successor Conservative government introduced a new legal code in the Industrial Relations Act of 1971, which included laws on unfair industrial practices and on legally binding agreements. These and various other provisions were to be enforced by a special Industrial Relations Court—in effect reversing the entire British tradition of legal abstention. Even then, unions refused to be contained within the tight legal framework that had been created, and this government was besieged by a renewed industrial militancy that not only rendered its legislation inoperable but also brought it to electoral defeat on the issue of the enforcement of statutory controls on wage bargaining.

In all three countries, profound shifts in the structure of the employed population during the later 20th century eroded the traditional membership base of unions. In following these shifts toward white-collar, female, and service-sector employment, unions endeavoured to match strides with the rapidly changing composition of the work force—just as, earlier in the century, they had broken through the divide separating skilled from unskilled manual labour. However, though their composition was modified profoundly, with greatly increased representation of white-collar and female employees, they could not keep pace. Union coverage of the work force in Britain recovered to its 1920 level in 1948, then surged forward in the 1970s to pass 50 percent for the first time. From a peak in 1979, however, it fell away. Closer integration with the state may have afforded Australasian unions better protection against the adverse consequences of structural change, but this is uncertain. Australian union coverage peaked at 60 percent in 1954; subsequent decline was checked in the early 1970s, but by the late 1980s cover-

Changing structure of the work force

age may have been as low as 42 percent. Higher levels of unemployment from the 1970s reinforced the trend, associated as they were with a rapid contraction of employment in union strongholds in manufacturing, mining, and the docks. In Britain this contraction was accelerated by a series of union defeats, the most drastic of which was inflicted upon the National Union of Mineworkers in the great strike of 1984–85. Legal restrictions on British unions, attempted in the 1970s, were reintroduced in the following decade. But if the political and industrial climate had turned more sharply against British than Australasian unions, the problem of adaptation to change remained a common one.   (J.C.Lo.)

The United States and Canada

ORIGINS OF CRAFT UNIONISM

Trade unionism in North America had its beginnings in a transition during the late 18th century from a mutualist/ dependent to a free wage-labour system. As journeymen artisans moved out of what has been called "economic clientage" to master craftsmen, they found their interests in conflict with those of their employers. Only through collective effort could workers enforce the list of "prices" they established for their work and defend their trades against cheap and diluted labour. The first identifiable labour strike dates from 1768, when journeymen tailors in New York City stopped work to resist a pay cut. Sustained labour organization began with the Federal Society of Journeymen Cordwainers (shoemakers) in Philadelphia in 1794. The first sign of a labour movement—that is, organizational activity exceeding the narrow sectional interests of particular crafts—appeared in Philadelphia, where the various craft bodies joined in 1827 to form the Mechanics' Union of Trade Societies. In Canada, these developments were slower to emerge: the first craft locals appeared in Montreal in 1827 and in Toronto in 1832, and the earliest city central came only in 1871, with the formation of the Toronto Trades Assembly. The first national union of locals in a single trade to survive, the National Typographical Union, was formed in 1852 in the United States. Like other national unions that followed, it chartered locals in Canada as well; this led to its renaming in 1869 as the International Typographical Union—a designation that became common in North American unionism.

National and international unions

Rooted as it was in the preindustrial trades, this early trade unionism did not lose its essential craft character with the onset of industrialization. Mule spinners, molders, machinists, and iron puddlers and rollers were employing new skills, and they functioned in a factory context, but they had much the same collective concerns as did traditional craftsmen and fitted readily into the emergent trade-union structure. On the railroads, too, the key jobs were defined as operating "crafts." Even with the quickening pace of industrialism, then, North American trade unionism in the 19th century was overwhelmingly a movement of skilled workers.

But job consciousness, powerful though it was, by no means constituted the sole, or even predominant, inspiration for collective activity. Historical research on working-class life has demonstrated that labour consciousness was a complex phenomenon, rooted in distinctive structures of culture, community, and ideology as well as in craft identity. American workers of the Jacksonian era adhered to a conception of artisan republicanism, which celebrated producerist values and the republican ideals of the American Revolution. Counter to this vision ran the corrosive impact of emergent industrial capitalism, which, in the view of the Philadelphia Workingmen's Party, created "invidious distinctions [and] unjust and unnatural inequalities" by dividing Americans into "two distinct classes, the rich and the poor." Beginning with workingmen's parties in the 1830s, a series of labour-reform movements fought a running battle for "equal rights." In the 1860s, this was the task of the National Labor Union and, after its decline, of the Knights of Labor. On their face, these reform movements seemed to cut athwart trade unionism, insofar as they aspired to the cooperative commonwealth rather than simply to a higher wage, appealed broadly to all "producers" rather than strictly to wage workers, and thought of themselves as broadly inclusive political and educational movements. But contemporaries saw no contradiction here: trade unions tended to workers' day-to-day needs, labour reform to their higher hopes. While the two were accepted as strands of a single labour movement, however, it was well understood that they were strands that had to be kept operationally apart.

During the 1880s, that functional separation began to break down. The international craft unions, having by now emerged as the dominant element in the trade-union structure, became less tolerant of challenges to their jurisdictions and internal lines of authority. For its part, despite a robust labour-reform rhetoric, the Knights of Labor began to act increasingly like a rival trade-union movement, carrying on strikes and organizing workers along industrial rather than craft lines. When the Knights rejected a proposal reaffirming the historic separation of trade-union and labour-reform functions, the alarmed internationals joined in December 1886 and formed the American Federation of Labor (AFL). The immediate aim was to drive the Knights from the industrial field, and, thanks largely to the Knights' own confusion and to employers' counterattacks, this was speedily accomplished. But more important in the long run was the permanent stamp that the AFL made on the American labour movement. This was partly institutional: the AFL legitimized the emergent trade-union structure that gave preeminence to the rule of the internationals. But equally significant was the enunciation of a guiding labour philosophy—"pure and simple" unionism—under the aegis of Samuel Gompers and his circle of Marxist trade unionists. Labour reform was thenceforth denied any further role in the struggle of American workers. The weapons in that struggle were to be defined as economic and not political; the participants would be strictly wage workers organized along occupational lines; and the objective of trade unionism became exclusively the incremental achievement of higher wages and better working conditions.

"Pure-and-simple" unionism

In Canada these American events had very considerable consequences. Given the sparse settlement and small industrial base, Canadian unions found it difficult to build a national structure of their own. An attempt initiated by the Toronto Trades Assembly in 1873 soon failed. It was also natural, given the colonial (after 1867, dominion) ties to Britain, for Canadian workers to look to English unions, and at least two groups—the carpenters and engineers—in fact built up sizable Canadian memberships after 1850. But the much more compelling links were to the United States, partly because labour markets in many skilled trades ignored the national boundaries and partly because the American unions were the readiest source of institutional assistance. By the end of the 1880s, as many as half the organized workers in Canada were in locals affiliated to internationals with headquarters in the United States. And it was this segment of Canadian labour that was mainly responsible for forming, parallel to the AFL, the Trades and Labor Congress (TLC) in 1886.

For some years, the TLC followed its own bent. The Knights of Labor had been highly successful in Canada, notably in Quebec. After virtually disappearing from the United States in the early 1890s, the Knights remained a considerable force in Canada, and, although strictly excluded from the AFL, were made welcome in the TLC. As late as 1901, moreover, its president was proposing that the Canadian branches break their links with the internationals, form their own national unions, and turn the TLC into a wholly Canadian movement. But in 1902 just the opposite transpired. The TLC expelled the Knights and adopted the AFL principle of opposition to dual unionism, which meant that the Canadian branches of the internationals gained a virtual monopoly on trade-union representation in the TLC. It became, in effect, the Canadian wing of the American movement. Responding to Canadian political conditions, the TLC was somewhat more flexible than the AFL on issues of independent labour politics and state intervention, but, on the whole, American pure-and-simple unionism exerted the commanding influence on Canadian unionism in these years.

Only in Quebec did a very different tradition assert itself. Here, following a lockout of boot and shoe workers in 1900, the Roman Catholic church stepped in and, in accordance with the papal encyclical *Rerum Novarum* (1891), encouraged the unionization of Quebec workers. The result was a vigorous French Catholic movement, the Confédération des Travailleurs Catholiques du Canada, which stands as a unique instance of confessional unionism in North America. Only after World War II did Quebec unionism shed its links to the church and evolve into a secular movement.

CHALLENGES TO PURE-AND-SIMPLE UNIONISM

The
Industrial
Workers of
the World

In the American West, pure-and-simple unionism was challenged in 1905 by the Industrial Workers of the World (IWW). The IWW had two sources. One was the socialist left wing, which had concluded that the AFL could not be captured and made over into the necessary trade-union base for socialist electoral politics. The second was a western brand of working-class radicalism forged by a decade of industrial war in the western mining states. The two groups proved incompatible, and the IWW, dominated by radicals from the Western Federation of Miners, drove out the socialists and committed itself to a syndicalist version of class war, in which political action was excluded. Struggle would centre on direct industrial action and ultimately on the revolutionary general strike, and out of that would emerge a workers' society organized on the basis of industrial unions. The IWW led a number of important strikes in the east between 1907 and 1913, but its main theatre of operations was among western workers, including Canadians, in metal mining, lumber, transportation, and agriculture. During World War I, however, the IWW was violently suppressed, and it never regained the organizational momentum of its peak years between 1914 and 1917.

The Canadian version of western syndicalism sprang into life in 1919, just as the IWW was expiring. This was the One Big Union (OBU), which had its roots in a postwar labour disaffection from conventional trade unionism that was especially pronounced in western Canada. Structured more along geographic than along the industrial-union lines of the IWW, the OBU had its moment of glory in the Winnipeg General Strike of 1919, and for a few years thereafter it virtually displaced the TLC as the dominant movement in the four western provinces. The OBU, despite its swift collapse, left behind a significant regional legacy: thereafter, the western provinces would persistently be the site of a more progressive, politically active brand of Canadian trade unionism.

The syndicalist challenge stemmed, to some degree, from the failing fortunes of pure-and-simple unionism in the early decades of the 20th century. The essence of that formulation had been to locate labour's struggle firmly in the industrial arena. But the struggle for collective bargaining proved to be much harder than Gompers and other trade unionists had anticipated. Where competitive pressures were severe enough, as in bituminous coal mining, not even the most innovative and determined of union efforts at market control proved sufficient—hence the collapse of the United Mine Workers of America (UMWA) in the 1920s. Elsewhere, as in the metal-fabricating industries, the problem was the speed of technological innovation and, in particular, the perfection of mass-production methods, which undercut the role of craft workers. Scientific management, moreover, demanded strict supervisory control over the workplace and hence posed a profound threat to customary patterns of workers' autonomy in the labour process (see above, *History of the organization of work*). When an effort to find common ground in the Murray Hill agreement (1900) between the International Association of Machinists and the National Metal Trades Association failed within a year, the die was cast: a quarter-century of bitter industrial warfare ensued. Labour's fortunes varied at different times and places, but the end result was unquestionably an arrested labour movement, with union penetration settling at roughly 10 percent of the nonagricultural labour force. As welfare capitalism took hold in the New Era of the 1920s, the more advanced sectors of

the industrial economy seemed quite beyond the reach of the AFL.

ESTABLISHMENT OF INDUSTRIAL UNIONISM

Progress
under the
New Deal

With the onset of the Great Depression in 1929, the balance of forces in the United States shifted dramatically. To begin with, national politics became more favourable to organized labour. Partly for ideological reasons, partly because of labour's increasing influence on the Democratic Party, Franklin Roosevelt's New Deal proved much more responsive to trade-union demands than had the Republican administrations of the post-World War I era. By now, moreover, key union leaders—most important, John L. Lewis of the UMWA and Sidney Hillman of the Amalgamated Clothing Workers of America—had defined what the labour movement most required from the state: protection of the rights of workers to organize and engage in collective bargaining. These rights were asserted in principle under Section 7(a) of the National Industrial Recovery Act (NIRA) of 1933 and then made thoroughly effective by passage of the National Labor Relations Act in 1935. More commonly known as the Wagner Act, the latter legislation prohibited employers from interfering with the right of workers to organize and from dominating the organizations they established. It also defined the procedures by which, through majority rule, workers selected their bargaining agents; required employers to bargain with such agents to the end of reaching contractual agreements; and set up, through the National Labor Relations Board, quasi-judicial mechanisms for enforcement of the law. American employers lost the enormous power advantages they had enjoyed in the struggle over collective bargaining, but in exchange the labour movement conceded the highly prized independence from the state that was a core element of pure-and-simple unionism. Under the Wagner Act, collective bargaining remained "free"—that is, the terms of agreements were not to be mandated by the state—but the framework itself came securely under the aegis of state regulation.

At the same time, the New Deal moved to mitigate the market pressures that had driven the antiunionism of American employers. The NIRA legislation, through codes of fair competition, was designed to enable industries to cartelize their depression-ridden markets. The exchange was entirely deliberate—granting representational rights to workers as a price for granting market controls to industry. As the basis of New Deal economic policy, this attempt at industrial stabilization lasted only two years, but the underlying linkage of labour rights and market benefits survived invalidation of the NIRA by the Supreme Court in 1935

The Wagner Act contained an explicit economic rationale: collective bargaining would generate the mass purchasing power essential for sustained economic growth. This, in turn, prefigured the Keynesian economic policy that, by managing demand, became the government's way of underwriting the New Deal's collective bargaining system after World War II. With federal macroeconomic policy (as specified by the Employment Act of 1946) responsible for maintaining long-term demand, and price competition firmly controlled by the restored oligopolistic structures of the major industries (or, as in the transportation and communications sectors, by direct state regulation), the market-driven basis for American antiunionism seemed to have run its course in the postwar era.

Collective
bargaining
and control
over the
work
process

Much the same could be said for the labour-process basis for antiunionism in the key mass-production sectors. By the 1930s, the Taylorist crisis over job control had passed; what remained at issue was no longer whether managers had the authority to control the labour process but only how they would exercise it. There were compelling reasons, almost systemic in nature, for the formalization of labour-relations policies. For example, where tasks were subdivided and precisely defined, job classification necessarily followed, and from that in turn came the principle of pay equity. Time-and-motion study—another pillar of Taylorist management—meant objective, testable standards for setting the pace of work. Corporate commitment to this formalized system was imperfect, however, and

broke down disastrously in the early years of the Great Depression. Rank-and-file fury over job insecurity and intolerable speedups, plus pressure from New Deal agencies and the labour movement, forced management's hand. Consequently, between 1933 and 1936—before collective bargaining actually began—all the key elements of the modern workplace regime fell more or less into place: specified, uniform rights for workers (beginning with seniority and pay equity); a formal procedure to adjudicate grievances arising from those rights; and a structure of shop-floor representation to implement the grievance procedure. Corporate employers would have much preferred to keep this regime under nonunion conditions. Indeed, it had taken shape in the course of their efforts to implant so-called employee representation plans (*i.e.,* company unions) that they had hoped would satisfy the requirements of New Deal labour policy. But when that strategy failed, managers were prepared to have their workplace regimes incorporated into contractual relationships with independent unions within the terms of the Wagner Act.

To fulfill its part in this process, the labour movement had first of all to adopt an industrial-union (*i.e.,* plantwide) structure appropriate to mass-production industry. The problem was that the AFL was committed to a craft structure and, under its constitutional rules, lacked the means to compel member unions to cede jurisdictions they held over craft workers in the mass-production sector to the emerging industrial unions. This impasse was broken only by a split within the AFL in 1935, leading to the formation of the rival Congress of Industrial Organizations (CIO) under the leadership of John L. Lewis. Even then, once the CIO unions scored their dramatic unionizing victories in rubber, auto, and steel of 1936 and 1937, a second condition had to be met: the CIO unions had to demonstrate their capacity to enforce the contractual provisions of workplace due process and discipline a turbulent rank and file. World War II brought this second phase to completion. Under close wartime regulation, institutional relations between the CIO and corporate industry were solidified, and, after a strike wave tested the parameters of this relationship in the immediate postwar period, there ensued a system of industrywide collective bargaining that endured for the next 40 years.

The industrial-union struggle spilled over from the United States into Canada. At the insistence of the AFL, the TLC expelled the Canadian branches of the CIO internationals in 1939. The next year these CIO unions joined the remnants of the All-Canadian Congress of Labour, which had formed in 1927 on the dual principles of industrial unionism and Canadian nationalism, to create the Canadian Congress of Labour (CCL) in affiliation with the American CIO. Only during World War II, however, did organizational realities begin to catch up with these superstructural developments. Although stirred by events south of the border, the Canadian movement did not experience a comparable surge of organization during the Great Depression. Only in February 1944 did the wartime administration of W.L. Mackenzie King issue Order in Council P.C. 1003, granting to Canadian workers collective-bargaining rights that American workers already enjoyed under the Wagner Act. The Canadian version, however, allowed for a greater degree of public intervention in the bargaining process. Investigative and cooling-off provisions in labour disputes were already a cornerstone of Canadian policy (going back to Mackenzie King's Industrial Disputes Investigative Act of 1907), and wartime conditions demanded a no-strike provision (linked to the mandatory inclusion of binding arbitration of grievances in union contracts), which likewise became a permanent feature of Canadian labour-relations law. During the war decade, the Canadian mass-production sector was rapidly organized by CIO unions.

By the early 1950s the organizational situation was similar on both sides of the border. In both countries, one-third of the nonagricultural labour force was unionized. In both countries, the industrial-union federations peaked at roughly two-thirds the size of their longer established craft rivals. At the onset of the Cold War, an internal crisis over Communist participation gripped the labour movements of both countries. Although somewhat differ-

The Congress of Industrial Organizations

ent in its details, the outcome was identical on both sides of the border—the expulsion of Communist-dominated unions in 1949 and 1950. And when the American unions settled their differences and merged into the AFL–CIO in 1955, the Canadian federations followed suit the next year by uniting in the Canadian Labour Congress (CLC). At that point, 70 percent of all Canadian unionists belonged to international unions with headquarters in the United States. The 1950s can be said to mark the apex of this historical tendency toward an integrated Canadian-American movement.

DECLINE AND DIVERGENCE

Beginning in the 1960s, the fortunes of the two movements diverged. In the United States, market pressures steadily eroded the postwar collective-bargaining system. In auto, steel, and clothing, the problem was intensifying foreign competition; in communications, trucking, railroads, and airlines, it was federal deregulation in the 1970s; and elsewhere, as in mining, retailing, and meat processing, a host of nonunionized domestic competitors entered the field. Meanwhile, a structural shift occurred toward a service economy, narrowing the established union base in the goods-producing sectors: production workers made up 30 percent of the nonagricultural U.S. labour force in 1950 but only 22 percent in 1976. The economic troubles that then set in—declining productivity and a slowing growth rate, inflation, the harsh recession of 1982—had a devastating impact on the American movement. Between 1975 and 1984, four million members were lost, and the unionized share of the labour force shrank from 28.9 percent to below 20 percent. If not for public-employee unions, which added two million members between 1956 and 1976, the U.S. labour movement would have found itself in an even more parlous state, as unionization in the private sector slipped to close to pre-New Deal levels.

Canada's economy was comparably hard hit in these years, yet unions north of the border fared far better. Indeed, they grew steadily after the mid-1960s, and, with 3.5 million members by the early 1980s, claimed over 40 percent of the Canadian labour force—more than twice the union density in the United States. How is this remarkable divergence to be explained?

The decline of the American movement occurred within an increasingly hostile political environment. In Canada, on the other hand, a changing party system enhanced labour's place in Canadian public life. In 1961, with the backing of Canadian labour, the New Democratic Party (NDP) was formed as a social-democratic rival to the Liberal and Progressive Conservative parties. As it made headway, the NDP changed the landscape of Canadian politics. For its part, Canadian organized labour, by abandoning the nonpartisanship espoused by the AFL–CIO, not only gained political muscle but also became a progressive force in the nation's public life. It assumed the mantle of what has been called "social unionism"—in stark contrast to the political marginalization of the AFL–CIO that followed the collapse of the Democratic New Deal coalition in the late 1960s.

Beginning with passage of the Taft-Hartley Act of 1947, which applied unfair-labour-practice provisions to unions and in a variety of ways weakened their economic and organizational power, labour law in the United States became steadily more burdensome to the labour movement. By contrast, Canadian federal and provincial law retained, and even deepened, its pro-union bias. Nor was there any Canadian counterpart to U.S. President Ronald Reagan's decision in 1981 to break a strike by federal air-traffic controllers—an act of enormous symbolic importance that legitimized the resurgence of antiunionism in corporate America. Antiunionism gained no such public legitimacy in Canada. Underlying this was a factor emphasized by the sociologist Seymour Martin Lipset: that collectivist values inhering in Canadian political culture granted the labour movement a legitimacy it never quite achieved in the more entrepreneurial nation south of the border.

As these divergences became more marked, the "international" character of the North American movement began to wane. Public-employee unionism—even more promi-

Economic pressures on unionized industries

nent a recent development in Canada than in the United States—would have sufficed in itself to push the Canadian movement in an independent direction, but Canadian branches in the private sector as well began to break loose, some by seeking greater autonomy within their international unions, but others—including those of communications workers, paper workers, woodworkers, and auto workers—by splitting off and becoming independent. A dwindling share of the Canadian movement—less than 35 percent by 1990—retained ties to the AFL-CIO. Two developments offered some prospect for reviving the integrationist bent of the North American movement: first, the creation of a common U.S.-Canadian economic market and, second, the deepening crisis in Canada over an independent Quebec. But, in the main, events of the 1970s and '80s merely underscored the very different dynamics that were driving the Canadian and American trade-union movements and that seemed to be carrying them farther apart along separate paths of national development.

(Da.B.)

Western Europe

CHARACTERISTICS OF THE CONTINENTAL LABOUR MOVEMENT

The history of unionism on the European continent differs significantly in several respects from that in Britain and the United States. First, industrial development came later and proceeded faster than in Britain, with plants and enterprises starting on a large scale and often using the most advanced technology. This disconnected European unions from medieval craft traditions and prevented the establishment of a system of craft unions representing only workers with a specific skill. Early attempts at craft unionism were soon absorbed into broad and encompassing industrial unions, which organized all workers in an industry or country regardless of skill and employment status. These unions represented primarily the interests of workers in large establishments who had no particular skills to defend and whose employers exercised firm control over the organization of work, or they represented workers in industries such as railways, mining, and electricity supply, in which labour relations were a matter of public interest and concern. Not being able to monopolize an indispensable skill and thereby realize their interests at the workplace and through the market alone, workers in such industries needed unions capable of mobilizing mass solidarity across occupational boundaries. As a consequence, western European union movements have usually formed strong national confederations capable of representing their affiliates in political bargaining with the government; maintained weak or nonexistent division between skilled and unskilled, and often between blue-collar and white-collar, members or affiliates; contained a small number of large, instead of a large number of small, individual unions; conducted comprehensive industrywide collective bargaining with a tendency to reduce or eliminate wage differentials by sector, employer, skill, or occupation; and pursued a universalistic social policy—on such issues as social insurance, health care, and occupational safety—that takes the place of enterprise- or group-specific "voluntary" regulations characteristically negotiated by more narrowly defined, sectional unions.

A second distinction of trade unionism in western Europe emerged in the area of managerial prerogative. Since many continental industries started at new sites and on a large scale, they were less burdened with a legacy of local management and craft autonomy than were British enterprises. Because of the more unitary and centralized organization of European firms, a distinction between management and labour and the right of management to manage were from the beginning more securely established, and shop-floor contestation between management and labour over the organization of the work process became much less central to European than to British and American industrial relations. Representing both unskilled and skilled workers in large establishments, western European industrial unions were never committed to defending job demarcations among skilled and between skilled and

unskilled workers. This enabled especially the more politically powerful union movements to accept managerial prerogative and high flexibility in internal labour markets. In fact, their lack of commitment to any specific division of labour on the shop floor later enabled European unions to support and promote comprehensive public and private labour-market policies of general upgrading of skills and jobs. And while effective centralized control over the shop floor was ceded to management from the beginning, that control was later available to share with politically powerful unions if and when these were willing to seek legislation on "industrial democracy." "Cooperative" union participation in management then became possible, because industrial unions had no history of resisting large-scale organization as such, were not beholden to any particular group of workers, and had no principal interest in curtailing firms' internal flexibility.

A third defining characteristic of trade-union history in western Europe is in the area of political power. Unable to afford the laissez-faire liberalism of Victorian Britain, European states early on took an active role in the regulation of labour markets, often siding with capital in support of rapid accumulation. At a time when the doctrines of voluntarism and state abstention became established in British industrial relations, unions were regarded by European ruling elites as a threat to both national unity and economic progress. In these circumstances, "pure-and-simple" unionism was impossible. European unions had little choice but to define themselves as political movements—at least until conditions for independent, economic unionism had been created—and in fact they typically start out as industrial arms of political parties, usually socialist or Roman Catholic. Where political unionism was of the Roman Catholic kind, it aimed at establishing an autonomous space for cooperative industrial self-governance of workers and employers, free from interference by the modern nation-state. Where the guiding political doctrine was Socialist or, after 1917, Communist, the objective was to gain control over the state in order to use its growing interventionist capacities for fundamental social transformation in the interest of workers. Finally, where political unionism was syndicalist or anarchist, its ultimate goal was to replace the state with a political organization based on the workplace and on relations between associated producers.

Just as craft unionism gives rise to fragmentation by occupation, so political unionism may breed fragmentation along party lines, and by the end of the 19th century almost all continental European union movements outside Scandinavia were ideologically divided. In order to overcome these divisions, unions had to extricate themselves from the control of allied political parties, and European industrial-political unionism became most powerful where unions managed to escape political division, overcome it to form unified organizations, or coordinate their policies. Where organizational unity was accomplished, it enabled political unionism to become an independent economic and political force, continuing universalist traditions of comprehensive social reform without being subservient to any particular party or government strategy. Especially in northern and northwestern Europe, unions became established participants in national politics, functioning in a wide variety of policy areas as recognized quasi-public or para-governmental intermediary institutions.

FROM WORLD WAR I TO 1968: THE INSTITUTIONALIZATION OF UNIONS AND COLLECTIVE BARGAINING

By the early 20th century western European unions were making slow but steady progress toward expanding their membership, extending the range of collective bargaining, consolidating their organizations, and winning legal and political recognition. The breakthrough, however, came with World War I. Wartime mobilization brought tight labour markets, rapid expansion of mass production, long working days, hazardous working conditions in arms and ammunition factories, and soaring profits for employers. It also ushered in state intervention and economic planning on an unprecedented scale. As the war dragged on, national elites found themselves compelled to include

labour leaders in the governance of the war economy as managers of rising shop-floor discontent. Typically, union cooperation was gained in exchange for promises of democratization, union recognition, and redress of social inequities after the war.

Ironically, the position of moderate union leaders in national war coalitions was strengthened by objection among workers to the war and to the sacrifices demanded of them. All over Europe, autonomous movements of shop-floor workers' councils emerged, continuing labour's prewar tradition of pacifism and internationalism. Workers' councils not only opposed the governments that organized the war and the employers that profited from it but they also rejected the leadership of collaborationist unions and social-democratic political parties. Rather than parliamentary social democracy, their objective was a syndicalist political order founded on and controlled by councils of industrial workers. Especially toward the end of the war, council movements succeeded in organizing major strikes in a number of countries, and in Russia the Bolsheviks overthrew the tsar with a program of soviet (that is, "council") democracy (see below *Eastern Europe*). All of this enabled moderate union leaders to extract more promises and commitments from governments, military leaders, and employers for the time after the war.

Faced with overexpanded economies, huge national debts, a radicalized and assertive working class, and the threat of revolutionary internationalism inspired and supported by the Soviet Union, employers and political elites after 1918 were eager to close ranks with the moderate labour leaders who had assumed quasi-governmental responsibility during the war. In country after country, unions obtained major concessions, such as universal suffrage and parliamentary democracy, the right to strike, legal support of union organization and industrywide collective bargaining, the extension of industrial agreements to nonunionized firms and sectors, the eight-hour working day, a wide range of social benefits, joint councils of unions and employers to oversee key industries, and works councils to represent workers at the workplace. Often these were conceded as elements of comprehensive social pacts—like the Stinnes-Legien Agreement in Germany—that were negotiated between national organizations of capital and labour and underwritten by the government, apparently foreshadowing a continuing role of unions in the governance of national economies.

In most European countries, the bulk of the concessions made in the immediate aftermath of the war were withdrawn in subsequent years. Increasingly, the stabilization of western Europe's war-torn economies came to be perceived as possible only at the expense of workers and unions, with the fight against inflation seeming to require wage cuts, longer hours, curtailment of union rights, sharp reductions in public spending, and the resulting high unemployment. As domestic conflicts intensified, the political right found confirmed its old doubts about the compatibility of social order and national unity with democracy and free trade unions, and even the moderate left came again to question the compatibility of democracy and full employment with capitalism. The Great Depression of the early 1930s, in particular, brought large-scale unemployment and made deep inroads in the organizational strength and political influence of unions, in many countries abolishing the fragile postwar gains in the institutionalization of union rights and collective bargaining.

By the end of the 1920s at the latest, national political systems in Europe began to drift sharply apart. First in Italy and most dramatically in Germany, Fascist or conservative-authoritarian regimes either outlawed unions altogether—often driving their leaders from their countries, incarcerating them, or assassinating them—or turned them into appendages of an ever-more powerful state apparatus. Authoritarian responses to class conflict and economic crisis were encouraged by an international environment that seemed to offer little opportunity for shared economic growth and few if any alternatives to nationalist protection and preparation for renewed military hostilities.

In Sweden, on the other hand, the electoral victory of the Social Democrats in 1932 paved the way for the first suc-

cessful attempt to achieve full employment by Keynesian means under political democracy and free collective bargaining within a capitalist economy. After intense industrial and social conflict in the 1920s, the Social Democrats were able to unite their country behind a platform of state-led expansion, an extensive social-welfare policy, social equality, and institutionalized autonomy for responsible, centralized, and comprehensive collective bargaining. In 1938, the peak associations of business and labour concluded the Saltsjöbaden Agreement, in which, while affirming the rights of unions to strike and of employers to lock out in retaliation, they pledged to use these measures only as a last resort and in consideration of their effect on third parties. Swedish unions, having moved into a secure position of industrial strength in which their actions inevitably affected the performance of the national economy, accepted responsibility for economic growth and monetary stability in exchange for a number of concessions: a complementary social and labour-market policy; the cooperation of employers in a reduction of pay differentials; progressive taxation; expansion of employment in the public sector; and equal participation of women in the work force. Given such economic and political strength, Swedish unions were prepared to accept employers' claims to an almost unlimited right to manage. As World War II drew closer, therefore, Germany and Sweden represented opposite ends of a wide spectrum of western European politics and industrial relations.

It was only after 1945, under the leadership of the two victorious democracies, the United States and Britain, that unions and collective bargaining became firmly established throughout western Europe. In some countries, business and traditional elites were discredited by their collaboration with Fascist regimes or the German occupation. In others, joint resistance during the war had laid the ground for close postwar cooperation. Everywhere, the presence of Soviet Communism as an apparent alternative to capitalism seemed to make it imperative to include moderate labour movements in the reconstruction. And not least, the United States, as the architect of a system of free trade intended to be immune against the nationalism of the interwar years, needed to ensure that competing economies were saddled with the same social costs that it had incurred under the New Deal.

Modern western Europe thus came to be built on a "historical compromise" between capital and labour. Among the concessions gained by the latter were a firm commitment to parliamentary democracy; a welfare state establishing a basic floor of income and services for all citizens; a commitment of governments, of whatever political complexion, to an active full-employment policy; and the right of unions to free collective bargaining. In return, moderate labour movements pledged to pursue political reform only by constitutional means, renouncing in particular the use of the strike for political purposes; tolerated private property in the means of production; accepted a free-market economy with little or no public intervention in price formation; and agreed in principle to observe the right of management to manage. By the end of the 1950s at the latest, most European unions had, explicitly or implicitly, come to accept the terms of this bargain.

This second postwar settlement marked the beginning of the longest uninterrupted period of peace and prosperity in European history. Embedded in an international free-trade regime guaranteed and dominated by the United States, it helped accelerate the spread from America to Europe of "Fordist" modes of production and accumulation: the mass manufacture of standardized consumer durables in factories that used Taylorist methods of work organization and were operated by large, vertically integrated, and increasingly multinational corporations. By helping to expand and maintain the purchasing power of mass consumers, European unions also played an important part in the stabilization of economic growth. Moreover, by concentrating their activities on macroeconomic wage bargaining and redistributive social policies at the national level, political-industrial unions left managers the freedom to introduce new technologies and to rationalize the labour process in pursuit of higher productivity and profitability.

[margin notes]

Syndicalism

Collective bargaining in Sweden

The "historical compromise"

An inherent problem of the post-World War II settlement was that, with governments guaranteeing full employment and free collective bargaining, inflation could be contained only if unions resisted using their artificially increased bargaining power to win wage gains in excess of productivity increases. This required, at the minimum, effective control of national unions over the shop floor. While European industrial unions were much more successful in this than their British counterparts, by the end of the 1960s even their hold on their members began to slip. In part this was caused by a general rise in inflation imported from the United States. When unions continued to exercise wage restraint in increasingly overheated national economies, a new generation of workers that had not lived through the Great Depression and had never experienced unemployment turned against their leaders. All over Europe, massive waves of unofficial strikes occurred in 1968 and 1969, organized from the shop floor in defiance of national union policy and throwing moderate "income policies" into disarray. More subtle factors also contributed to this outbreak. By concentrating on macroeconomic matters during a period of aggressive rationalization and fast productivity growth, industrial unions had left workers with little protection at the workplace. Growing discontent with an ever more perfect Taylorist organization of work, workers found no official representation in an industrial-relations system that accepted managerial prerogative in the workplace in exchange for the recognition and political status of unions, full employment, growing wages, and a comprehensive welfare state. Remarkably, such discontent emerged strongly even in countries, such as Italy and France, where unions were weak and the shop floor was ruled by employer paternalism, and Germany and Sweden, where union distance from the "qualitative" issues of the workplace was part of a general union strategy of economywide solidarity and egalitarianism.

The strike wave of 1968–69

During the 1960s it had come to be widely believed in Europe that worker militancy was a matter of the past and that strikes in particular were withering away. This made the shock of 1968 and '69 all the more profound, and in the immediate aftermath employers and national governments accepted high wage increases and inflation rates in order to avoid further confrontations with workers. This lasted well into 1973 and 1974, the years of the first oil crisis, when governments continued to assign high priority to full employment without touching unions' right to free collective bargaining. Instead, economic stabilization was sought by bringing unions still further into the centre of policy making, increasing rather than curtailing their power and responsibility and helping them strengthen their organizations so that national union leaders could manage shop-floor discontent more effectively. This brought about a new political configuration that came to be known as "neocorporatism."

Essentially a tripartite social contract involving government, business, and labour, neocorporatism sought to restore full employment through moderate wage demands (often entailing losses in real wages and distributive position), in return for which unions were granted influence over policies relating to subjects such as unemployment insurance, employment protection, early retirement, working hours, old-age pensions, health insurance, housing, taxation, public-sector employment, vocational training, regional aid, and subsidies to declining industries. In addition, governments and employers agreed to a variety of means to help industrial unions strengthen their workplace organizations so they could better absorb worker discontent. One important means was legislation on industrial democracy. "Codetermination," as it was called in Germany and Sweden, provided workers with quasi-constitutionalized shop-floor representation on nonwage matters, such as work organization, that industrial unions had been unable or unwilling to address before 1968. Thus, in order to prevent a return of the representation gap of the 1960s and channel the energies of workplace unionists into economically innocuous activities, governments in a number of countries allowed industrial democracy to make significant inroads into managerial discretion. For this and other reasons, neocorporatism increasingly alienated European employers, but unions, backed by and working through the new or expanded institutions of industrial democracy, often succeeded in increasing their membership density during the 1970s.

Industrial democracy, or "codetermination"

The second oil shock in 1979 heralded fundamental changes in European economic policy and industrial relations. Faced with persistently high unemployment, an increasingly integrated world capital market and a rapid loss of competitive position to Japan, European governments gradually abandoned their attempts at bargained national accommodation with organized labour and gave preference to supply-side policies of competitive restructuring. An important factor in this restructuring was the advance of microelectronic technology. Unlike the dedicated technology of the Fordist period, microelectronics allowed for a variety of alternative, "flexible" ways of organizing production in response to different product strategies, local organizational structures and cultures, and available work skills. For unions to play a role in the reorganization of productive relations that was made possible (and necessary) by the new technologies, they had to decentralize their organizational and political capacities and create a strong union presence in the workplace.

Other factors also militated toward the decentralization of unions and industrial relations. As the work force became increasingly heterogenous, its interests were less easily subsumed under the blue-collar egalitarianism that had dominated union policies since the interwar and immediate postwar years. In particular, during the 1960s and '70s pay differentials had been reduced to the point where many skilled and white-collar workers were no longer willing to be represented by comprehensive, "solidaristic" collective bargaining. Class-based solidarity was further attenuated by growing employment in the public sector—often under privileged conditions that in the leaner 1980s were perceived by private-sector workers as coming at their expense. As a result, national unions found it more difficult to unite their members behind common demands. Where centralized wage bargaining did not actually break up—as it did in Sweden—union leaders came under pressure to give groups inside their organizations greater freedom to express and pursue their special interests.

During the 1980s most western European unions came to realize that the survival of the high-wage and high-welfare economies that they had been so instrumental in creating depended less on political bargains with the government and national employers' associations than on participating in this restructuring toward a flexible, highly skilled, innovative economy capable of producing customized and quality-competitive goods and services. This seemed to require cooperative workplace relations, flexible internal labour markets, extensive training and retraining of workers, and a fundamental reorganization of work. This last involved a blurring of the distinction between conception and execution or between indirect and direct, nonmanual and manual, and managerial and nonmanagerial work; decentralization of decision making; flatter hierarchies; and broader and overlapping job descriptions and skill profiles.

Adaptation to the changing workplace

Never having depended for their strength on job control, European unions found it easier to adapt to the "post-Fordist" forms of industrial organization than did their British or American counterparts. Still, adaptation required that unions decentralize their organizations and insert themselves into the workplace in a way that jeopardized neither productive cooperation nor their own independence. For this, industrial unions that could avail themselves of established systems of industrial democracy and codetermination seem to have been particularly well placed. Indeed, German and Scandinavian unions in particular may actually have contributed to the quality-competitive restructuring of their economies by, on the one hand, foreclosing employers' options of hiring low-wage and low-skill labour and, on the other hand, exerting pressures and creating opportunities at the workplace for the de-Taylorization of work organization and the general upgrading of production. Especially important in this con-

text were the unions' roles in labour-market policy and vocational training.

By adjusting to the requirements of productive flexibility at the workplace, then, most Scandinavian unions increased their membership density, while Belgian, German, and in part Italian unions maintained their strength. In France, Spain, and to an extent The Netherlands and Austria, on the other hand, unions were left behind by rapid industrial modernization and went into precipitous decline. (W.St.)

Eastern Europe

Trade unionism in Russia and other parts of eastern Europe developed in close relationship with political parties, usually revolutionary parties. Because the autocratic Russian state prohibited public organization of any sort, especially trade unions, autonomous workers' movements often shared common interests with revolutionary parties and tended to cooperate with them. Moreover, revolutionary Marxist parties grew simultaneously with an industrialized, urban labour force, so that political ideas—especially revolution and Socialism—helped to give definition to workplace struggle. Russian and Polish labour movements will serve as examples here.

RUSSIA

The earliest Russian labour organizations emerged among artisans in the form of legal guilds, which were not autonomous or spontaneous institutions but rather subject Mutual-aid to close state supervision. Late in the 19th century, these societies were joined by mutual-aid societies, which spread among the more skilled and literate craftsmen in capital cities and among Jewish artisans in the western part of the empire. Particularly among the latter, such societies sometimes evolved into illegal organizations for struggle with employers, but by and large their function was to provide mutual support and cultural self-help. The earliest mutual-aid societies were begun by printers in Warsaw (1814), Riga (1816), and Odessa (1816), but their real expansion came in the late 1880s and the 1890s. Meanwhile, the population of factory workers grew outside of the artisanal tradition, finding recruits among peasants and children of hereditary factory workers in state-owned military enterprises. Traditions of solidarity among factory workers were based on ties with fellow countrymen and on informal collective living arrangements called artels.

The growth of industry in the late 19th and early 20th centuries gave rise to a factory proletariat and to labour unrest, but government repression prevented intermittent strikes from leading to permanent forms of organization. Agitators from Marxist Social-Democratic groups attempted to organize strikers, but they were hampered by frequent arrest and imprisonment and by the reluctance of workers to entrust their struggle to the hands of outside intellectuals. In 1901, however, the Russian government embarked on a unique experiment and organized its own police-supervised unions to channel worker protest and preserve loyalty to the tsarist regime. Led by the chief of security police in Moscow, Sergey Vasilyevich Zubatov, such unions quickly emerged primarily among skilled factory workers in Moscow, St. Petersburg, Odessa, Vilnius, and Minsk. While the experiment soon lost favour with the government, it gave workers new experience with collective bargaining and grievance procedures, and it led to their demands for the right to choose shop-floor representatives and to strike.

The unrest that led to the Russian Revolution of 1905 grew out of this movement among factory workers, and in October of that year the tsar conceded to workers the right to organize trade unions. From their foundations in mutual-aid societies, police unions, and the independent strike councils (soviets) that had emerged during the revolution, new trade unions multiplied in October and November of 1905. In St. Petersburg, 30,000 workers joined 41 unions in just six weeks. In Moscow, 56 unions were created in this period, embracing about 25,000 workers. In both cities, tradesmen employed by small shops were the first to organize; metalworkers and textile workers, employed primarily in large plants, were slower to join unions, in part because their individual factories were big enough to offer by themselves the advantages of organization and solidarity.

The wave of union organizing continued into 1906 and 1907 with the publication of the Temporary Laws of March 4, 1906, legalizing the formation of public organizations. Union activists attempted to organize nationally, but before an all-Russia trade-union congress could take place, the union movement succumbed to a wave of reaction set off by the dissolution of the second state Duma (parliament) in June 1907. Police found unions in violation of some regulation or another (organizing strikes remained illegal, for example) and ordered them closed. The resulting precarious legal status of unions frightened prospective members, and union fortunes waned. Between 1907 and 1909, police closed 350 unions and arrested many of the most important labour leaders. By 1910, union membership had fallen to 60,000, compared to 250,000 members in January 1907. Beyond these legal members, there remained, in the underground or in exile, dedicated cadres of Social-Democratic activists who would become important leaders when unions' fortunes revived.

The Temporary Laws

Economic recession and political repression combined to depress trade-union activity until 1912. Those unions that remained legal could offer little to their members besides cultural activities and fellowship; collective bargaining, strikes, political activity, and intercity contact were all forbidden. During this period, differences between the approaches of Menshevism and Bolshevism, the two wings of the Russian Social-Democratic Workers' Party, became more pronounced. Mensheviks believed in service to the working class and focused on consumer cooperatives, schools, libraries, and clubs. Bolsheviks tended to engage in political and strike activity, trying to force a revolutionary situation. When union activism revived in 1912, unionists agitated for legal shop-floor representatives and collective labour contracts. Strikes increased in the period 1912–14 but remained outside the union sphere. Modest gains in labour legislation gave encouragement to a reformist wing of the union movement, but continued government harassment forced many activists to adopt a more revolutionary ideology.

World War I propelled hundreds of thousands of new workers—women, youths, and peasants—into Russian factories, diluting the old skilled cadres and creating new pressures on work culture. As a result, when the Russian Revolution of 1917 brought an immediate freedom to organize, trade unions had to compete as centres of organization with less cumbersome factory committees and urban soviets of workers' deputies. The main concerns of factory committees were local grievances, representing their factory to larger bodies, and adjudicating disputes among workers themselves, but, as trade unions failed to organize quickly enough to deal with problems of wages, hours, control, and regulation, factory committees began to join in citywide conferences to deal with many of these problems. Simultaneously, unions formed administrative structures, recruited members, and began to coordinate economic bargaining with employers. By the end of 1917, more than 2,000 unions had formed in Russia, with a reported membership of 2.7 million workers.

When the Bolsheviks came to power in November 1917 (October 1917, Old Style), much of Russian industry was at a standstill. Workers in many idle factories assumed the responsibility of restarting the plants, usually through their factory committees, but gradually, between 1918 and 1920, central and local government agencies took over. Most trade-union leaders agreed that, under Socialism, the primary task of unions was to facilitate production and that workers' interests were now identical to state employers' interests. Trade unions assumed more state functions, serving as military recruiting offices, centres of supply, providers of social services, and judicial organs. A minority of independent union leaders argued that the interests of workers and managers would always conflict, even under socialized industry, and that the task of unions was to defend workers first. A syndicalist minority within the Communist Party (as the Bolsheviks were renamed

Changes under Bolshevism

in 1918) believed that independent trade unions should manage the state economy. By 1921 a compromise was reached, pressured by widespread factory discontent: trade unions were thenceforth to have a "dual function" of helping to raise productivity while guaranteeing workers' legitimate rights against overbearing managers. As a "transmission belt" between the Party and the working rank and file, they would serve as a "school for Communism" and teach workers that their interests were identical with those of the state.

During the 1920s trade unions worked closely with state agencies in setting wages, providing unemployment relief and social services, and raising productivity. With the rapid industrialization drive of 1928–32, they became little more than administrative cogs of decreasing relevance to the interests of workers on the factory floor.

POLAND

Poland regained statehood in 1918, and a divided trade-union movement united. Trade unions had first developed in Galicia, in Austrian Poland, in the 1870s, where unions were legal. German trade unions had organized Silesian workers in the western part of German Poland, and in Russian Poland, as in Russia, unions were illegal. With independence, local unions combined into a powerful movement under the general influence of the moderate Polish Socialist Party, although the union movement maintained an official policy of party neutrality. Another group of Christian trade unions organized separately.

Poland in the early 20th century was still an agrarian country, with 61 percent of the population engaged in agriculture in 1931. Moreover, under a severe economic crisis after 1918, the labour force was very fluid, with workers moving in and out of industry. Union structure was based not on skill but on industry, and even unemployed workers were incorporated. The biggest unions, like the railway workers' union, supported extensive cultural activities, including clubs, libraries, and a secondary boarding school. Union membership in the 1930s fluctuated between 900,000 and 950,000 in spite of efforts by the government under Józef Piłsudski to split and weaken union solidarity. This figure represented about 18 percent of the working class of five million, including agricultural labourers and domestic servants.

Under the Communist government of Poland, the working class grew rapidly between 1947 and 1958. At the same time, trade unions became interlocked with management and government organs, losing their independent function. Wages were set centrally, and unions were relegated to administering social-welfare activities within the workplace. Even here, as the Polish economy began to decline in the late 1970s, unions faced challenges when they were unable to deliver these services, such as housing and holidays. At the same time, a shift in the social composition of the Polish working class created a less docile union membership. By 1972, only one-third of economically active Poles worked in agriculture; new recruits to industry came predominantly from proletarian backgrounds, and these were relatively young. The rapid mobility from blue-collar to white-collar jobs characteristic of Poland's earlier Communist years had now slowed. These structural characteristics, combined with economic stagnation and the inability of trade unions to respond, produced a wave of strikes in 1980 and the rise of new trade unions to challenge the old. To settle the strikes, the Polish government in August 1980 agreed to recognize new, self-governing trade unions, authentic representatives of the working class whose task would be to defend the social and material interests of workers. Within weeks, new independent locals had federated into a national independent union, named Solidarity. Old trade unions were simultaneously reconstructed to become more independent from the state, but their membership plummeted from 12 million to 4 million by the end of 1980. Solidarity was declared illegal in December 1981, so that trade unions continued to be more fragmented than before 1980, but this pluralistic trend contributed to the revival of Solidarity and the defeat of the Polish Communist Party in elections in the summer of 1989.   (D.P.K.)

Labour challenges under Communism

Japan

After Japan's surrender in 1945, Allied occupation reforms spurred a spectacular spread of independent trade unions, which had been eliminated during wartime. Until it was halted in 1949–50 by sharp deflation, revision of labour laws, and a purge of leftists, unionism enlisted 6 million members—almost half of all workers. Unions resumed steady growth after 1955 as industrial employment leaped upward with Japan's economic "miracle." Organized labour peaked in 1975 at 12.6 million members, one-third of all eligible workers, becoming the third largest movement among the industrialized democracies. As economic expansion slowed following the 1973–74 oil crisis and subsequent industrial restructuring toward hard-to-unionize services, union membership leveled off to one of every four workers.

Backed by new constitutional rights to organize, bargain, and strike, in sharp contrast to prewar years, Japanese unions made notable achievements as they increasingly emphasized industrial activity. Genuine union-management negotiations and wide-ranging joint consultation at enterprise, industrial, and national levels became well institutionalized. Also established was comprehensive legislation for labour standards and social security. Unions provided the principal support for such "progressive" political parties as the Socialists, Democratic Socialists, and Communists, in opposition to the conservative Liberal-Democrats, who reigned continuously after 1948. However, unions were faulted for severe ideological disunity, undue employer influence, and a narrow focus on their members' interests to the neglect of unorganized workers and the wider society.

A chief feature of Japanese unionism is its decentralized "enterprise-level" structure. Numbering more than 70,000, most basic union organizations form inside, not across, large-scale private enterprises and government agencies. Democratically run, well-financed, and self-staffed, the typical enterprise union actively represents only workers "permanently" employed in the firm—blue- and white-collar together and also foremen. This rank-and-file choice reflects the influence of fundamental economic, technological, and sociopolitical forces in Japanese society. Some theories explain it as the legacy of Japanese feudalism or as part of a system of employer "paternalism" (see above *Industrial and organizational relations*), but most important has been what can be called a labour-market "dualism." This evolved as Japan rapidly industrialized with sharply separated work forces for the relatively few large-scale, technologically advanced oligopolies on the one hand and for the millions of less secure small- and medium-size firms on the other hand. Considerable differentials in wages, benefits, working conditions, and employment security have long favoured the larger firms, so that a major reason to unionize within such enterprises lies in shared motivations among permanent workers to protect their advantages while simultaneously avoiding harm to their company's competitive strength.

In order to obtain and preserve gains and to avoid divisions, most unions seek coordination and guidance through industrywide federations and national centres. Upper-level organizations, although less well-financed, gradually have gained influence over enterprise unions despite decades of severe ideological rivalry, which began in the 1920s and revived with Japan's defeat in World War II. From the 1950s to the 1980s, Sōhyō, the Socialists' backbone, and Dōmei, the Democratic Socialist mainstay, fiercely competed, but, along with two lesser centres, they finally achieved unity in 1989 with the founding of Rengō (Japanese Trade Union Confederation), embracing almost eight million members. Rengō potentially offers a broadened role for organized labour. It aims to shift union power from the enterprise to upper levels by merging the numerous industrial federations, embracing millions of unaffiliated union members, and organizing the unorganized in cross-enterprise union structures.

In 1955 Sōhyō successfully coordinated union demands by launching the first *shuntō* ("spring offensive"); this has since been continued annually for the bargaining of

Enterprise unionism

Shuntō

general wage and benefit increases in April, when Japan's fiscal year begins. *Shuntō* counters the tendency toward disparate settlements at the enterprise level, where union-management negotiations formally occur, and also spills over into nonunion sectors, thus resembling an "incomes policy" mechanism. *Shuntō* subject matter has gradually broadened to include issues such as work hours, pensions, and housing, as well as large wage bonuses paid once or more each year.   (S.B.L.)

The developing world

Unionism in the developing regions, or Third World, has been largely shaped by the structure of their economies. From the turn of the 20th century, there was a gradual decline in the proportion of Third World workers engaged in agriculture, but even so, until World War II fully three-quarters of the active population was engaged in farming. The numbers engaged in manufacturing increased from 26 million to 46 million between 1900 and 1960, but as a proportion of the labour force they represented a mere 8 percent. During the same period, the number of workers engaged in extractive industries increased threefold, reflecting the importance of these activities during the colonial period, but as a proportion of the working population they represented a mere 1 percent. Service-sector employment also increased threefold between 1900 and 1960, but in this case it embraced a considerable 18 percent of the work force and a massive absolute number of 92 million workers. Across these sectors of employment, trade unionism developed unevenly, and in various phases of history one or the other was dominant. In all cases the objective economic determinants of trade unionism—*i.e.,* whether prevailing conditions were favourable or not to its development—would prove crucial, and they set the context in which labour organized.

Union growth among export industries

The first stable trade unions in many Third World countries were located within the export sector. By the beginning of the 20th century, railroad workers, dockers, and miners had formed strong labour organizations. These workers, who were integrated into the outward-oriented economies typical of the colonial division of labour, held considerable bargaining power through their ability to disrupt a major economic activity. For example, when in 1885 Hong Kong workers refused to unload a French warship, their action spread to coolies, boatmen, and rickshaw pullers. The strong group consciousness of dockworkers in African countries made them among the first to take collective class action. Railway workers, too, were as important in Ghana as they were in Argentina in organizing the early labour movement. And miners, for example in Chile and South Africa, have retained a considerable political influence through their strong and stable union organization in spite of their reduced numbers in relative terms. Once industrialization spread beyond these "enclaves" of the export sector, wider layers of workers, such as those engaged in textiles, began to organize.

A new international division of labour that emerged after World War II led to the consolidation of a significant manufacturing sector in a number of Third World countries. From the textile industry to automobile manufacturing and electronics, large factories and a transformed labour process created the conditions for a new wave of union organization. In Brazil during the 1970s, for example, organization within the workplace led to a powerful labour movement spearheaded by the metalworkers' union. In South Africa, likewise, the rise of new black trade unions in the 1970s was reflected in an increased level of organization at factory level. Similar processes could be discerned in South Korea and the Philippines. As opposed to the early government-controlled trade unions, this "new wave" of unionism had much deeper roots in the workplace. Nevertheless, the role of trade unions in the Third World has remained predominantly defensive, organizing work forces that have been created by the international division of labour and seeking through collective effort to defend living standards and improve working conditions. Their success in so doing is sporadic and very uneven across countries.

The public sector is relatively well organized in many Third World countries, either in spite of or because of government attitudes. Freedom of association for agricultural workers has also been achieved in most countries, although this is more readily achieved in big plantations with a stable labour force than in the traditional subsistence-farming sector. In the newly industrializing countries of East Asia, there are growing numbers of organizable workers owing to the economic modernization that has taken place there, although in general (with the exception of South Korea) labour organization has stagnated. In Africa, some countries such as Tanzania have promoted rural trade unions in particular, but in general the potentially organizable labour force in large enterprises is but a small minority of the working classes. In the huge "informal" sector, which is so prevalent in the Third World, unionization is even more difficult. In some countries, such as India, there have been some moves by industrial workers to extend their organization to cover unregistered casual and rural workers. The sheer size of this sector and its role in the economy mean that it has genuine bargaining power and can indeed force the pace for trade unions, which tend to neglect the smaller industrial units and the nonpermanent work force.

Organizing the "informal" sector

There is a close link between the level of socioeconomic development and the degree of labour organization in the Third World. Thus, Argentina has a degree of unionization approaching 40 percent, whereas the Dominican Republic has less than 10 percent trade-union membership. Likewise, Singapore has a far greater proportion of trade-union members than Papua New Guinea. Overall, there emerges a picture of incomplete unionization in the Third World, with only a handful approaching 40 percent, and most countries falling below 20 percent. Such quantitative analysis has its limits, however. It is equally important to assess the level of control that each trade-union movement has over the labour market. In addition, it is the distribution of the labour force across different occupational categories that sets the framework in which a trade-union movement develops. Exactly how it operates within these constraints depends on a range of political factors not considered here.   (R.Mu.)

Organization of work. ÉMILE DURKHEIM, *Émile Durkheim on the Division of Labor in Society,* trans. by W.D. HALLS (1984, which was originally published in French, 1893), started serious consideration of the organization of work in society. MELVIN KRANZBERG and JOSEPH GIES, *By the Sweat of Thy Brow: Work in the Western World* (1975, reprinted 1986), is a later popular survey.

For the organization of work from prehistoric to classical times, see ROBERT J. BRAIDWOOD, *Prehistoric Men,* 8th ed. (1975); AHMED FAKHRY, *The Pyramids,* 2nd ed. (1969, reprinted 1974); CARL ROEBUCK (ed.), *The Muses at Work: Arts, Crafts, and Professions in Ancient Greece and Rome* (1969); and J.G. LANDELS, *Engineering in the Ancient World* (1978, reprinted 1981).

Medieval and early modern developments in the Western world are treated in JEAN GIMPEL, *The Medieval Machine: The Industrial Revolution of the Middle Ages,* 2nd ed. (1988; originally published in French, 1975); and, most fully, in FERNAND BRAUDEL, *Civilization and Capitalism, 15th–18th Century,* 3 vol. (1981–84; originally published in French, 1979). Changes in the organization of work with the development of the factory system in the early Industrial Revolution are covered in PAUL MANTOUX, *The Industrial Revolution in the Eighteenth Century: An Outline of the Beginnings of the Modern Factory System in England,* rev. ed. (1961, reissued with a new foreword, 1983; originally published in French, 1905). The Industrial Revolution itself is the subject of many studies, the most notable in relation to the organization of work being E.P. THOMPSON, *The Making of the English Working Class,* new ed. (1968, reprinted 1980); WILLIAM H. SEWELL, JR., *Work and Revolution in France: The Language of Labor from the Old Regime to 1848* (1980); DAVID A. HOUNSHELL, *From the American System to Mass Production, 1800–1932: The Development of Manufacturing Technology in the United States* (1984); and GEORGES FRIEDMANN, *The Anatomy of Work: Labor, Leisure, and the Implications of Automation* (1962, reprinted 1978; originally published in French, 1956).

For scientific management see FREDERICK WINSLOW TAYLOR, *The Principles of Scientific Management* (1911, reprinted 1985);

and DANIEL NELSON, *Frederick W. Taylor and the Rise of Scientific Management* (1980). ELTON MAYO, *The Human Problems of an Industrial Civilization*, 2nd ed. (1946), and *The Social Problems of an Industrial Civilization* (1945, reprinted 1977), are two major summations by a pioneer industrial sociologist. Other major accounts of the modern factory system before the advent of automation are W. LLOYD WARNER and J.O. LOW, *The Social System of the Modern Factory: The Strike: A Social Analysis* (1947, reprinted 1976); and CHARLES R. WALKER and ROBERT H. GUEST, *The Man on the Assembly Line* (1952, reprinted 1979).

The development of automation and its effect on the organization of work are treated in DAVID F. NOBLE, *Forces of Production: A Social History of Industrial Automation* (1984); MARVIN MINSKY (ed.), *Robotics* (1985); HARLEY SHAIKEN, *Work Transformed: Automation and Labor in the Computer Age* (1985); DANIEL B. CORNFIELD (ed.), *Workers, Managers, and Technological Change: Emerging Patterns of Labor Relations* (1987); ELI GINZBERG, THIERRY J. NOYELLE, and THOMAS M. STANBACK, JR., *Technology and Employment: Concepts and Clarifications* (1986); TOM FORESTER (ed.), *The Microelectronics Revolution: The Complete Guide to the New Technology and Its Impact on Society* (1980); E. FOSSUM (ed.), *Computerization of Working Life*, trans. from Norwegian (1983); and SHOSHANA ZUBOFF, *In the Age of the Smart Machine: The Future of Work and Power* (1988).

Most notable among the growing number of studies of the working role of women are BARBARA A. HANAWALT (ed.), *Women and Work in Preindustrial Europe* (1986); LINDSEY CHARLES and LORNA DUFFIN, *Women and Work in Pre-industrial England* (1985); ALICE KESSLER-HARRIS, *Out to Work: A History of Wage-Earning Women in the United States* (1982); and RUTH SCHWARTZ COWAN, *More Work for Mother: The Ironies of Household Technology from the Open Hearth to the Microwave* (1983).

Migrant workers are treated in JAN LUCASSEN, *Migrant Labour in Europe, 1600–1900: The Drift to the North Sea* (1987; originally published in Dutch, 1984); ROBIN COHEN, *The New Helots: Migrants in the International Division of Labour* (1987); and PHILIP L. MARTIN, *Harvest of Confusion: Migrant Workers in U.S. Agriculture* (1988). (M.Kr.)

Industrial and organizational relations. Important works in the field of industrial relations include SIDNEY WEBB and BEATRICE WEBB, *Industrial Democracy*, 2 vol. (1897, reissued in 1 vol., 1965), a classic theory in the British socialist tradition; JOHN R. COMMONS, *Institutional Economics: Its Place in Political Economy* (1934, reissued 1961), a summary of the theoretical ideas of the father of American industrial relations research; JOHN T. DUNLOP, *Industrial Relations Systems* (1958, reprinted 1977), a theoretical model that shaped the study of industrial relations between 1960 and 1980; JACK BARBASH, *The Elements of Industrial Relations* (1984), a modern statement on the nature of the employment relationship; RICHARD HYMAN, *Industrial Relations: A Marxist Introduction* (1975), an interpretation by a leading contemporary Marxist; THOMAS A. KOCHAN, HARRY C. KATZ, and ROBERT B. MCKERSIE, *The Transformation of American Industrial Relations* (1986), a study offering a strategic-choice model for interpretation of industrial relations; and RICHARD E. WALTON and ROBERT B. MCKERSIE, *A Behavioral Theory of Labor Negotiations: An Analysis of a Social Interaction System* (1965), a classic theory of the dynamics of negotiations. TAISHIRO SHIRAI (ed.), *Contemporary Industrial Relations in Japan* (1983), is a survey of the evolution of industrial relations in the country from World War ll to the end of the 1970s; and WOLFGANG STREEK, *Industrial Relations in West Germany: A Case Study of the Car Industry* (1984), is an in-depth look at the German industrial system.

Leading works in the area of organizational behaviour include CHESTER I. BARNARD, *The Functions of the Executive* (1938, reissued 1979), a classic statement on the nature of organizational relations by a prominent executive of his time; MICHEL CROZIER, *The Bureaucratic Phenomenon* (1964; originally published in French, 1964), an insightful study of the organizational behaviour in France; JAMES G. MARCH and HERBERT A. SIMON, *Organizations* (1958), a theoretical analysis based on a decision-making approach; DOUGLAS MCGREGOR, *The Human Side of Enterprise* (1960, reprinted 1985), a study of two contrasting sets of assumptions managers make toward employees' motivations and of the effects of these assumptions on managerial behaviour; *Industrial Democracy in Europe* (1981), a comparative empirical study of worker participation conducted by an interdisciplinary team of researchers from 12 European countries; MICHAEL J. PIORE and CHARLES F. SABEL, *The Second Industrial Divide: Possibilities for Prosperity* (1984), a discussion of the changes in work organization and relations in response to changing technologies and market conditions; EDWARD B. ROBERTS (ed.), *Generating Technological Innovation* (1987), a collection of articles on the movement of new products and

technologies from the laboratory to the market; and ANDREW M. PETTIGREW, *The Awakening Giant: Continuity and Change in Imperial Chemical Industries* (1985), a detailed study of the process of organizational change based on an example of a large British firm.

For studies of the changing work force, see JEYLAN T. MORTIMER and KATHRYN M. BORMAN (eds.), *Work Experience and Psychological Development Through the Life Span* (1988); GORDON E. O'BRIEN, *Psychology of Work and Unemployment* (1986); CHARLES H. SAVAGE and GEORGE F.F. LOMBARD, *Sons of the Machine: Case Studies of Social Change in the Workplace* (1986); MARC L. SILVER, *Under Construction: Work and Alienation in the Building Trades* (1986); SYLVIA ANN HEWLETT, ALICE S. ILCHMAN, and JOHN J. SWEENEY (eds.), *Family and Work: Bridging the Gap* (1986); JON MILLER, *Pathways in the Workplace: The Effects of Gender and Race on Access to Organizational Resources* (1986); CLARK KERR and PAUL D. STAUDOHAR (eds.), *Industrial Relations in a New Age* (1986); SHEILA B. KAMERMAN and ALFRED J. KAHN, *The Responsive Workplace: Employers and a Changing Labor Force* (1987); MARY ANN VON GLINOW, *The New Professionals: Managing Today's High-Tech Employees* (1988); LOIS FARRER COPPERMAN and FREDERICK D. KEAST, *Adjusting to an Older Work Force* (1983); STEVEN H. SANDELL (ed.), *The Problem Isn't Age: Work and Older Americans* (1987); and HELEN DENNIS (ed.), *Fourteen Steps in Managing an Aging Work Force* (1988). (T.A.K.)

Labour economics. Surveys of the field of labour economics include HENRY PHELPS BROWN, *The Economics of Labor* (1962); MALCOLM R. FISHER, *The Economic Analysis of Labour* (1971); JOHN T. ADDISON and W. STANLEY SIEBERT, *The Market for Labor: An Analytical Treatment* (1979); INGRID H. RIMA, *Labor Markets, Wages, and Employment* (1981); LLOYD G. REYNOLDS, STANLEY H. MASTERS, and COLLETTA H. MOSER, *Labor Economics and Labor Relations*, 9th ed. (1986); DANIEL S. HAMERMESH and ALBERT REES, *The Economics of Work and Pay*, 4th ed. (1988); HOWARD M. WACHTEL, *Labor and the Economy*, 2nd ed. (1988); and CAMPBELL R. MCCONNELL and STANLEY L. BRUE, *Contemporary Labor Economics*, 2nd ed. (1989).

CLARENCE D. LONG, *The Labor Force Under Changing Income and Employment* (1958), outlines the relation of the labour force to the population of a number of countries. Education is treated as a form of investment in GARY S. BECKER, *Human Capital: A Theoretical and Empirical Analysis, with Special Reference to Education*, 2nd ed. (1975, reprinted 1983). Racial, sexual, and age discrimination in employment is explored in ROBERT C. SMITH, *Equal Employment Opportunity* (1982); E. ROBERT LIVERNASH (ed.), *Comparable Worth: Issues and Alternatives*, 2nd ed. (1984); and HARISH C. JAIN and PETER J. SLOANE, *Equal Employment Issues: Race and Sex Discrimination in the United States, Canada, and Britain* (1981).

For studies of the impact of collective bargaining, see LLOYD G. REYNOLDS and CYNTHIA H. TAFT, *The Evolution of Wage Structure* (1956, reprinted 1970); and JOHN T. DUNLOP (ed.), *The Theory of Wage Determination* (1957, reprinted 1986). Theories of collective bargaining are surveyed in ALAN CODDINGTON, *Theories of the Bargaining Process* (1968); see also RICHARD E. WALTON and ROBERT B. MCKERSIE, *A Behavioral Theory of Labor Negotiations: An Analysis of a Social Interaction System* (1965); HAROLD M. LEVINSON, *Determining Forces in Collective Wage Bargaining* (1966); JOHN G. KILGOUR, *Preventive Labor Relations* (1981); BARRY T. HIRSCH and JOHN T. ADDISON, *The Economic Analysis of Unions: New Approaches and Evidence* (1986); and RICHARD B. FREEMAN and JAMES L. MEDOFF, *What Do Unions Do?* (1984).

For studies of wage structures and their determinants, see E.M. HUGH-JONES (ed.), *Wage-Structure in Theory and Practice* (1966); CLARK KERR, *Labor Markets and Wage Determination* (1977); GUY ROUTH, *Occupation and Pay in Great Britain, 1906–79*, 2nd ed. (1980); HENRY PHELPS BROWN, *The Inequality of Pay* (1977), and *Egalitarianism and the Generation of Inequality* (1988). Theories of differences in the rates of pay for different jobs are developed in BARBARA WOOTTON, *The Social Foundations of Wage Policy: A Study of Contemporary British Wage and Salary Structure*, 2nd ed. (1962); and HAROLD LYDALL, *The Structure of Earnings* (1968). The movement of the general level of pay, in money and real terms, is recorded and analyzed in HENRY PHELPS BROWN and MARGARET H. BROWNE, *A Century of Pay: The Course of Pay and Production in France, Germany, Sweden, the United Kingdom, and the United States of America, 1860–1960* (1968). Work and its compensation are discussed also in ELLIOTT JAQUES, *Free Enterprise, Fair Employment* (1982); JOHN W. WRIGHT, *The American Almanac of Jobs and Salaries*, 3rd ed. (1987); FELICITY SKIDMORE (ed.), *Social Security Financing* (1981); SIMON ROTTENBERG (ed.), *The Economics of Legal Minimum Wages* (1981); and JAMES E. MEADE, *Wage-Fixing* (1982). (E.H.P.B./W.A.Br.)

Trade unionism. *Great Britain, Australia, and New Zealand:* SIDNEY WEBB and BEATRICE WEBB, *The History of Trade Union-*

ism, rev. ed. (1920, reprinted 1975), is the pioneer work in British trade union history. This classic study has been revised and carried forward to the 1930s in a standard work, H.A. CLEGG, ALAN FOX, and A.F. THOMPSON, *A History of British Trade Unions Since 1889,* 2 vol. (1964–1985). A more popular, though also comprehensive, account is provided in HENRY PELLING, *A History of British Trade Unionism,* 4th ed. (1987). For the earlier phases of union history, see JOHN RULE (ed.), *British Trade Unionism, 1750–1850: The Formative Years* (1988); and E.H. HUNT, *British Labour History, 1815–1914* (1981). There is a valuable discussion of the relationship between British trade unions and the law, including the compulsory arbitration issue, in HENRY PELLING, *Popular Politics and Society in Late Victorian Britain,* 2nd ed. (1979).

British and Australian union developments are compared in the valuable HENRY PHELPS BROWN, *The Origins of Trade Union Power* (1983). Studies of the modern period of Australian union developments are offered in ROSS M. MARTIN, *Trade Unions in Australia: Who Runs Them, Who Belongs, Their Politics, Their Power,* 2nd ed. (1980); and D.W. RAWSON, *Unions and Unionists in Australia,* rev. ed. (1986). A detailed account of early Australian unions is J.T. SUTCLIFFE, *A History of Trade Unionism in Australia* (1921, reprinted 1967). KEITH SINCLAIR, *William Pember Reeves, New Zealand Fabian* (1965), provides a biography of the architect of compulsory arbitration in New Zealand, and the same author's *A History of New Zealand,* rev. ed. (1980), is valuable in setting union development in a broad historical context. See also H. ROTH, *Trade Unions in New Zealand Past and Present* (1973).   (J.C.Lo.)

United States and Canada: The best historical survey of the American movement is FOSTER RHEA DULLES and MELVYN DUBOFSKY, *Labor in America,* 4th ed. (1984). The findings of much recent scholarship on the 19th century are presented in BRUCE LAURIE, *Artisans into Workers: Labor in Nineteenth-Century America* (1989). The 20th century is summarily covered in JAMES R. GREEN, *The World of the Worker: Labor in Twentieth-Century America* (1980); ROBERT H. ZIEGER, *American Workers, American Unions, 1920–1985* (1986); and DAVID BRODY, *Workers in Industrial America: Essays on the Twentieth Century Struggle* (1980). MELVYN DUBOFSKY, *We Shall Be All: A History of the Industrial Workers of the World,* 2nd ed. (1988), is a standard work on the organization. DAVID MONTGOMERY, *The Fall of the House of Labor: The Workplace, the State, and American Labor Activism, 1865–1925* (1987), is fundamental on the period it covers. On the role of American labour law, the leading modern interpretation is CHRISTOPHER L. TOMLINS, *The State and the Unions: Labor Relations, Law, and the Organized Labor Movement in America, 1880–1960* (1985). HAROLD A. LOGAN, *Trade Unions in Canada: Their Development and Functioning* (1948), is a standard work; it can be supplemented for the modern period by STUART JAMIESON, *Industrial Relations in Canada,* 2nd ed. (1973); and ALTON W.J. CRAIG, *The System of Industrial Relations in Canada,* 3rd ed. (1990). JOHN CRISPO, *International Unionism: A Study in Canadian-American Relations* (1967); and GAD HOROWITZ, *Canadian Labour in Politics* (1968, reprinted 1977), explore two of the main themes of Canadian labour history. SEYMOUR MARTIN LIPSET (ed.), *Unions in Transition: Entering the Second Century* (1986), contains important comparative essays and also surveys later developments.   (Da.B.)

Western Europe: WALTER KENDALL, *The Labour Movement in Europe* (1975); and HANS SLOMP, *Labor Relations in Europe: A History of Issues and Developments* (1990), are introductory surveys. GARY MARKS, *Unions in Politics: Britain, Germany, and the United States in the Nineteenth and Early Twentieth Centuries* (1989), explores the logic of political unionism. National differences in industrial work organization and their relations with unionism are discussed in MARC MAURICE, FRANÇOIS SELLIER, and JEAN-JACQUES SILVESTRE, *The Social Foundations of Industrial Power: A Comparison of France and Germany* (1986; originally published in French, 1982). The emergence of the "postwar settlement" is analyzed in PETER GOUREVITCH, *Politics in Hard Times: Comparative Responses to International Economic Crises* (1986). The events of 1968 are documented and placed in perspective in COLIN CROUCH and ALESSANDRO PIZZORNO (eds.), *The Resurgence of Class Conflict in Western*

Europe Since 1968, 2 vol. (1978). Country studies of postwar unionism from the perspective of post-1968 developments are collected in PETER GOUREVITCH *et al., Unions and Economic Crisis: Britain, West Germany, and Sweden* (1984); and PETER LANGE, GEORGE ROSS, and MAURIZIO VANNICELLI, *Unions, Change, and Crisis: French and Italian Union Strategy and the Political Economy, 1945–1980* (1982). The two main works on neocorporatism are GERHARD LEHMBRUCH and PHILIPPE C. SCHMITTER (eds.), *Patterns of Corporatist Policy-Making* (1982); and PHILIPPE C. SCHMITTER and GERHARD LEHMBRUCH (eds.), *Trends Toward Corporatist Intermediation* (1979). JOHN H. GOLDTHORPE (ed.), *Order and Conflict in Contemporary Capitalism* (1984), analyzes the role of unions in the European political economies of the 1970s. For a comprehensive descriptive study of modern West European unions, see JELLE VISSER, *In Search of Inclusive Unionism* (1990).   (W.St.)

Eastern Europe: JAN F. TRISKA and CHARLES GATI (eds.), *Blue-Collar Workers in Eastern Europe* (1981), presents essays—some thematic, some by individual country—by leading experts on the topics of politics and economics of workers and unions in communist states. Union developments from the 1917 revolution to the post-1945 period are analyzed by an expert on Soviet political and economic affairs in ISAAC DEUTSCHER, *Soviet Trade Unions: Their Place in Soviet Labour Policy* (1950, reprinted 1973). VICTORIA E. BONNELL, *Roots of Rebellion: Workers' Politics and Organizations in St. Petersburg and Moscow, 1900–1914* (1983), places union development in a comparative European framework. Analysis of the role of unions in the later Soviet political structure is offered in BLAIR A. RUBLE, *Soviet Trade Unions: Their Development in the 1970s* (1981). FELIKS GROSS, *The Polish Worker: A Study of a Social Stratum* (1945), is a sociological and historical study embracing the whole of the 19th century and the pre-World War II period of the 20th; ROMAN LABA, *The Roots of Solidarity* (1991), analyzes more recent developments.   (D.P.K.)

Japan: TAISHIRO SHIRAI (ed.), *Contemporary Industrial Relations in Japan* (1983), is a collection of authoritative analyses by leading Japanese scholars, including the editor's insightful study of enterprise unionism. KAZUO KOIKE, *Understanding Industrial Relations in Modern Japan,* trans. from Japanese (1988), portrays internal labour markets and their effect on unions and other labour institutions. TAISHIRO SHIRAI and HARUO SHIMADA, "Japan," pp. 241–322 in JOHN T. DUNLOP and WALTER GALENSON (eds.), *Labor in the Twentieth Century* (1978), offers a highly useful summary of historical and statistical materials up to the 1970s. KAZUO OKOCHI, BERNARD KARSH, and SOLOMON B. LEVINE (eds.), *Workers and Employers in Japan: The Japanese Employment Relations System* (1973), covers all major aspects of the postwar system, including unions, prior to the 1973–74 oil crisis. Analysis of union, employer, and government relations in the decade following the oil crisis is found in KOJI TAIRA and SOLOMON B. LEVINE, "Japan's Industrial Relations: A Social Compact Emerges," pp. 247–300 in HERVEY JURIS, MARK THOMPSON, and WILBUR DANIELS (eds.), *Industrial Relations in a Decade of Economic Change* (1985). The English-language publications of the Japan Institute of Labour are an important source of information.   (S.B.L.)

The developing world: ROSALIND E. BOYD, ROBIN COHEN, and PETER C.W. GUTKIND (eds.), *International Labour and the Third World: The Making of a New Working Class* (1987), examines class formation and the labour movement in various areas. ROBIN COHEN, PETER C.W. GUTKIND, and PHYLLIS BRAZIER (eds.), *Peasants and Proletarians: The Struggles of Third World Workers* (1979), focuses on forms of labour organization and strategies of working class action. *World Labour Report* (irregular), issued by the International Labour Office, provides systematic coverage of key issues of organized labour. RONALDO MUNCK, *The New International Labour Studies* (1988), offers an overview of the field as applied to the Third World. ROGER SOUTHALL (ed.), *Trade Unions and the New Industrialization of the Third World* (1988), examines the relationship between the "new international division of labour" and labour organization. IMMANUEL WALLERSTEIN (ed.), *Labor in the World Social Structure* (1983), presents a collection of papers from a Soviet-American symposium, covering various aspects of labour's role in the Third World.   (R.Mu.)

The World Wars

W orld War I (1914–18) and World War II (1939–45) are so called because they were wars in which virtually all of the most powerful nations of the world were involved, either on one side or the other, and because they were fought over large areas of the globe, on both land and sea. World War I pitted Germany, Austria-Hungary, and Turkey against France, Great Britain, Russia, the United States, China, and a host of smaller nations. In World War II, Japan and the Fascist nations of Germany and Italy confronted the Soviet Union, the United States, Great Britain, France, China, and many smaller nations. World War II was a truly global conflict that was fought not only throughout the European continent but also in the islands of the Pacific Ocean, in China and Southeast Asia, in North Africa, and throughout the world's oceans.

The world wars are the great watersheds of 20th-century geopolitical history. World War I led to the fall of four great imperial dynasties (in Germany, Russia, Austria-Hungary, and Turkey), resulted in the Bolshevik Revolution in Russia, and, in its destabilization of European society, laid the groundwork for World War II. World War II resulted

in the extension of the Soviet Union's power to the nations of eastern Europe, enabled a Communist movement to eventually achieve power in China, and marked the decisive shift of power in the world away from the states of western Europe and toward the United States and the Soviet Union. The world wars were almost unprecedented in their slaughter, carnage, and destruction, as mechanized armies of millions of soldiers destroyed both each other and the territories they were fighting over. The 40,000,-000–50,000,000 deaths incurred in World War II make it the bloodiest conflict as well as the largest war in history.

This article treats the military course and the diplomatic history of World Wars I and II. Other aspects of the world wars are treated in several articles in the *Macropædia*. The wars' causes and consequences, as well as the political and other events leading up to them and resulting from them, are treated in INTERNATIONAL RELATIONS, 20TH-CENTURY. The strategic and tactical considerations of the wars' participants are treated in WAR, THE THEORY AND CONDUCT OF, while the weapons and weapons systems used in the wars are treated in WAR, THE TECHNOLOGY OF.

The article is divided into the following sections:

WORLD WAR I

THE OUTBREAK OF WAR

With Serbia already much aggrandized by the two Balkan Wars (1912–13, 1913), Serbian nationalists turned their attention back to the idea of "liberating" the South Slavs of Austria-Hungary. Colonel Dragutin Dimitrijević, head of Serbia's military intelligence, was also, under the alias "Apis," head of the secret society Union or Death, pledged to the pursuit of this pan-Serbian ambition. Believing that the Serbs' cause would be served by the death of the Austrian archduke Francis Ferdinand, heir presumptive to the Austrian emperor Francis Joseph, and learning that the Archduke was about to visit Bosnia on a tour of military inspection, Apis plotted his assassination. Nikola Pašić, the Serbian prime minister and an enemy of Apis, heard of the plot and warned the Austrian government of it, but his message was too cautiously worded to be understood.

At 11:15 AM, on June 28, 1914, in the Bosnian capital, Sarajevo, Francis Ferdinand and his morganatic wife, Sophie, duchess of Hohenberg, were shot dead by a Bosnian Serb, Gavrilo Princip.

The chief of the Austro-Hungarian general staff, Franz, Graf Conrad von Hötzendorf, and the foreign minister, Leopold, Graf von Berchtold, saw the crime as the occasion for measures to humiliate Serbia and so to enhance Austria-Hungary's prestige in the Balkans; and Conrad had already (October 1913) been assured by William II of

Germany's support if Austria-Hungary should start a preventive war against Serbia. This assurance was confirmed in the week following the assassination, before William, on July 6, set off upon his annual cruise to the North Cape, off Norway.

The Austrians decided to present an unacceptable ultimatum to Serbia and then to declare war, relying on Germany to deter Russia from intervention. Though the terms of the ultimatum were finally approved on July 19, its delivery was postponed to the evening of July 23, since by that time the French president, Raymond Poincaré, and his premier, René Viviani, who had set off on a state visit to Russia on July 15, would be on their way home and therefore unable to concert an immediate reaction with their Russian allies. When the delivery was announced, on July 24, Russia declared that Austria-Hungary must not be allowed to crush Serbia.   The Austrian ultimatum

Serbia replied to the ultimatum on July 25, accepting most of its demands but protesting against two of them, namely, that Serbian officials (unnamed) should be dismissed at Austria-Hungary's behest and that Austro-Hungarian officials should take part, on Serbian soil, in proceedings against organizations hostile to Austria-Hungary. Though Serbia offered to submit the issue to international arbitration, Austria-Hungary promptly severed diplomatic relations and ordered partial mobilization.

Home from his cruise on July 27, William learned on July 28 how Serbia had replied to the ultimatum. At once he instructed the German Foreign Office to tell Austria-Hungary that there was no longer any justification for war and that it should content itself with a temporary occupation of Belgrade. But, meanwhile, the German Foreign Office had been giving such encouragement to Berchtold that already on July 27 he had persuaded Francis Joseph to authorize war against Serbia. War was, in fact, declared on July 28, and Austro-Hungarian artillery began to bombard Belgrade the next day. Russia then ordered partial mobilization against Austria-Hungary; and on July 30, when Austria-Hungary was riposting conventionally with an order of mobilization on its Russian frontier, Russia ordered general mobilization. Germany, which since July 28 had still been hoping, in disregard of earlier warning hints from Great Britain, that Austria-Hungary's war against Serbia could be "localized" in the Balkans, was now disillusioned insofar as eastern Europe was concerned. On July 31 Germany sent a 24-hour ultimatum requiring Russia to halt its mobilization and an 18-hour ultimatum requiring France to promise neutrality in the event of war between Russia and Germany.

Both Russia and France predictably ignored these demands. On August 1, Germany ordered general mobilization and declared war against Russia, and France likewise ordered general mobilization. The next day, Germany sent troops into Luxembourg and demanded from Belgium free passage for German troops across its neutral territory. On August 3 Germany declared war against France.

In the night of August 3–4 German forces invaded Belgium. Thereupon, Great Britain, which had no concern with Serbia and no express obligation to fight either for Russia or for France but was expressly committed to defend Belgium, on August 4 declared war against Germany. **The German invasion of Belgium**

Austria-Hungary declared war against Russia on August 5; Serbia against Germany on August 6; Montenegro against Austria-Hungary on August 7 and against Germany on August 12; France and Great Britain against Austria-Hungary on August 10 and on August 12, respectively; Japan against Germany on August 23; Austria-Hungary against Japan on August 25 and against Belgium on August 28.

Romania had renewed its secret anti-Russian alliance of 1883 with the Central Powers on Feb. 26, 1914, but now chose to remain neutral. Italy had confirmed the Triple Alliance on Dec. 7, 1912, but could now propound formal arguments for disregarding it: first, Italy was not obliged to support its allies in a war of aggression; second, the original treaty of 1882 had stated expressly that the alliance was not against England.

On Sept. 5, 1914, Russia, France, and Great Britain concluded the Treaty of London, each promising not to make a separate peace with the Central Powers. Thenceforth, they could be called the Allied, or Entente, Powers, or simply the Allies.

German and Allied movements on the Western Front, August–September 1914.

The outbreak of war in August 1914 was generally greeted with confidence and jubilation by the peoples of Europe, among whom it inspired a wave of patriotic feeling and celebration. Few people imagined how long or how disastrous a war between the great nations of Europe could be, and most believed that their country's side would be victorious within a matter of months. The war was welcomed either patriotically, as a defensive one imposed by national necessity, or idealistically, as one for upholding right against might, the sanctity of treaties, and international morality.

Forces and resources of the combatant nations in 1914. When war broke out the Allied Powers possessed greater overall demographic, industrial, and military resources than the Central Powers and enjoyed easier access to the oceans for trade with neutral countries, particularly with the United States. Table 1 shows the population, steel production, and armed strengths of the two rival coalitions in 1914.

All the initial belligerents in World War 1 were self-sufficient in food except Great Britain and Germany. Great Britain's industrial establishment was slightly superior to Germany's (17 percent of world trade in 1913 as compared with 12 percent for Germany), but Germany's diversified chemical industry facilitated the production of ersatz, or substitute, materials, which compensated for the worst shortages ensuing from the British wartime blockade. The German chemist Fritz Haber was already developing a process for the fixation of nitrogen from air; this process made Germany self-sufficient in explosives and thus no longer dependent on imports of nitrates from Chile.

Table 1: Strength of the Belligerents, Aug. 4, 1914

resources	Central Powers	Allied Powers
Population (in millions)	115.2	265.5
Steel production (in millions of metric tons)	17.0	15.3
Army divisions available for mobilization in August 1914	146	212
Modern battleships	20	39

Of all the initial belligerent nations, only Great Britain had a volunteer army, and this was quite small at the start of the war. The other nations had much larger conscript armies that required three to four years of service from able-bodied males of military age, to be followed by several years in reserve formations. Military strength on land was counted in terms of divisions composed of 12,000–20,000 officers and men. Two or more divisions made up an army corps, and two or more corps made up an army. An army could thus comprise anywhere from 50,000 to 250,000 men.

The land forces of the belligerent nations at the outbreak of war in August 1914 are shown in Table 2.

Table 2: Land Forces of the Belligerents, Aug. 4, 1914

country	regular divisions (with number of field armies)	other land forces	total manpower
Central Powers			
Germany	98 (8)	27 *Landwehr* brigades	1,900,000
Austria-Hungary	48 (6)		450,000
Allied Powers			
Russia	102* (6)		1,400,000
France	72 (5)		1,290,000
Serbia	11 (3)		190,000
Belgium	7 (1)	69,000 fortress troops	186,000
Great Britain	6 (1)	14 territorial divisions†	120,000

*Russia planned to have 114 divisions in the field three months after mobilization.
†Restricted in 1914 to service at home.

The higher state of discipline, training, leadership, and armament of the German Army reduced the importance of the initial numerical inferiority of the armies of the Central Powers. Because of the comparative slowness of mobilization, poor higher leadership, and lower scale of armament of the Russian armies, there was an approxi-

mate balance of forces between the Central Powers and the Allies in August 1914 that prevented either side from gaining a quick victory.

Germany and Austria also enjoyed the advantage of "interior lines of communication," which enabled them to send their forces to critical points on the battlefronts by the shortest route. According to one estimate, Germany's railway network made it possible to move eight divisions simultaneously from the Western Front to the Eastern Front in four and a half days.

Even greater in importance was the advantage that Germany derived from its strong military traditions and its cadre of highly efficient and disciplined regular officers. Skilled in directing a war of movement and quick to exploit the advantages of flank attacks, German senior officers were to prove generally more capable than their Allied counterparts at directing the operations of large troop formations.

Table 3: British and German Naval Strength, August 1914

type	British	German
Dreadnought battleships	20	14
Battle cruisers	9	4
Pre-dreadnought battleships	39	22
Armoured cruisers	34	9
Cruisers	64	41
Destroyers	301*	144
Submarines	65	28

*Including Canadian, Australian, and New Zealand destroyers of all classes.

Sea power was largely reckoned in terms of capital ships, or dreadnought battleships and battle cruisers having extremely large guns. Despite intensive competition from the Germans, the British had maintained their superiority in numbers, with the result that, in capital ships, the Allies had an almost two-to-one advantage over the Central Powers. Table 3 compares the strength of the two principal rivals at sea, Great Britain and Germany.

The numerical superiority of the British Navy, however, was offset by the technological lead of the German Navy in many categories, such as range-finding equipment, magazine protection, searchlights, torpedoes, and mines. Great Britain relied on the Royal Navy not only to ensure necessary imports of food and other supplies in wartime but also to sever the Central Powers' access to the markets of the world. With superior numbers of warships, Great Britain could impose a blockade that gradually weakened Germany by preventing imports from overseas.

Technology of war in 1914. The planning and conduct of war in 1914 were crucially influenced by the invention of new weapons and the improvement of existing types since the Franco-German War of 1870–71. The chief developments of the intervening period had been the machine gun and the rapid-fire field artillery gun. The modern machine gun, which had been developed in the 1880s and '90s, was a reliable belt-fed gun capable of sustained rates of extremely rapid fire; it could fire 600 bullets per minute with a range of more than 1,000 yards (900 metres). In the realm of field artillery, the period leading up to the war saw the introduction of improved breech-loading mechanisms and brakes. Without a brake or recoil mechanism, a gun lurched out of position during firing and had to be re-aimed after each round. The new improvements were epitomized in the French 75-millimetre field gun; it remained motionless during firing, and it was not necessary to readjust the aim in order to bring sustained fire on a target. Machine guns and rapid-firing artillery, when used in combination with trenches and barbed-wire emplacements, gave a decided advantage to the defense, since these weapons' rapid and sustained firepower could decimate a frontal assault by either infantry or cavalry.

There was a considerable disparity in 1914 between the deadly effectiveness of modern armaments and the doctrinal teachings of some armies. The South African War and the Russo-Japanese War had revealed the futility of frontal infantry or cavalry attacks on prepared positions when unaccompanied by surprise, but few military leaders

foresaw that the machine gun and the rapid-firing field gun would force armies into trenches in order to survive. Instead, war was looked upon by many leaders in 1914 as a contest of national wills, spirit, and courage. A prime example of this attitude was the French Army, which was dominated by the doctrine of the offensive. French military doctrine called for headlong bayonet charges of French infantrymen against the German rifles, machine guns, and artillery. German military thinking, under the influence of Alfred, Graf von Schlieffen, sought, unlike the French, to avoid frontal assaults but rather to achieve an early decision by deep flanking attacks; and at the same time to make use of reserve divisions alongside regular formations from the outset of war. The Germans paid greater attention to training their officers in defensive tactics using machine guns, barbed wire, and fortifications.

The initial stages of the war

INITIAL STRATEGIES

The Schlieffen Plan. Years before 1914, successive chiefs of the German general staff had been foreseeing Germany's having to fight a war on two fronts at the same time, against Russia in the east and France in the west, whose combined strength was numerically superior to the Central Powers'. The elder Helmuth von Moltke, chief of the German general staff from 1858 to 1888, decided that Germany should stay at first on the defensive in the west and deal a crippling blow to Russia's advanced forces before turning to counterattack the French advance. His immediate successor, Alfred von Waldersee, also believed in staying on the defensive in the west. Alfred, Graf von Schlieffen, who served as chief of the German general staff from 1891 to 1905, took a contrary view, and it was the plan he developed that was to guide Germany's initial wartime strategy. Schlieffen realized that on the outbreak of war Russia would need six full weeks to mobilize and assemble its vast armies, given the immense Russian countryside and population, the sparsity of the rail network, and the inefficiency of the government bureaucracy. Taking advantage of this fact, Schlieffen planned to initially adopt a purely defensive posture on the Eastern Front with a minimal number of troops facing Russia's slowly gathering armies. Germany would instead concentrate almost all of its troops in the west against France and would seek to bypass France's frontier fortifications by an offensive through neutral Belgium to the north. This offensive would sweep westward and then southward through the heart of northern France, capturing the capital and knocking that country out of the war within a few weeks. Having gained security in the west, Germany would then shift its troops to the east and destroy the Russian menace with a similar concentration of forces.

By the time of his retirement in 1905, Schlieffen had elaborated a plan for a great wheeling movement of the right (northern) wing of the German armies not only through central Belgium but also, in order to bypass the Belgian fortresses of Liège and Namur in the Meuse Valley, through the southernmost part of The Netherlands. With their right wing entering France near Lille, the Germans would continue to wheel westward until they were near the English Channel; they would then turn southward so as to sever the French armies' line of retreat from France's eastern frontier to the south; and the outermost arc of the wheel would sweep southward west of Paris, in order to avoid exposing the German right flank to a counterstroke launched from the city's outskirts. If the Schlieffen Plan succeeded, Germany's armies would simultaneously encircle the French Army from the north, overrun all of northeastern France, and capture Paris, thus forcing France into a humiliating surrender. The large wheeling movement that the plan envisaged required correspondingly large forces for its execution, in view of the need to keep up the numerical strength of the long-stretched marching line and the need to leave adequate detachments on guard over the Belgian fortresses that had been bypassed. Accordingly, Schlieffen allocated nearly seven-eighths of Germany's available troop strength to the execution of the wheeling movement by the right and

centre wings, leaving only one-eighth to face a possible French offensive on Germany's western frontier. Thus, the maximum of strength was allocated to the wheel's edge—that is, to the right. Schlieffen's plan was observed by the younger Helmuth von Moltke, who became chief of the general staff in 1906. Moltke was still in office when war broke out in 1914.

Eastern Front strategy, 1914. Russian Poland, the westernmost part of the Russian Empire, was a thick tongue of land enclosed to the north by East Prussia, to the west by German Poland (Poznania) and by Silesia, and to the south by Austrian Poland (Galicia). It was thus obviously exposed to a two-pronged invasion by the Central Powers; but the Germans, apart from their grand strategy of crushing France before attempting anything against Russia, took note of the poverty of Russian Poland's transportation network and so were disinclined to overrun that vulnerable area prematurely. Austria-Hungary, however, whose frontier with Russia lay much farther east than Germany's and who was moreover afraid of disaffection among the Slav minorities, urged some immediate action to forestall a Russian offensive. Moltke therefore agreed to the Austrian general staff's suggestion for a northeastward thrust by the Austrian Army into Russian Poland—the more readily because it would occupy the Russians during the crisis in France.

The Russians, for their part, would have preferred to concentrate their immediately available forces against Austria and to leave Germany undisturbed until their mobilization should have been completed. The French were anxious to relieve the German pressure against themselves, however, and so they persuaded the Russians to undertake an offensive involving two armies against the Germans in East Prussia simultaneously with one involving four armies against the Austrians in Galicia. The Russian Army, whose proverbial slowness and unwieldy organization dictated a cautious strategy, thus undertook an extra offensive against East Prussia that only an army of high mobility and tight organization could have hoped to execute successfully.

The strategy of the Western Allies, 1914. For some 30 years after 1870, considering the likelihood of another German war, the French high command had subscribed to the strategy of an initial defensive to be followed by a counterstroke against the expected invasion: a great system of fortresses was created on the frontier, but gaps were left in order to "canalize" the German attack. France's alliance with Russia and its entente with Great Britain, however, encouraged a reversal of plan, and after the turn of the century a new school of military thinkers began to argue for an offensive strategy. The advocates of the offensive *à l'outrance* ("to the utmost") gained control of the French military machine, and in 1911 a spokesman of this school, General J.-J.-C. Joffre, was designated chief of the general staff. He sponsored the notorious Plan XVII, with which France went to war in 1914.

Plan XVII gravely underestimated the strength that the Germans would deploy against France. Accepting the possibility that the Germans might employ their reserve troops along with regular troops at the outset, Plan XVII estimated the strength of the German Army in the west at a possible maximum of 68 infantry divisions. The Germans actually deployed the equivalent of 83½ divisions, counting *Landwehr* (reserve troops) and *Ersatz* (low-grade substitute troops) divisions. But French military opinion ignored or doubted this possibility; and during the war's crucial opening days, when the rival armies were concentrating and moving forward, the French Intelligence counted only Germany's regular divisions in its estimates of the enemy strength. This was a serious miscalculation. Plan XVII also miscalculated the direction and scope of the coming onslaught: though it foresaw an invasion through Belgium, it assumed that the Germans would take the route through the Ardennes, thereby exposing their communications to attack. Basing itself on the idea of an immediate and general offensive, Plan XVII called for a French thrust toward the Saar into Lorraine by the 1st and 2nd armies, while on the French left (the north) the 3rd and 5th armies, facing Metz and the Ardennes, respectively, stood ready either to launch an offensive between

Metz and Thionville or to strike from the north at the flank of any German drive through the Ardennes. When war broke out, it was taken for granted that the small British Expeditionary Force (BEF) under Sir John French should be used as an adjunct to France's forces, more or less as the French might see fit. It is clearly evident that the French were oblivious to the gigantic German offensive that was being aimed at their left (northern) wing.

THE WAR IN THE WEST, 1914

For the smooth working of their plan for the invasion of France, the Germans had preliminarily to reduce the ring fortress of Liège, which commanded the route prescribed for their 1st and 2nd armies and which was the foremost stronghold of the Belgian defenses. German troops crossed the frontier into Belgium on the morning of August 4. Thanks to the resolution of a middle-aged staff officer, Erich Ludendorff, a German brigade occupied the town of Liège itself in the night of August 5–6 and the citadel on August 7; but the surrounding forts held out stubbornly until the Germans brought their heavy howitzers into action against them on August 12. These 420-millimetre siege guns proved too formidable for the forts, which one by one succumbed. The vanguard of the German invasion was already pressing the Belgian field army between the Gete River and Brussels, when the last of the Liège forts fell on August 16. The Belgians then withdrew northward to the entrenched camp of Antwerp. On August 20 the German 1st Army entered Brussels while the 2nd Army appeared before Namur, the one remaining fortress barring the Meuse route into France.

The initial clashes between the French and German armies along the Franco-German and Franco-Belgian frontiers are collectively known as the Battle of the Frontiers. This group of engagements, which lasted from August 14 until the beginning of the First Battle of the Marne on September 6, was to be the largest battle of the war and was perhaps the largest battle in human history up to that time, given the fact that a total of more than 2,000,000 troops were involved. (See map.)

The planned French thrust into Lorraine, totaling 19 divisions, started on August 14 but was shattered by the German 6th and 7th armies in the Battle of Morhange-Sarrebourg (August 20–22). Yet this abortive French offensive had an indirect effect on the German plan. For when the French attack in Lorraine developed, Moltke was tempted momentarily to postpone the right-wing sweep and instead to seek a victory in Lorraine. This fleeting impulse led him to divert to Lorraine the six newly formed *Ersatz* divisions that had been intended to increase the weight of his right wing. This was the first of several impromptu decisions by Moltke that were to fatally impair the execution of the Schlieffen Plan.

Meanwhile, the German imperial princes who commanded armies on the Germans' left (southern) wing in Lorraine were proving unwilling to forfeit their opportunity for personal glory. Crown Prince Rupert of Bavaria on August 20 ordered his 6th Army to counterattack instead of continuing to fall back before the French advance as planned, and Crown Prince William of Germany ordered his 5th Army to do the same. The strategic result of these unplanned German offensives was merely to throw the French back onto a fortified barrier that both restored and augmented their power of resistance. Thus, the French were soon afterward enabled to dispatch troops to reinforce their left flank—a redistribution of strength that was to have far-reaching results in the decisive Battle of the Marne.

While this seesaw campaign in Lorraine was taking place, more decisive events were occurring to the northwest. The German attack on Liège had awakened Joffre to the reality of a German advance through Belgium, but not to its strength or to the wideness of its sweep. In preparing a counterattack against the German advance through Belgium, Joffre envisaged a pincer movement, with the French 3rd and 4th armies on the right and the 5th, supported by the BEF, on the left, to trap the Germans in the Meuse–Ardennes area south of Liège. The fundamental flaw in this new French plan was that the Germans had

deployed about 50 percent more troops than the French had estimated, and for a vaster enveloping movement. Consequently, while the right-hand claw of the French pincer (23 divisions) collided with the German 5th and 4th armies (20 divisions) in the Ardennes and was thrown back, the left-hand claw (13 French and four British divisions) found itself nearly trapped between the German 1st and 2nd armies, with a total of 30 divisions, on the one hand, and the 3rd, on the other. As the French 5th Army, under General Charles Lanrezac, was checked in its offensive south of the Sambre River by a German attack on August 21, the British, who reached Mons on August 22, at first agreed to stand there to cover Lanrezac's left; but on August 23 news of the fall of Namur and of the German 3rd Army's presence near Dinant induced Lanrezac to wisely order a general retreat; and on August 24 the British began their retreat from Mons, just in time to escape envelopment by the German 1st Army's westward march around their unprotected left flank.

At last Joffre realized the truth and the utter collapse of Plan XVII. Resolution was his greatest asset, and with imperturbable coolness he formed a new plan out of the wreckage. Joffre decided to swing the Allied centre and left back southwestward from the Belgian frontier to a line pivoted on the French fortress of Verdun and at the same time to withdraw some strength from the right wing so as to be able to station a newly created 6th Army on the extreme left, north of Paris. This plan might, in turn, have collapsed if the Germans had not themselves departed from Schlieffen's original plan due to a combination of Moltke's indecisiveness, poor communications between his headquarters and the field army commanders of the German right wing, and Moltke's resulting confusion about the developing tactical situation. In the first place, the German right wing was weakened by the subtraction of 11 divisions; four were detached to watch Antwerp and to invest French fortresses near the Belgian frontier, instead of using reserve and *Ersatz* troops for this as earlier intended, and seven more regular divisions were transferred to check the Russian advance into East Prussia (see below). In the second place, Alexander von Kluck, in command of the 1st Army, did, in fact, wheel inward north of Paris rather than southwest of the city.

Kluck's change of direction meant the inevitable abandonment of the original wide sweep around the far (western) side of Paris. Now the flank of this wheeling German line would pass the near side of Paris and across the face of the Paris defenses into the valley of the Marne River. The premature inward wheel of Kluck's 1st Army before Paris had been reached thus exposed the German extreme right wing to a flank attack and a possible counter-envelopment. On September 4 Moltke decided to abandon the original Schlieffen Plan and substituted a new one: the German 4th and 5th armies should drive southeastward from the Ardennes into French Lorraine west of Verdun and then converge with the southwestward advance of the 6th and 7th armies from Alsace against the Toul–Épinal line of fortifications, so as to envelop the whole French right wing; the 1st and 2nd armies, in the Marne Valley, should stand guard, meanwhile, against any French countermove from the vicinity of Paris. But such an Allied countermove had already begun before the new German plan could be put into effect.

Already on September 3, General J.-S. Gallieni, the military governor of Paris, had guessed the significance of the German 1st Army's swing inward to the Marne east of Paris. On September 4 Joffre, convinced by Gallieni's arguments, decisively ordered his whole left wing to turn about from their retreat and to begin a general offensive against the Germans' exposed right flank on September 6. The French 6th Army, under M.-J. Maunoury, forewarned by Gallieni, had actually begun attacking on September 5; and its pressure caused Kluck finally to engage the whole 1st Army in support of his right flank when he was still no farther up the Marne Valley than Meaux, with nothing but a cavalry screen stretched across the 30 miles between him and Karl von Bülow's 2nd Army (at Montmirail). While the French 5th Army was turning to attack Bülow, the BEF (between the 5th and the 6th armies) was still

The First
Battle of
the Marne

continuing its retreat for another day; but on September 9 Bülow learned that the British too had turned and were advancing into the gap between him and Kluck. He therefore ordered the 2nd Army to retreat, thus obliging Kluck to do likewise with the 1st. The counterattack of the French 5th and 6th armies and the BEF developed into a general counterattack by the entire left and centre of the French Army. This counterattack is known as the First Battle of the Marne. By September 11 the German retreat extended to all the German armies.

There were several reasons for this extraordinary turn of events. Chief among them was the utter exhaustion of the German soldiery of the right wing, some of whom had marched more than 150 miles (240 kilometres) under conditions of frequent battle. Their fatigue was ultimately a by-product of the Schlieffen Plan itself, for while the retreating French had been able to move troops by rail to various points within the circle formed by the front, the German troops had found their advance hampered by demolished bridges and destroyed rail lines. Their food and ammunition supply was consequently restricted, and the troops also had to make their advance by foot. Moreover, the Germans had underestimated the resilient spirit of the French troops, who had maintained their courage and morale and their confidence in their commanders. This fact was strikingly evidenced by the comparatively small number of prisoners taken by the Germans in the course of what was undeniably a precipitous French retreat.

Meanwhile, the assault by the German 6th and 7th armies on the defenses of the French eastern frontier had already proved a predictably expensive failure, and the German attempt at a partial envelopment pivoted on Verdun was abandoned. The German right wing withdrew northward from the Marne and made a firm stand along the Lower Aisne River and the Chemin des Dames ridge. Along the Aisne the preponderant power of the defense over the offense was reemphasized as the Germans repelled successive Allied attacks from the shelter of trenches. The First Battle of the Aisne marked the real beginning of trench warfare on the Western Front. Both sides were in the process of discovering that, in lieu of frontal assaults for which neither had the manpower readily available, the only alternative was to try to overlap and envelop the other's flank, in this case the one on the side pointing toward the North Sea and the English Channel. Thus began the "Race to the Sea," in which the developing trench networks of both sides were quickly extended northwestward until they reached the Atlantic at a point just inside coastal Belgium, west of Ostend.

The First Battle of the Marne succeeded in pushing the Germans back for a distance of 40 to 50 miles and thus saved the capital city of Paris from capture. In this respect it was a great strategic victory, since it enabled the French to renew their confidence and to continue the war. But the great German offensive, though unsuccessful in its object of knocking France out of the war, had enabled the Germans to capture a large portion of northeastern France. The loss of this heavily industrialized region, which contained much of the country's coal, iron, and steel production, was a serious blow to the continuation of the French war effort.

The Belgian Army, meanwhile, had fallen back to the fortress city of Antwerp, which ended up behind the German lines. The Germans began a heavy bombardment of Antwerp on September 28, and Antwerp surrendered to the Germans on October 10.

After the failure of his first two attempts to turn the Germans' western flank (one on the Somme, the other near Arras), Joffre obstinately decided to try once again yet farther north with the BEF—which in any case was being moved northward from the Aisne. The BEF, accordingly, was deployed between La Bassée and Ypres, while on the left the Belgians—who had wisely declined to participate in the projected attack—continued the front along the Yser down to the Channel. Erich von Falkenhayn, however, who on September 14 had succeeded Moltke as chief of the German general staff, had foreseen what was coming and had prepared a counterplan: one of his armies, transferred from Lorraine, was to check the expected offensive,

while another was to sweep down the coast and crush the attackers' left flank. The British attack was launched from Ypres on October 19, the German thrust the next day. Though the Belgians of the Yser had been under increasing pressure for two days already, both Sir John French and Ferdinand Foch, Joffre's deputy in the north, were slow to appreciate what was happening to their "offensive"; but in the night of October 29–30 the Belgians had to open the sluices on the Yser River to save themselves by flooding the Germans' path down the coast. The Battle of Ypres had its worst crises on October 31 and November 11 and did not die down into trench warfare until November 22.

By the end of 1914 the casualties the French had so far sustained in the war totaled about 380,000 killed and 600,000 wounded; the Germans had lost a slightly smaller number. With the repulse of the German attempt to break through at the Battle of Ypres, the strained and exhausted armies of both sides settled down into trench warfare. The trench barrier was consolidated from the Swiss frontier to the Atlantic; the power of modern defense had triumphed over the attack, and stalemate ensued. The military history of the Western Front during the next three years was to be a story of the Allies' attempts to break this deadlock.

THE EASTERN AND OTHER FRONTS, 1914

The war in the east, 1914. On the Eastern Front, greater distances and quite considerable differences between the equipment and quality of the opposing armies ensured a fluidity of the front that was lacking in the west. Trench lines might form, but to break them was not difficult, particularly for the German army, and then mobile operations of the old style could be undertaken.

Urged by the French to take offensive action against the Germans, the Russian commander in chief, Grand Duke Nicholas, took it loyally but prematurely, before the cumbrous Russian war machine was ready, by launching a pincer movement against East Prussia. Under the higher control of General Ya.G. Zhilinsky, two armies, the 1st, or Vilna, Army under P.K. Rennenkampf and the 2nd, or Warsaw, Army under A.V. Samsonov, were to converge, with a two-to-one superiority in numbers, on the German 8th Army in East Prussia from the east and the south, respectively. Rennenkampf's left flank would be separated by 50 miles from Samsonov's right flank.

Max von Prittwitz und Gaffron, commander of the 8th Army, with his headquarters at Neidenburg (Nidzica), had seven divisions and one cavalry division on his eastern front but only the three divisions of Friedrich von Scholtz's XX Corps on his southern. He was therefore dismayed to learn, on August 20, when the bulk of his forces had been repulsed at Gumbinnen (August 19–20) by Rennenkampf's attack from the east, that Samsonov's 13 divisions had crossed the southern frontier of East Prussia and were thus threatening his rear. He initially considered a general retreat, but when his staff objected to this, he approved their counterproposal of an attack on Samsonov's left flank, for which purpose three divisions were to be switched in haste by rail from the Gumbinnen front to reinforce Scholtz (the rest of the Gumbinnen troops could make their retreat by road). The principal exponent of this counterproposal was Lieutenant Colonel Max Hoffmann. Prittwitz, having moved his headquarters northward to Mühlhausen (Młynary), was surprised on August 22 by a telegram announcing that General Paul von Hindenburg, with Ludendorff as his chief of staff, was coming to supersede him in command. Arriving the next day, Ludendorff readily confirmed Hoffmann's dispositions for the blow at Samsonov's left.

Meanwhile, Zhilinsky was not only giving Rennenkampf time to reorganize after Gumbinnen but even instructing him to invest Königsberg instead of pressing on to the west. When the Germans on August 25 learned from an intercepted Russian wireless message (the Russians habitually transmitted combat directives "in clear," not in code) that Rennenkampf was in no hurry to advance, Ludendorff saw a new opportunity. Developing the plan put forward by Hoffmann, Ludendorff concentrated about six divisions against Samsonov's left wing. This force, inferior in strength, could not have been decisive, but

The Eastern Front, 1914–17.

terpiece, called the Battle of Tannenberg, was the destruction or capture of almost the whole of Samsonov's army. The history of imperial Russia's unfortunate participation in World War I is epitomized in the ignominious outcome of the Battle of Tannenberg.

The progress of the battle was as follows. Samsonov, his forces spread out along a front 60 miles long, was gradually pushing Scholtz back toward the Allenstein–Osterode (Olsztyn–Ostróda) line when, on August 26, Ludendorff ordered General Hermann von François, with the I Corps on Scholtz's right, to attack Samsonov's left wing near Usdau (Uzdowo). There, on August 27, German artillery bombardments threw the hungry and weary Russians into precipitate flight. François started to pursue them toward Neidenburg, in the rear of the Russian centre, and then made a momentary diversion southward, to check a Russian counterattack from Soldau (Działdowo). Two of the Russian 2nd Army's six army corps managed to escape southeastward at this point, and François then resumed his pursuit to the east. By nightfall on August 29 his troops were in control of the road leading from Neidenburg eastward to Willenberg (Wielbark). The Russian centre, amounting to three army corps, was now caught in the maze of forest between Allenstein and the frontier of Russian Poland. It had no line of retreat, was surrounded by the Germans, and soon dissolved into mobs of hungry and exhausted men who beat feebly against the encircling German ring and then allowed themselves to be taken prisoner by the thousands. Samsonov shot himself in despair on August 29. By the end of August the Germans had taken 92,000 prisoners and annihilated half of the Russian 2nd Army. Ludendorff's bold recall of the last German forces facing Rennenkampf's army was wholly justified in the event, since Rennenkampf remained utterly passive while Samsonov's army was surrounded.

Having received two fresh army corps (seven divisions) from the Western Front, the Germans now turned on the slowly advancing 1st Army under Rennenkampf. The latter was attacked on a line extending from east of Königsberg to the southern end of the chain of the Masurian Lakes during September 1–15 and was driven from East Prussia. As a result of these East Prussian battles Russia had lost about 250,000 men and, what could be afforded still less, much war matériel. But the invasion of East Prussia had at least helped to make possible the French comeback on the Marne by causing the dispatch of two German army corps from the Western Front.

Having ended the Russian threat to East Prussia, the Germans could afford to switch the bulk of their forces from that area to the Częstochowa–Kraków front in southwestern Poland, where the Austrian offensive, launched on August 20, had been rolled back by Russian counterattacks. A new plan for simultaneous thrusts by the Germans toward Warsaw and by the Austrians toward Przemyśl was brought to nothing by the end of October, as the Russians could now mount counterattacks in overwhelming strength, their mobilization being at last nearly completed. The Russians then mounted a powerful effort to invade Prussian Silesia with a huge phalanx of seven armies. Allied hopes rose high as the much-heralded "Russian steamroller" (as the huge Russian Army was called) began its ponderous advance. The Russian armies were advancing toward Silesia when Hindenburg and Ludendorff, in November, exploited the superiority of the German railway network: when the retreating German forces had crossed the frontier back into Prussian Silesia, they were promptly moved northward into Prussian Poland and thence sent southeastward to drive a wedge between the two armies of the Russian right flank. The massive Russian operation against Silesia was disorganized, and within a week four new German army corps had arrived from the Western Front. Ludendorff was able to use them to press the Russians back by mid-December to the Bzura–Rawka (rivers) line in front of Warsaw, and the depletion of their munition supplies compelled the Russians to also fall back in Galicia to trench lines along the Nida and Dunajec rivers.

The Serbian campaign, 1914. The first Austrian invasion of Serbia was launched with numerical inferiority

(margin note beside paragraph 2: The Battle of Tannenberg)

Ludendorff then took the calculated risk of withdrawing the rest of the German troops, except for a cavalry screen, from their confrontation with Rennenkampf and rushing them southwestward against Samsonov's right wing. Thus, August von Mackensen's XVII Corps was taken from near Gumbinnen and moved southward to duplicate the planned German attack on Samsonov's left with an attack on his right, thus completely enveloping the Russian 2nd Army. This daring move was made possible by the notable absence of communication between the two Russian field commanders, whom Hoffmann knew to personally dislike each other. Under the Germans' converging blows Samsonov's flanks were crushed and his centre surrounded during August 26–31. The outcome of this military mas-

Europe and the Mediterranean during World War I.

(part of one of the armies originally destined for the Balkan front having been diverted to the Eastern Front on August 18); and the able Serbian commander, Radomir Putnik, brought the invasion to an early end by his victories on the Cer Mountain (August 15–20) and at Šabac (August 21–24). In early September, however, Putnik's subsequent northward offensive on the Sava River, in the north, had to be broken off when the Austrians began a second offensive, against the Serbs' western front on the Drina River. After some weeks of deadlock, the Austrians began a third offensive, which had some success in the Battle of the Kolubara, and forced the Serbs to evacuate Belgrade on November 30; but by December 15 a Serbian counterattack had retaken Belgrade and forced the Austrians to retreat. Mud and exhaustion kept the Serbs from turning the Austrian retreat into a rout, but the victory sufficed to allow Serbia a long spell of freedom from further Austrian advances.

The Turkish entry. The entry of Turkey (or the Ottoman Empire, as it was then called) into the war as a German ally was the one great success of German wartime diplomacy. Since 1909 Turkey had been under the control of the Young Turks, over whom Germany had skillfully gained a dominating influence. German military instructors permeated the Turkish Army, and Enver Paşa, the leader of the Young Turks, saw alliance with Germany as the best way of serving Turkey's interests, in particular for protection against the Russian threat to the Straits. He therefore persuaded the grand vizier, Said Halim Paşa, to

make a secret treaty (negotiated late in July, signed on August 2) pledging Turkey to the German side if Germany should have to take Austria-Hungary's side against Russia. The unforeseen entry of Great Britain into the war against Germany alarmed the Turks, but the timely arrival of two German warships, the *Goeben* and the *Breslau*, in the Dardanelles on August 10 turned the scales in favour of Enver's policy. The ships were ostensibly sold to Turkey, but they retained their German crews. The Turks began detaining British ships, and more anti-British provocations followed, both in the Straits and on the Egyptian frontier. Finally the *Goeben* led the Turkish fleet across the Black Sea to bombard Odessa and other Russian ports (October 29–30). Russia declared war against Turkey on November 1; and the western Allies, after an ineffective bombardment of the outer forts of the Dardanelles on November 3, declared war likewise on November 5. A British force from India occupied Basra, on the Persian Gulf, on November 21. In the winter of 1914–15 Turkish offensives in the Caucasus and in the Sinai Desert, albeit abortive, served German strategy well by tying Russian and British forces down in those peripheral areas.

The *Goeben* and the *Breslau* in the Dardanelles

The war at sea, 1914–15. In August 1914 Great Britain, with 29 capital ships ready and 13 under construction, and Germany, with 18 and nine, were the two great rival sea powers. Neither of them at first wanted a direct confrontation: the British were chiefly concerned with the protection of their trade routes; the Germans hoped that mines and submarine attacks would gradually destroy Great Britain's

numerical superiority, so that confrontation could eventually take place on equal terms.

The first significant encounter between the two navies was that of the Helgoland Bight, on Aug. 28, 1914, when a British force under Admiral Sir David Beatty, having entered German home waters, sank or damaged several German light cruisers and killed or captured 1,000 men at a cost of one British ship damaged and 35 deaths. For the following months the Germans in European or British waters confined themselves to submarine warfare—not without some notable successes: on September 22 a single German submarine, or U-boat, sank three British cruisers within an hour; on October 7 a U-boat made its way into the anchorage of Loch Ewe, on the west coast of Scotland; on October 15 the British cruiser *Hawke* was torpedoed; and on October 27 the British battleship *Audacious* was sunk by a mine.

On December 15 battle cruisers of the German High Seas Fleet set off on a sortie across the North Sea, under the command of Admiral Franz von Hipper: they bombarded several British towns and then made their way home safely. Hipper's next sortie, however, was intercepted on its way out: on Jan. 24, 1915, in the Battle of the Dogger Bank, the German cruiser *Blücher* was sunk and two other cruisers damaged before the Germans could make their escape.

Abroad on the high seas, the Germans' most powerful surface force was the East Asiatic squadron of fast cruisers, including the *Scharnhorst,* the *Gneisenau,* and the *Nürnberg,* under Admiral Graf Maximilian von Spee. For four months this fleet ranged almost unhindered over the Pacific Ocean, while the *Emden,* having joined the squadron in August 1914, was detached for service in the Indian Ocean. The Germans could thus threaten not only merchant shipping on the British trade routes but also troopships on their way to Europe or the Middle East from India, New Zealand, or Australia. The *Emden* sank merchant ships in the Bay of Bengal, bombarded Madras (September 22), haunted the approaches to Ceylon, and had destroyed 15 Allied ships in all before it was caught and sunk off the Cocos Islands on November 9 by the Australian cruiser *Sydney.*

Meanwhile, Admiral von Spee's main squadron since August had been threading a devious course in the Pacific from the Caroline Islands toward the Chilean coast and had been joined by two more cruisers, the *Leipzig* and the *Dresden.* On November 1, in the Battle of Coronel, it inflicted a sensational defeat on a British force, under Sir Christopher Cradock, which had sailed from the Atlantic to hunt it down: without losing a single ship, it sank Cradock's two major cruisers, Cradock himself being killed. But the fortunes of the war on the high seas were reversed when, on December 8, the German squadron attacked the Falkland Islands (in the South Atlantic), probably unaware of the naval strength that the British, since Coronel, had been concentrating there under Admiral Sir Doveton Sturdee: two battle cruisers (the *Invincible* and *Inflexible,* each equipped with eight 12-inch guns) and six other cruisers. The German ships were suffering from wear and tear after their long cruise in the Pacific and were no match for the newer, faster British ships, which soon overtook them. The *Scharnhorst,* with Admiral von Spee aboard, was the first ship to be sunk, then the *Gneisenau,* followed by the *Nürnberg* and the *Leipzig.* The British ships, which had fought at long range so as to render useless the smaller guns of the Germans, sustained only 25 casualties in this engagement. When the German light cruiser *Dresden* was caught and sunk off the Juan Fernández Islands on March 14, 1915, commerce raiding by German surface ships on the high seas was at an end. It was just beginning by German submarines, however.

The belligerent navies were employed as much in interfering with commerce as in fighting each other. Immediately after the outbreak of war, the British had instituted an economic blockade of Germany, with the aim of preventing all supplies reaching that country from the outside world. The two routes by which supplies could reach German ports were: (1) through the English Channel and the Dover Straits, and (2) around the north of Scotland. A

The battles of Coronel and the Falkland Islands

minefield laid in the Dover Straits with a narrow free lane made it fairly easy to intercept and search ships using the Channel. To the north of Scotland, however, there was an area of more than 200,000 square miles (520,000 square kilometres) to be patrolled, and the task was assigned to a squadron of armed merchant cruisers. During the early months of the war, only absolute contraband such as guns and ammunition was restricted, but the list was gradually extended to include almost all material that might be of use to the enemy.

The prevention of the free passage of trading ships led to considerable difficulties among the neutral nations, particularly with the United States, whose trading interests were hampered by British policy. Nevertheless, the British blockade was extremely effective, and during 1915 the British patrols stopped and inspected more than 3,000 vessels, of which 743 were sent into port for examination. Outward-bound trade from Germany was brought to a complete standstill.

The Germans similarly sought to attack Great Britain's economy with a campaign against its supply lines of merchant shipping. In 1915, however, with their surface commerce raiders eliminated from the conflict, they were forced to rely entirely on the submarine.

The Germans began their submarine campaign against commerce by sinking a British merchant steamship (*Glitra*), after evacuating the crew, on Oct. 20, 1914. A number of other sinkings followed, and the Germans soon became convinced that the submarine would be able to bring the British to an early peace where the commerce raiders on the high seas had failed. On Jan. 30, 1915, Germany carried the campaign a stage further by torpedoing two Japanese liners (*Tokomaru* and *Ikaria*) without warning. They next announced, on February 4, that from February 18 they would treat the waters around the British Isles as a war zone in which all Allied merchant ships were to be destroyed, and in which no ship, whether enemy or not, would be immune.

Yet, whereas the Allied blockade was preventing almost all trade for Germany from reaching that nation's ports, the German submarine campaign yielded less satisfactory results. During the first week of the campaign seven Allied or Allied-bound ships were sunk out of 11 attacked, but 1,370 others sailed without being harassed by the German submarines. In the whole of March 1915, during which 6,000 sailings were recorded, only 21 ships were sunk, and in April only 23 ships from a similar number. Apart from its lack of positive success, the U-boat arm was continuously harried by Great Britain's extensive antisubmarine measures, which included nets, specially armed merchant ships, hydrophones for locating the noise of a submarine's engines, and depth bombs for destroying it underwater.

For the Germans, a worse result than any of the British countermeasures imposed on them was the long-term growth of hostility on the part of the neutral countries. Certainly the neutrals were far from happy with the British blockade, but the German declaration of the war zone and subsequent events turned them progressively away from their attitude of sympathy for Germany. The hardening of their outlook began in February 1915, when the Norwegian steamship *Belridge,* carrying oil from New Orleans to Amsterdam, was torpedoed and sunk in the English Channel. The Germans continued to sink neutral ships occasionally, and undecided countries soon began to adopt a hostile outlook toward this activity when the safety of their own shipping was threatened.

Much more serious was an action that confirmed the inability of the German command to perceive that a minor tactical success could constitute a strategic blunder of the most extreme magnitude. This was the sinking by a German submarine on May 7, 1915, of the British liner *Lusitania,* which was on its way from New York to Liverpool: though the ship was, in fact, carrying 173 tons of ammunition, it had nearly 2,000 civilian passengers, and the 1,198 people who were drowned included 128 U.S. citizens. The loss of the liner and so many of its passengers, including the Americans, aroused a wave of indignation in the United States, and it was fully expected that a declaration of war might follow. But the U.S. government

The Lusitania sunk

clung to its policy of neutrality and contented itself with sending several notes of protest to Germany. Despite this, the Germans persisted in their intention and, on August 17, sank the *Arabic,* which also had U.S. and other neutral passengers. Following a new U.S. protest, the Germans undertook to ensure the safety of passengers before sinking liners henceforth; but only after the torpedoing of yet another liner, the *Hesperia,* did Germany, on September 18, decide to suspend its submarine campaign in the English Channel and west of the British Isles, for fear of provoking the United States further. The German civilian statesmen had temporarily prevailed over the naval high command, which advocated "unrestricted" submarine warfare.

The loss of the German colonies. Germany's overseas colonies, virtually without hope of reinforcement from Europe, defended themselves with varying degrees of success against Allied attack.

Togoland was conquered by British forces from the Gold Coast (now Ghana) and by French forces from Dahomey (now Benin) in the first month of the war. In the Cameroons (German: Kamerun), invaded by Allied forces from the south, the east, and the northwest in August 1914 and attacked from the sea in the west, the Germans put up a more effective resistance, and the last German stronghold there, Mora, held out until Feb. 18, 1916.

Operations by South African forces in huge numerical superiority were launched against German South West Africa (Namibia) in September 1914 but were held up by the pro-German rebellion of certain South African officers who had fought against the British in the South African War of 1899–1902. The rebellion died out in February 1915, but the Germans in South West Africa nevertheless did not capitulate until July 9.

In Kiaochow, a small German enclave on the Chinese coast, the port of Tsingtao was the object of Japanese attack from September 1914. With some help from British troops and from Allied warships, the Japanese captured it on November 7. In October, meanwhile, the Japanese had occupied the Marianas, the Caroline Islands, and the Marshalls in the North Pacific, these islands being defenseless since the departure of Admiral von Spee's naval squadron.

In the South Pacific, Western Samoa fell without blood at the end of August 1914 to a New Zealand force supported by Australian, British, and French warships. In September an Australian invasion of Neu-Pommern (New Britain) won the surrender of the whole colony of German New Guinea within a few weeks.

Lettow-Vorbeck in East Africa

The story of German East Africa (comprising present-day Rwanda, Burundi, and continental Tanzania) was very different, thanks to the quality of the local askaris (European-trained African troops) and to the military genius of the German commander Paul von Lettow-Vorbeck. A landing of troops from India was repelled with ignominy by the Germans in November 1914. A massive invasion from the north, comprising British and colonial troops under the South African J.C. Smuts, was launched in February 1916, to be coordinated with a Belgian invasion from the west and with an independent British one from Nyasaland in the south; but though Dar es Salaam fell to Smuts and Tabora to the Belgians in September, Lettow-Vorbeck maintained his small force in being. In November 1917 he began to move southward across Portuguese East Africa (Germany had declared war on Portugal in March 1916); and, after crossing back into German East Africa in September 1918, he turned southwestward to invade Northern Rhodesia in October. Having taken Kasama on November 9 (two days before the German armistice in Europe), he finally surrendered on November 25. With some 12,000 men at the outset, he eventually tied down 130,000 or more Allied troops.

The years of stalemate

Rival strategies and the Dardanelles campaign, 1915–16. By late 1914 the state of deadlock on the Western Front had become clear to the governments of the warring countries and even to many members of their general staffs. Each side sought a solution to this deadlock, and the solutions varied in form and manner.

Erich von Falkenhayn had succeeded the dispirited Moltke as chief of the German general staff in September 1914. By the end of 1914 Falkenhayn seems to have concluded that although the final decision would be reached in the West, Germany had no immediate prospect of success there, and that the only practicable theatre of operations in the near future was the Eastern Front, however inconclusive those operations might be. Falkenhayn was convinced of the strength of the Allied trench barrier in France, so he took the momentous decision to stand on the defensive in the West.

Falkenhayn saw that a long war was now inevitable and set to work to develop Germany's resources for such a warfare of attrition. Thus, the technique of field entrenchment was carried to a higher pitch by the Germans than by any other country; Germany's military railways were expanded for the lateral movement of reserves; and the problem of the supply of munitions and of the raw materials for their manufacture was tackled so energetically and comprehensively that an ample flow was ensured from the spring of 1915 onward—a time when the British were only awakening to the problem. Here were laid the foundations of that economic organization and utilization of resources that was to be the secret of Germany's power to resist the pressure of the British blockade.

The western Allies were divided into two camps about strategy. Joffre and most of the French general staff, backed by the British field marshal Sir John French, argued for continuing assaults on the Germans' entrenched line in France, despite the continued attrition of French forces that this strategy entailed. Apart from this, the French high command was singularly lacking in ideas to break the deadlock of trench warfare. While desire to hold on to territorial gains governed the German strategy, the desire to recover lost territory dominated the French.

British-inspired solutions to the deadlock crystallized into two main groups, one tactical, the other strategical. The first was to unlock the trench barrier by inventing a machine that would be invulnerable to machine guns and capable of crossing trenches and would thus restore the tactical balance upset by the new preponderance of defensive over offensive power. The idea of such a machine was conceived by Colonel Ernest Swinton in October 1914, was nourished and tended in infancy by Winston Churchill, then first lord of the Admiralty, and ultimately, after months of experiment hampered by official opposition, came to maturity in 1916 in the weapon known as the tank. Some of the British strategists, on the other hand, argued that instead of seeking a breakthrough on the Germans' impregnable Western Front, the Allies should turn the whole position of the Central Powers either by an offensive through the Balkans or even by a landing on Germany's Baltic coast. Joffre and his supporters won the argument, and the Balkan projects were relinquished in favour of a concentration of effort on the Western Front. But misgivings were not silenced, and a situation arose that revived the Middle Eastern scheme in a new if attenuated form.

Early in January 1915 the Russians, threatened by the Turks in the Caucasus, appealed to the British for some relieving action against Turkey. The British, after acrimonious argument among themselves, decided in favour of "a naval expedition in February to bombard and take the Gallipoli Peninsula (the western shore of the Dardanelles), with Constantinople as its objective." Though subsequently it was agreed that army troops might be provided to hold the shores if the fleet forced the Straits, the naval attack began on February 19 without army support. When at last Sir Ian Hamilton's troops from Egypt began to land on the Turkish shores, on April 25, the Turks and their German commander, Otto Liman von Sanders, had had ample time to prepare adequate fortifications, and the defending armies were now six times as large as when the campaign opened.

Against resolute opposition from the local Turkish commander (Mustafa Kemal, the future Atatürk), Australian and New Zealand troops won a bridgehead at "Anzac Cove," north of Kaba Tepe, on the Aegean side of the peninsula, with some 20,000 men landing in the first two

days. The British, meanwhile, tried to land at five points around Cape Helles but established footholds only at three of them and then asked for reinforcements. Thereafter little progress was made, and the Turks took advantage of the British halt to bring into the peninsula as many troops as possible. The standstill of the enterprise led to a political crisis in London between Churchill, the Liberal government's first lord of the Admiralty, who, after earlier doubts, had made himself the foremost spokesman of the Dardanelles operation, and John, Lord Fisher, the first sea lord, who had always expressed doubts about it. Fisher demanded on May 14 that the operation be discontinued and, when he was overruled, resigned the next day. The Liberal government was replaced by a coalition, but Churchill, though relieved of his former post, remained in the War Council of the Cabinet.

The Churchill–Lord Fisher controversy

In July the British began sending five more divisions to the peninsula, and a new plan was hatched. In the hope of cutting the Turks' north–south communications down the peninsula by seizing the Sari Bair heights, which commanded the Straits from the west, the British reinforced the bridgehead at "Anzac Cove" and, in the night of August 6–7, landed more troops at Suvla Bay (Anafarta Limanı), farther to the north. Within a few days, both the offensive from "Anzac" and the new landing had proved ineffectual. More argument ensued in the War Council, and only late in the year was it acknowledged that the initially promising but ill-conducted enterprise should be given up. The evacuation of the troops was carried out from Suvla Bay and from "Anzac Cove" under cover of darkness in December 1915, and from the Cape Helles beaches in January 1916. The Dardanelles campaign thus came to a frustrating end. Had it succeeded it might well have ended Turkey's participation in the war. In failing, it had cost about 214,000 casualties and achieved nothing.

THE WESTERN AND EASTERN FRONTS, 1915

The Western Front, 1915. Repeated French attacks in February–March 1915 on the Germans' trench barrier in Champagne won only 500 yards (460 metres) of ground at a cost of 50,000 men. For the British, Sir Douglas Haig's 1st Army, between Armentières and Lens, tried a new experiment at Neuve-Chapelle on March 10, when its artillery opened an intense bombardment on a 2,000-yard front and then, after 35 minutes, lengthened its range, so that the attacking British infantry, behind the second screen of shells, could overrun the trenches ravaged by the first. But the experiment's immediate result was merely loss of life, both because shortage of munitions made the second barrage inadequate and because there was a five-hour delay in launching the infantry assault, against which the Germans, having overcome their initial surprise, had time to rally their resistance. It was clear to the Allies that this small-scale tactical experiment had missed success only by a narrow margin and that there was scope for its development. But the Allied commands missed the true lesson, which was that a surprise attack could be successfully made immediately following a short bombardment that compensated for its brevity by its intensity. Instead, they drew the superficial deduction that mere volume of shellfire was the key to reducing a trench line prior to an assault. Not until 1917 did they revert to the Neuve-Chapelle method. It was left to the Germans to profit from the experiment. In the meantime, a French offensive in April against the Germans' Saint-Mihiel salient, southeast of Verdun, sacrificed 64,000 men to no effect.

The Germans, in accordance with Falkenhayn's strategy, remained generally on the defensive in the West. They did, however, launch an attack on the Allies' Ypres salient (where the French had in November 1914 taken the place of the British). There, on April 22, 1915, they used chlorine gas for the first time on the Western Front, but they made the mistake of discharging it from cylinders (which were dependent on a favourable wind) rather than lobbing it onto the enemy trenches in artillery shells. The gas did throw the agonized defenders into chaotic flight; but the German high command, having been disappointed by the new weapon's performance under adverse conditions in Poland earlier in the year, had failed to provide ad-

Gas warfare at Ypres

equate reserves to exploit its unforeseen success. By the end of a month-long battle, the Allies' front was only slightly retracted.

On May 9, meanwhile, the Allies had launched yet another premature offensive, combining a major French onslaught between Lens and Arras with two thrusts by Haig's 1st Army, from Festubert and from Fromelles, against the Aubers Ridge north of Lens. The French prolonged their effort until June 18, losing 102,000 men without securing any gain; the British, still short of shells against the Germans' mass of machine guns, had suspended their attacks three weeks earlier.

An even worse military failure was the joint offensive launched by the Allies on Sept. 25, 1915. While 27 French divisions with 850 heavy guns attacked on a front 18 miles long in Champagne, north and east of Reims, simultaneous blows were delivered in distant Artois by 14 French divisions with 420 heavy guns on a 12-mile front south of Lens and by six British divisions with only 117 guns at Loos north of Lens. All of these attacks were disappointing failures, partly because they were preceded by prolonged bombardments that gave away any chance of surprise and allowed time for German reserves to be sent forward to close up the gaps that had been opened in the trench defenders' ranks by the artillery bombardment. At Loos the British use of chlorine gas was less effective than Haig had hoped, and his engagement of all his own available forces for his first assault came to nothing when his commander in chief, Sir John French, was too slow in sending up reserves; the French on both their fronts likewise lost, through lack of timely support, most of what they had won by their first attacks. In all, for a little ground, the Allies paid 242,000 men, against the defenders' loss of 141,000.

Having subsequently complained bitterly about Sir John French's management of operations, Haig was appointed British commander in chief in his place in December.

The Eastern Front, 1915. The Russians' plans for 1915 prescribed the strengthening of their flanks in the north and in Galicia before driving westward again toward Silesia. Their preparations for a blow at East Prussia's southern frontier were forestalled, as Ludendorff, striking suddenly eastward from East Prussia, enveloped four Russian divisions in the Augustów forests, east of the Masurian Lakes, in the second week of February; but in Galicia the winter's fighting culminated, on March 22, in the fall of Przemyśl to the Russians.

For the Central Powers, the Austrian spokesman, Conrad, primarily required some action to relieve the pressure on his Galician front, and Falkenhayn was willing to help him for that purpose without departing from his own general strategy of attrition—which was already coming into conflict with Ludendorff's desire for a sustained effort toward decisive victory over Russia. The plan finally adopted, with the aim of smashing the Russian centre in the Dunajec River sector of Galicia by an attack on the 18-mile front from Gorlice to Tuchów (south of Tarnów), was conceived with tactical originality: in order to maintain the momentum of advance, no daily objectives were to be set for individual corps or divisions; instead, each should make all possible progress before the Russians could bring their reserves up, on the assumption that the rapid advance of some attacking units would contagiously promote the subsequent advance of others that had at first met more resistance. Late in April, 14 divisions, with 1,500 guns, were quietly concentrated for the stroke against the six Russian divisions present. Mackensen was in command, with Hans von Seeckt, sponsor of the new tactic of infiltration, as his chief of staff.

The Dunajec–San offensive

The Gorlice attack was launched on May 2 and achieved success beyond all expectation. Routed on the Dunajec, the Russians tried to stand on the Wisłoka, then fell back again. By May 14, Mackensen's forces were on the San, 80 miles from their starting point, and at Jarosław they even forced a crossing of that river. Strengthened with more German troops from France, Mackensen then struck again, taking Przemyśl on June 3 and Lemberg (Lvov) on June 22. The Russian front was now bisected, but Falkenhayn and Conrad had foreseen no such result and

had made no preparations to exploit it promptly. Their consequent delays enabled the Russian armies to retreat without breaking up entirely.

Falkenhayn then decided to pursue a new offensive. Mackensen was instructed to veer northward, so as to catch the Russian armies in the Warsaw salient between his forces and Hindenburg's, which were to drive southeastward from East Prussia. Ludendorff disliked the plan as being too much of a frontal assault: the Russians might be squeezed by the closing-in of the two wings, but their retreat to the east would not be cut off. He once more urged his spring scheme for a wide enveloping maneuver through Kovno (Kaunas) on Vilna (Vilnius) and Minsk, in the north. Falkenhayn opposed this plan, fearing that it would mean more troops and a deeper commitment, and on July 2 the German emperor decided in favour of Falkenhayn's plan.

Ludendorff's doubts realized

The results justified Ludendorff's reservations. The Russians held Mackensen at Brest-Litovsk and Hindenburg on the Narew River long enough to enable the main body of their troops to escape through the unclosed gap to the east. Though by the end of August all of Poland had been occupied and 750,000 Russians had been taken prisoner in four months of fighting, the Central Powers had missed their opportunity to break Russia's ability to carry on the war.

Too late, Falkenhayn in September allowed Ludendorff to try what he had been urging much earlier, a wider enveloping movement to the north on the Kovno–Dvinsk–Vilna triangle. The German cavalry, in fact, approached the Minsk railway, far beyond Vilna; but the Russians' power of resistance was too great for Ludendorff's slender forces, whose supplies moreover began to run out, and by the end of the month his operations were suspended. The crux of this situation was that the Russian armies had been allowed to draw back almost out of the net before the long-delayed Vilna maneuver was attempted. Meanwhile, an Austrian attack eastward from Lutsk (Luck), begun later in September and continued into October, incurred heavy losses for no advantage at all. By October 1915 the Russian retreat, after a nerve-wracking series of escapes from the salients the Germans had systematically created and then sought to cut off, had come to a definite halt along a line running from the Baltic Sea just west of Riga southward to Czernowitz (Chernovtsy) on the Romanian border.

OTHER FRONTS, 1915–16

The Caucasus, 1914–16.   The Caucasian front between Russia and Turkey comprised two battlegrounds: Armenia in the west, Azerbaijan in the east. While the ultimate strategic objectives for the Turks were to capture the Baku oilfields in Azerbaijan and to penetrate Central Asia and Afghanistan in order to threaten British India, they needed first to capture the Armenian fortress of Kars, which, together with that of Ardahan, had been a Russian possession since 1878.

A Russian advance from Sarıkamış (Sarykamysh, south of Kars) toward Erzurum in Turkish Armenia in November 1914 was countered in December when the Turkish 3rd Army, under Enver himself, launched a three-pronged offensive against the Kars–Ardahan position. This offensive was catastrophically defeated in battles at Sarıkamış and at Ardahan in January 1915; but the Turks, ill-clad and ill-supplied in the Caucasian winter, lost many more men through exposure and exhaustion than in fighting (their 3rd Army was reduced in one month from 190,000 to 12,400 men, the battle casualties being 30,000). Turkish forces, which had meanwhile invaded neutral Persia's part of Azerbaijan and taken Tabriz on January 14, were expelled by a Russian counterinvasion in March.

Sarıkamış and Ardahan operations

During this campaign the Armenians had created disturbances behind the Turkish lines in support of the Russians and had threatened the already arduous Turkish communications. The Turkish government on June 11, 1915, decided to deport the Armenians. In the process of deportation, the Turkish authorities committed atrocities on a vast scale: Armenian deaths have been estimated at some 600,000. Subsequently, the Armenians perpetrated similar atrocities against the Turkish population of the Armenian country, but perforce on a smaller scale.

Grand Duke Nicholas, who had hitherto been commander in chief of all Russia's armies, was superseded by Emperor Nicholas himself in September 1915; the Grand Duke was then sent to command in the Caucasus. He and General N.N. Yudenich, the victor of Sarıkamış, started a major assault on Turkish Armenia in January 1916; Erzurum was taken on February 16, Trabzon on April 18, Erzincan on August 2; and a long-delayed Turkish counterattack was held at Oğnut. Stabilized to Russia's great advantage in the autumn, the new front in Armenia was thereafter affected less by Russo-Turkish warfare than by the consequences of revolution in Russia.

Mesopotamia, 1914–April 1916.   The British occupation of Basra, Turkey's port at the head of the Persian Gulf, in November 1914 had been justifiable strategically because of the need to protect the oil wells of southern Persia and the Abadan refinery. The British advance of 46 miles northward from Basra to al-Qurnah in December and the further advance of 90 miles up the Tigris to al-'Amārah in May–June 1915 ought to have been reckoned enough for all practical purposes, but the advance was continued in the direction of the fatally magnetic Baghdad, ancient capital of the Arab caliphs of Islām. Al-Kūt was occupied in September 1915, and the advance was pushed on until the British, under Major General Charles Townshend, were 500 miles away from their base at Basra. They fought a profitless battle at Ctesiphon, only 18 miles from Baghdad, on November 22 but then had to retreat to al-Kūt. There, from December 7, Townshend's 10,000 men were besieged by the Turks; and there, on April 29, 1916, they surrendered themselves into captivity.

The Egyptian frontiers, 1915–July 1917.   Even after the evacuation from Gallipoli, the British maintained 250,000 troops in Egypt. A major source of worry to the British was the danger of a Turkish threat from Palestine across the Sinai Desert to the Suez Canal. That danger waned, however, when the initially unpromising rebellion of the Hāshimite amir Husayn ibn 'Alī against the Turks in the Hejaz was developed by the personal enterprise of an unprofessional soldier of genius, T.E. Lawrence, into a revolt infecting the whole Arabian hinterland of Palestine and Syria and threatening to sever the Turks' vital Hejaz Railway (Damascus–Amman–Ma'ān–Medina). Sir Archibald Murray's British troops at last started a massive advance in December 1916 and captured some Turkish outposts on the northeastern edge of the Sinai Desert but made a pusillanimous withdrawal from Gaza in March 1917 at the very moment when the Turks were about to surrender the place to them; the attempt the next month to retrieve the mistake was repulsed with heavy losses. In June the command was transferred from Murray to Sir Edmund Allenby. In striking contrast to Murray's performance was Lawrence's capture of Aqaba (al-'Aqabah) on July 6, 1917: his handful of Arabs got the better of 1,200 Turks there.

The revolt of the Hejaz

Italy and the Italian front, 1915–16.   Great Britain, France, and Russia concluded on April 26, 1915, the secret Treaty of London with Italy, inducing the latter to discard the obligations of the Triple Alliance and to enter the war on the side of the Allies by the promise of territorial aggrandizement at Austria-Hungary's expense. Italy was offered not only the Italian-populated Trentino and Trieste but also South Tirol (to consolidate the Alpine frontier), Gorizia, Istria, and northern Dalmatia. On May 23, 1915, Italy accordingly declared war on Austria-Hungary.

The Italian commander, General Luigi Cadorna, decided to concentrate his effort on an offensive eastward from the province of Venetia across the comparatively low ground between the head of the Adriatic and the foothills of the Julian Alps; that is to say, across the lower valley of the Isonzo (Soča) River. Against the risk of an Austrian descent on his rear from the Trentino (which bordered Venetia to the northwest) or on his left flank from the Carnic Alps (to the north), he thought that limited advances would be precaution enough.

The Italians' initial advance eastward, begun late in May 1915, was soon halted, largely because of the flooding of the Isonzo, and trench warfare set in. Cadorna, however,

was determined to make progress and so embarked on a series of persistent renewals of the offensive, known as the Battles of the Isonzo. The first four of these (June 23–July 7; July 18–August 3; October 18–November 4; and November 10–December 2) achieved nothing worth the cost of 280,000 men; and the fifth (March 1916) was equally fruitless. The Austrians had shown on this front a fierce resolution that was often lacking when they faced the Russians. In mid-May 1916 Cadorna's program was interrupted by an Austrian offensive from the Trentino into the Asiago region of western Venetia. Though the danger of an Austrian breakthrough from the mountainous borderland into the Venetian plain in the rear of the Italians' Isonzo front was averted, the Italian counteroffensive in mid-June recovered only one-third of the territory overrun by the Austrians north and southwest of Asiago. The Sixth Battle of the Isonzo (August 6–17), however, did win Gorizia for the Italians. On August 28 Italy declared war on Germany. The next three months saw three more Italian offensives on the Isonzo, none of them really profitable. In the course of 1916 the Italians had sustained 500,000 casualties, twice as many as the Austrians, and were still on the Isonzo.

Serbia and the Salonika expedition, 1915–17. Austria's three attempted invasions of Serbia in 1914 had been brusquely repulsed by Serbian counterattacks. By the summer of 1915 the Central Powers were doubly concerned to close the account with Serbia, both for reasons of prestige and for the sake of establishing secure rail communications with Turkey across the Balkans. In August, Germany sent reinforcements to Austria's southern front; and, on Sept. 6, 1915, the Central Powers concluded a treaty with Bulgaria, whom they drew to their side by the offer of territory to be taken from Serbia. The Austro-German forces attacked southward from the Danube on October 6; and the Bulgars, undeterred by a Russian ultimatum, struck at eastern Serbia on October 11 and at Serbian Macedonia on October 14.

Bulgaria's entry into the war

The western Allies, surprised in September by the prospect of a Bulgarian attack on Serbia, hastily decided to send help through neutral Greece's Macedonian port of Salonika, relying on the collusion of Greece's pro-Entente prime minister, Eleuthérios Venizélos. Troops from Gallipoli, under the French general Maurice Sarrail, reached Salonika on October 5, but on that day Venizélos fell from power. The Allies advanced northward up the Vardar into Serbian Macedonia but found themselves prevented from junction with the Serbs by the westward thrust of the Bulgars. Driven back over the Greek frontier, the Allies were merely occupying the Salonika region by mid-December. The Serbian Army, meanwhile, to avoid double envelopment, had begun an arduous winter retreat westward over the Albanian mountains to refuge on the island of Corfu.

In the spring of 1916 the Allies at Salonika were reinforced by the revived Serbs from Corfu as well as by French, British, and some Russian troops, and the bridgehead was expanded westward to Vodena (Edessa) and eastward to Kilkis; but the Bulgars, who in May obtained Fort Rupel (Klidhi, on the Struma) from the Greeks, in mid-August not only overran Greek Macedonia east of the Struma but also, from Monastir (Bitola), invaded the Florina region of Greek Macedonia, to the west of the Allies' Vodena wing. The Allied counteroffensive took Monastir from the Bulgars in November 1916, but more ambitious operations, from March to May 1917, proved abortive. The Salonika front was tying down some 500,-000 Allied troops without troubling the Central Powers in any significant way.

The Western Front, 1916. In 1914 the centre of gravity of World War 1 had been on the Western Front, in 1915 it shifted to the Eastern, and in 1916 it once more moved back to France. Though the western Allies had dissipated some of their strength in the Dardanelles, Salonika, and Mesopotamia, the rising tide of Britain's new armies and of its increased munition supplies promised the means for an offensive far larger in scale than any before to break the trench deadlock. Britain's armies in France had grown

to 36 divisions by the end of 1915. By that time voluntary enlistments, though massive, had nevertheless proved to be inadequate to meet Britain's needs, so in January 1916, by the Military Service Act, voluntary service was replaced by conscription.

In December 1915 a conference of the leaders of the French, British, Belgian, and Italian armies, with representatives present from the Russian and Japanese armies, was held at Joffre's headquarters. They adopted the principle of a simultaneous general offensive in 1916 by France, Great Britain, Russia, and Italy. But military action by Germany was to dislocate this scheme, and only the British offensive came fully into operation.

Major campaigns on the Western Front, 1916.

By the winter of 1915–16, Falkenhayn regarded Russia as paralyzed and Italy as inconsiderable. He considered the time at last ripe for positive action against France, after whose collapse Great Britain would have no effective military ally on the European continent and would be brought to terms rather by submarine warfare than by land operations. For his offensive in the West, however, Falkenhayn clung always to his method of attrition. He believed that a mass breakthrough was unnecessary and that instead the Germans should aim to bleed France of its manpower by choosing a point of attack "for the retention of which the French Command would be compelled to throw in every man they have." The town of Verdun and its surrounding complex of forts was chosen, because it was a menace to the main German lines of communications, because it·was within a French salient and thus cramped the defenders, and because of the certainty that the French would sacrifice any number of men to defend Verdun for reasons of patriotism associated with the town itself.

The battle for Verdun

The keynote of Falkenhayn's tactical plan was to place a dense semicircle of German heavy and medium artillery to the north and east of Verdun and its outlying fortresses and then to stage a continuous series of limited infantry advances upon the forts. These advances would draw the French infantry into defending or trying to retake the forts, in the process of which they would be pulverized by

German artillery fire. In addition, each German infantry advance would have its way smoothed by a brief but extremely intense artillery bombardment that would clear the targeted ground of defenders.

Although French Intelligence had given early warnings of the Germans' offensive preparations, the French high command was so preoccupied with its own projected offensive scheme that the warning fell on deaf ears. At 7:15 AM on Feb. 21, 1916, the heaviest German artillery bombardment yet seen in the war began on a front of eight miles around Verdun, and the French trenches and barbed wire fields there were flattened out or upheaved in a chaos of tumbled earth. At 4:45 PM the German infantry advanced—although for the first day only on a front of two and a half miles. From then until February 24 the French defenders' lines east of the Meuse River crumbled away. Fort-Douaumont, one of the most important fortresses, was occupied by the Germans on February 25. By March 6, when the Germans began to attack on the west bank of the Meuse as well as on the east bank, the French had come to see that something more than a feint was intended. To relieve the pressure on France, the Russians made a sacrificial attack on the Eastern Front at Lake Naroch (see below); the Italians began their fifth offensive on the Isonzo (see above); and the British took over the Arras sector of the Western Front, thus becoming responsible for the whole line from the Yser southward to the Somme. Meanwhile, General Philippe Pétain was entrusted with commanding the defense of Verdun. He organized repeated counterattacks that slowed the German advance, and, more importantly, he worked to keep open the one road leading into Verdun that had not been closed by German shelling. This was the Bar-le-Duc road, which became known as La Voie Sacrée (the "Sacred Way") because vital supplies and reinforcements continued to be sent to the Verdun front along it despite constant harassment from the German artillery.

Slowly but steadily the Germans moved forward on Verdun: they took Fort-Vaux, southeast of Fort-Douaumont, on June 7 and almost reached the Belleville heights, the last stronghold before Verdun itself, on June 23. Pétain was preparing to evacuate the east bank of the Meuse when the Allies' offensive on the Somme River was at last launched. Thereafter, the Germans assigned no more divisions to the Verdun attack.

Preceded by a week's bombardment, which gave ample warning of its advent, the Somme offensive was begun on July 1, 1916, by the 11 British divisions of Rawlinson's new 4th Army on a 15-mile front between Serre, north of the Ancre, and Curlu, north of the Somme, while five French divisions attacked at the same time on an eight-mile front mainly south of the Somme, between Curlu and Péronne. With incredibly misplaced optimism, Haig had convinced himself that the British infantry would be able to walk forward irresistibly over ground cleared of defenders by the artillery. But the unconcealed preparations for the assault and the long preliminary bombardment had given away any chance of surprise, and the German defenders were well prepared for what was to come. In the event, the 60,000 attacking British infantrymen moving forward in symmetrical alignment at a snail's pace enforced by each man's 66 pounds (30 kilograms) of cumbrous equipment were mowed down in masses by the German machine guns, and the day's casualties were the heaviest ever sustained by a British army. The French participants in the attack had twice as many guns as the British and did better against a weaker system of defenses, but almost nothing could be done to exploit this comparative success.

Resigning himself now to limited advances, Haig concentrated his next effort on the southern sector of his Somme front. The Germans' second position there (Longueval, Bazentin, and Ovillers) fell on July 14, but again the opportunity of exploitation was missed. Thenceforward, at great cost in lives, a methodical advance was continued, gaining little ground but straining the German resistance. The first tanks to be used in the war, though in numbers far too small to be effective, were thrown into the battle by the British on September 15. In mid-November early rains halted operations. The four-month Battle of the Somme was a miserable failure except that it diverted German resources from the attack on Verdun. It cost the British 420,000 casualties, the French 195,000, and the Germans 650,000.

At Verdun, the summer slackening of German pressure enabled the French to organize counterattacks. Surprise attacks directed by General Robert-Georges Nivelle and launched by General Charles Mangin's army corps recovered Fort-Douaumont on October 24, Fort-Vaux on November 2, and places north of Douaumont in mid-December. Pétain's adroit defense of Verdun and these counterattacks had deprived Falkenhayn's offensive of its strategic fulfillment; but France had been so much weakened in the first half of 1916 that it could scarcely satisfy the Allies' expectations in the second. Verdun was one of the longest, bloodiest, and most ferocious battles of the war; French casualties amounted to about 400,000, German ones to about 350,000.

The Battle of Jutland. The summer of 1916 saw the long-deferred confrontation of Germany's High Seas Fleet and Great Britain's Grand Fleet in the Battle of Jutland—history's biggest naval battle, which both sides claimed as a victory.

Admiral Reinhard Scheer, who became commander in chief of the High Seas Fleet in January 1916, planned to contrive an encounter on the open sea between his fleet and some part of the British fleet in separation from the whole, so that the Germans could exploit their momentary superiority in numbers to achieve victory. Scheer's plan was to ensnare Admiral Beatty's squadron of battle cruisers at Rosyth, midway up Britain's eastern coast, by stratagem and destroy it before any reinforcements from the Grand Fleet's main base at Scapa Flow could reach it.

To set the trap, five battle cruisers of the German High Seas Fleet, together with four light cruisers, were to sail northward, under Hipper's command, from Wilhelmshaven, Ger., to a point off the southwestern coast of Norway. Scheer himself, with the battle squadrons of the High Seas Fleet, was to follow, 50 miles behind, to catch Beatty's forces in the gap once they had been lured eastward across the North Sea in pursuit of Hipper. But the signal for the German operation to begin, made in the afternoon of May 30, was intercepted and partially decoded by the British; and before midnight the whole British Grand Fleet was on its way to a rendezvous off Norway's southwestern coast and roughly across the planned route of the German fleet.

At 2:20 PM on May 31, when Admiral John Jellicoe's Grand Fleet squadrons from Scapa Flow were still 65 miles away to the north, Beatty's advance guard of light cruisers—five miles ahead of his heavier ships—and Hipper's scouting group learned quite accidentally of one another's proximity. An hour later the two lines were drawn up for battle, and in the next 50 minutes the British suffered severely, and the *Indefatigable* was sunk. When Beatty's battle cruisers came up, however, the German cruisers, in their turn, sustained such damage that Hipper sent in a protective screen of German destroyers in to launch a torpedo attack. The British had lost another battle cruiser, the *Queen Mary*, before the German High Seas Fleet was sighted by a British patrol to the south, at 4:35 PM. On this report Beatty ordered his ships northward, to lure the Germans toward the Grand Fleet under Jellicoe's command.

Not until 6:14 PM, after Jellicoe's squadrons and Beatty's had been within sight of one another for nearly a quarter of an hour, was the German fleet precisely located—only just in time for Jellicoe to deploy his ships to the best advantage. Jellicoe arrayed the Grand Fleet end-to-end in a line so that their combined broadsides could be brought to bear on the approaching German ships, who could in turn reply only with the forward guns of their leading ships. The British ships in effect formed the horizontal stroke and the German ships the vertical stroke of the letter "T," with the British having deployed into line at a right angle to the German ships' forward progress. This maneuver was in fact known as "crossing the enemy's T" and was the ideal situation dreamed of by the tacticians of both navies, since by "crossing the T" one's forces temporarily gained an overwhelming superiority of firepower.

The First Battle of the Somme

The German Trap

For the Germans this was a moment of unparalleled risk. Three factors helped prevent the destruction of the German ships in this trap: their own excellent construction, the steadiness and discipline of their crews, and the poor quality of the British shells. The *Lützow*, the *Derfflinger*, and the battleship *König* led the line and were under broadside fire from some 10 British battleships, yet their main guns remained undamaged and they fought back to such effect that one of their salvoes fell full on the *Invincible* and blew it up. This success, however, did little to relieve the intense bombardment from the other British ships, and the German fleet was still pressing forward into the steel trap of the Grand Fleet.

Relying on the magnificent seamanship of the German crews, Scheer extricated his fleet from the appalling danger into which it had run by a simple but, in practice, extremely difficult maneuver. At 6:30 PM he ordered a turn of 180° for all his ships at once; it was executed without collision; and the German battleships reversed course in unison and steamed out of the jaws of the trap, while German destroyers spread a smoke screen across their rear. The smoke and worsening visibility left Jellicoe in doubt about what had happened, and the British had lost contact with the Germans by 6:45 PM.

Yet the British Grand Fleet had maneuvered in such a way that it ended up between the German High Seas Fleet and the German ports, and this was the situation Scheer most dreaded, so at 6:55 PM Scheer ordered another reverse turn, perhaps hoping to pass around the rear of the British fleet. But the result for him was a worse position than that from which he had just escaped: his battle line had become compressed, and his leading ships found themselves again under intense bombardment from the broadside array of the British ships. Jellicoe had succeeded in crossing the Germans' "T" again. The *Lützow* now received irreparable damage, and many other German ships were damaged at this point. At 7:15 PM, therefore, to cause a diversion and win time, Scheer ordered his battle cruisers and destroyers ahead to virtually immolate themselves in a massed charge against the British ships.

This was the crisis of the Battle of Jutland. As the German battle cruisers and destroyers steamed forward, the German battleships astern became confused and disorganized in trying to execute their reverse turn. Had Jellicoe ordered the Grand Fleet forward through the screen of charging German battle cruisers at that moment, the fate of the German High Seas Fleet would likely have been sealed. As it was, fearing and overestimating the danger of torpedo attacks from the approaching destroyers, he ordered his fleet to turn away, and the two lines of battleships steamed apart at a speed of more than 20 knots. They did not meet again, and when darkness fell, Jellicoe could not be sure of the route of the German retreat. By 3:00 AM on June 1 the Germans had safely eluded their pursuers.

The British had sustained greater losses than the Germans in both ships and men. In all, the British lost three battle cruisers, three cruisers, eight destroyers, and 6,274 officers and men in the Battle of Jutland. The Germans lost one battleship, one battle cruiser, four light cruisers, five destroyers, and 2,545 officers and men. The losses inflicted on the British, however, were not enough to affect the numerical superiority of their fleet over the German in the North Sea, where their domination remained practically unchallengeable during the course of the war. Henceforth, the German High Seas Fleet chose not to venture out from the safety of its home ports.

The Eastern Front, 1916. In the hope of diverting German strength from the attack at Verdun on the Western Front, the Russians gallantly but prematurely opened an offensive north and south of Lake Naroch (Narocz, east of Vilna) on March 18, 1916, and continued it until March 27, though they won very little ground at great cost and only for a short time. They then reverted to preparations for a major offensive in July. The main blow, it was planned, should be delivered by A.E. Evert's central group of armies, assisted by an inward movement of A.N. Kuropatkin's army in the northern sector of the front. But at the same time, A.A. Brusilov's southwestern army group

was authorized to make a supposedly diversionary attack in its own sectors. In the event, Brusilov's attack became by far the more important operation of the offensive.

Surprised by the Austrians' Asiago offensive in May, Italy promptly appealed to the Russians for action to draw the enemy's reserves away from the Italian fronts, and the Russians responded by advancing their timetable again. Brusilov undertook to start his attack on June 4, on the understanding that Evert's should be launched 10 days later.

Thus began an offensive on the Eastern Front that was to be imperial Russia's last really effective military effort. Popularly known as Brusilov's offensive, it had such an astonishing initial success as to revive Allied dreams about the irresistible Russian "steamroller." Instead, its ultimate achievement was to sound the death knell of the Russian monarchy. Brusilov's four armies were distributed along a very wide front, with Lutsk at the northern end, Tarnopol and Buchach (Buczacz) in the central sector, and Czernowitz at the southern end. Having struck first in the Tarnopol and Czernowitz sectors on June 4, Brusilov on June 5 took the Austrians wholly by surprise when he launched A.M. Kaledin's army toward Lutsk: the defenses crumbled at once, and the attackers pushed their way between two Austrian armies. As the offensive was developed, the Russians were equally successful in the Buchach sector and in their thrust into Bukovina, which culminated in the capture of Czernowitz. By June 20, Brusilov's forces had captured 200,000 prisoners.

Evert and Kuropatkin, however, instead of striking in accordance with the agreed plan, found excuses for procrastination. The Russian chief of general staff, M.V. Alekseyev, therefore tried to transfer this inert couple's reserves to Brusilov, but the Russians' lateral communications were so poor that the Germans had time to reinforce the Austrians before Brusilov was strong enough to make the most of his victory. Though his forces in Bukovina advanced as far as the Carpathian Mountains, a counterstroke by Alexander von Linsingen's Germans in the Lutsk sector checked Russian progress at the decisive point. Further Russian drives from the centre of Brusilov's front were launched in July; but by early September the opportunity of exploiting the summer's victory was lost. Brusilov had driven the Austrians from Bukovina and from much of eastern Galicia and had inflicted huge losses of men and equipment on them, but he had depleted Russia's armies by about 1,000,000 men in doing so. (A large portion of this number consisted of deserters or prisoners.) This loss seriously undermined both the morale and the material strength of Russia. Brusilov's offensive also had indirect results of great consequence. First, it had compelled the Germans to withdraw at least seven divisions from the Western Front, where they could ill be spared from the Verdun and Somme battles. Second, it hastened Romania's unfortunate entry into the war.

Disregarding Romania's military backwardness, the Romanian government of Ionel Brătianu declared war against Austria-Hungary on Aug. 27, 1916. In entering the war, Romania succumbed to the Allies' offers of Austro-Hungarian territory and to the belief that the Central Powers would be too much preoccupied with other fronts to mount any serious riposte against a Romanian offensive. Some 12 of Romania's 23 divisions, in three columns, thus began on August 28 a slow westward advance across Transylvania, where at first there were only five Austro-Hungarian divisions to oppose them.

The riposte of the Central Powers was swifter than the progress of the invasion: Germany, Turkey, and Bulgaria declared war against Romania on August 28, August 30, and September 1, respectively; and Falkenhayn had plans already prepared. Though the miscarriage of his overall program for the year led to his being replaced by Hindenburg as chief of the German general staff on August 29, Falkenhayn's recommendation that Mackensen should direct a Bulgarian attack on southern Romania was approved; and Falkenhayn himself went to command on the Transylvanian front, for which five German as well as two more Austrian divisions were found available as reinforcements.

(margin notes:)
Brusilov's breakthrough

Romania's entry into the war

Mackensen's forces from Bulgaria stormed the Turtucaia (Tutrakan) bridgehead on the Danube southeast of Bucharest on September 5. His subsequent advance eastward into the Dobruja caused the Romanians to switch their reserves to that quarter instead of reinforcing their Transylvanian enterprise, which thereupon came to a halt. Falkenhayn soon attacked: first at the southern end of the 200-mile front, where he threw one of the Romanian columns back into the Roter Turm (Turnu Roşu) Pass, then in the centre, where by October 9 he had defeated another at Kronstadt (Braşov). For a month, however, the Romanians withstood Falkenhayn's attempts to drive them out of the Vulcan and Szurduk (Surduc) passes into Walachia. But just before winter snows blocked the way, the Germans took the two passes and advanced southward to Tirgu Jiu, where they won another victory. Then Mackensen, having turned westward from the Dobruja, crossed the Danube near Bucharest, on which his and Falkenhayn's armies converged. Bucharest fell on December 6, and the Romanian Army, a crippled force, could only fall back northeastward into Moldavia, where it had the belated support of Russian troops. The Central Powers had access to Romania's wheat fields and oil wells, and the Russians had 300 more miles of front to defend.

German strategy and the submarine war, 1916–January 1917. Both Admiral Scheer and General Falkenhayn doubted whether the German submarines could do any decisive damage to Great Britain so long as their warfare was restricted in deference to the protests of the United States; and, after a tentative reopening of the submarine campaign on Feb. 4, 1916, the German naval authorities in March gave the U-boats permission to sink without warning all ships except passenger vessels. The German civilian statesmen, however, who paid due attention to their diplomats' warnings about U.S. opinion, were soon able to prevail over the generals and the admirals: on May 4 the scope of the submarine campaign was again severely restricted.

The controversy between the statesmen and the advocates of unrestricted warfare was not dead yet. Hindenburg, chief of the general staff from August 29, had Ludendorff as his quartermaster general, and Ludendorff was quickly won over to supporting the chief of the Admiralty staff, Henning von Holtzendorff, in his arguments against the German chancellor, Theobald von Bethmann Hollweg, and the foreign minister, Gottlieb von Jagow. Whereas Bethmann and some other statesmen were hoping for a negotiated peace (see below), Hindenburg and Ludendorff were committed to a military victory. The British naval blockade, however, threatened to starve Germany into collapse before a military victory could be achieved, and soon Hindenburg and Ludendorff got their way: it was decided that, from Feb. 1, 1917, submarine warfare should be unrestricted and overtly so.

Declaration of unrestricted submarine warfare

Peace moves and U.S. policy to February 1917. There were few efforts by any of the Central or Allied Powers to achieve a negotiated peace in the first two years of the war. By 1916 the most promising signs for peace seemed to exist only in the intentions of two statesmen in power—the German chancellor Bethmann and the U.S. president Woodrow Wilson. Wilson, having proclaimed the neutrality of the United States in August 1914, strove for the next two years to maintain it. Early in 1916 he sent his confidant, Colonel Edward M. House, to sound London and Paris about the possibility of U.S. mediation between the belligerents. House's conversations with the British foreign secretary, Sir Edward Grey, resulted in the House–Grey Memorandum (Feb. 22, 1916), declaring that the United States might enter the war if Germany rejected Wilson's mediation but that Great Britain reserved the right to initiate U.S. mediatory action. By mid-1916, the imminent approach of the presidential election in the United States caused Wilson to suspend his moves for peace.

The Wilson–House overtures

In Germany, meanwhile, Bethmann had succeeded, with difficulty, in postponing the declaration of unrestricted submarine warfare. Wilson, though he was reelected president on Nov. 7, 1916, let another month pass without doing anything for peace, and during that period the German victory over Romania was taking place. Thus, while

Bethmann lost patience with waiting for Wilson to act, the German military leaders came momentarily to think that Germany, from a position of strength, might now propose a peace acceptable to themselves. Having been constrained to agree with the militarists that, if his proposals were rejected by the Allies, unrestricted submarine warfare should be resumed, Bethmann was allowed to announce, on December 12, the terms of a German offer of peace—terms, however, that were militarily so far-reaching as to preclude the Allies' acceptance of them. The main stumbling block was Germany's insistence upon its annexation of Belgium and of the occupied portion of northeastern France.

On Dec. 18, 1916, Wilson invited both belligerent camps to state their "war aims." The Allies were secretly encouraged by the U.S. secretary of state to offer terms too sweeping for German acceptance; and the Germans, suspecting collusion between Wilson and the Allies, agreed in principle to the opening of negotiations but left their statement of December 12 practically unchanged and privately decided that Wilson should not actually take part in any negotiation that he might bring about. By mid-January 1917 the December overtures had ended.

Strangely enough, Wilson's next appeal, a speech of Jan. 22, 1917, preaching international conciliation and a "peace without victory," elicited a confidential response from the British expressing readiness to accept his mediation. In the opposite camp, Austria-Hungary would likewise have listened readily to peace proposals, but Germany had already decided, on January 9, to declare unrestricted submarine warfare. Bethmann's message restating Germany's peace terms and inviting Wilson to persevere in his efforts was delivered on January 31 but was paradoxically accompanied by the announcement that unrestricted submarine warfare would begin the next day.

Wilson severed diplomatic relations between the United States and Germany on Feb. 3, 1917, and asked Congress, on February 26, for power to arm merchantmen and to take all other measures to protect U.S. commerce. But American opinion was still not ready for war, and the Germans wisely abstained from attacks on U.S. shipping. What changed the tenor of public feeling was the publication of the Zimmermann Telegram.

Arthur Zimmermann had succeeded Jagow as Germany's secretary of state for foreign affairs in November 1916; and in that same month the Mexican president, Venustiano Carranza, whose country's relations with the United States had been critical since March, had virtually offered bases on the Mexican coast to the Germans for their submarines. Zimmermann on Jan. 16, 1917, sent a coded telegram to his ambassador in Mexico instructing him to propose to the Mexican government that, if the United States should enter the war against Germany, Mexico should become Germany's ally with a view to recovering Texas, New Mexico, and Arizona from the United States. Intercepted and decoded by the British Admiralty Intelligence, this message was communicated to Wilson on February 24. It was published in the U.S. press on March 1, and it immediately set off a nationwide demand for war against Germany.

The Zimmermann Telegram

DEVELOPMENTS IN 1917

The Western Front, January–May 1917. The western Allies had good reason to be profoundly dissatisfied with the poor results of their enterprises of 1916, and this dissatisfaction was signalized by two major changes made at the end of the year. In Great Britain, the government of H.H. Asquith, already turned into a coalition in May 1915, was replaced in December 1916 by a coalition under David Lloyd George; and that same month in France the post of commander in chief of the army was transferred from Joffre to General R.-G. Nivelle.

As for the military situation, the fighting strength of the British Army on the Western Front had grown to about 1,200,000 men and was still growing. That of the French Army had been increased by the incorporation of colonial troops to some 2,600,000, so that, including the Belgians, the Allies disposed an estimated 3,900,000 men against 2,500,000 Germans. To the Allies, these figures suggested an offensive on their part.

Nivelle, who owed his appointment to the contrast between the brilliant success of his recent counterattacks at Verdun and the meagre results of Joffre's strategy of attrition, was deeply imbued with the optimism of which experience was by now curing Joffre. He also had ideas of national glory and, accordingly, modified plans made by Joffre in such a way as to assign to the French Army the determinant role in the offensive that, it was calculated, must decide the issue on the Western Front in 1917. Nivelle's plan in its final stage was that the British should make preparatory attacks not only north of the wilderness of the old Somme battlefields but also south of them (in the sector previously held by French troops); that these preparatory attacks should attract the German reserves; and, finally, that the French should launch the major offensive in Champagne (their forces in that sector having been strengthened both by new troops from the overseas colonies and by those transferred from the Somme). The tactics Nivelle planned to use were based on those he had employed so successfully at Verdun. But he placed an optimistic overreliance on his theory of combining "great violence with great mass," which basically consisted of intense artillery bombardments followed by massive frontal attacks.

Meanwhile, Ludendorff had foreseen a renewal of the Allied offensive on the Somme, and he used his time to frustrate Nivelle's plans and to strengthen the German front in two different ways. First, the hitherto rather shallow defenses in Champagne were by mid-February reinforced with a third line, out of range of the French artillery. Second, Ludendorff decided to anticipate the attack by falling back to a new and immensely strong line of defense. This new line, called the Siegfriedstellung, or "Hindenburg Line," was rapidly constructed across the base of the great salient formed by the German lines between Arras and Reims. From the German position east of Arras, the line ran southeastward and southward, passing west of Cambrai and Saint-Quentin to rejoin the old German line at Anizy (between Soissons and Laon). After a preliminary step backward on February 23, a massive withdrawal of all German troops from the westernmost bulges of the great salient to the new and shorter line was smoothly and quickly made on March 16. The major towns within the areas evacuated by the Germans (*i.e.*, Bapaume, Péronne, Roye, Noyon, Chauny, and Coucy) were abandoned to the Allies, but the area was left as a desert, with roads mined, trees cut down, wells fouled, and houses demolished, the ruins being strewn with explosive booby traps.

This baffling and unexpected German withdrawal dislocated Nivelle's plan, but, unperturbed by warnings from all quarters about the changed situation, Nivelle insisted *Nivelle's* on carrying it out. The Battle of Arras, with which the *offensive:* British started the offensive on April 9, 1917, began *Arras and* well enough for the attackers, thanks to much-improved *Cham-* artillery methods and to a new poison gas shell that par- *pagne* alyzed the hostile artillery. Vimy Ridge, at the northern end of the 15-mile battlefront, fell to the Canadian Corps, but the exploitation of this success was frustrated by the congestion of traffic in the British rear, and though the attack was continued until May 5, stiffer German resistance prevented exploitation of the advances made in the first five days.

Nivelle's own offensive in Champagne, launched on April 16 on the Aisne front from Vailly eastward toward Craonne and Reims, proved to be a fiasco. The attacking troops were trapped in a web of machine-gun fire, and by nightfall the French had advanced about 600 yards instead of the six miles anticipated in Nivelle's program. Only on the wings was any appreciable progress achieved. The results compared favourably with Joffre's offensives, as some 28,000 German prisoners were taken at a cost to the French of just under 120,000 casualties. But the effect on French morale was worse, because Nivelle's fantastic predictions of the offensive's success were more widely known than Joffre's had ever been. With the collapse of Nivelle's plan, his fortunes were buried in the ruins, and after some face-saving delay he was superseded as commander in chief by Pétain on May 15, 1917.

This change was made too late to avert a more harmful sequel, for in late April a mutiny broke out among the French infantry and spread until 16 French army corps were affected. The authorities chose to ascribe it to seditious propaganda, but the mutinous outbreaks always occurred when exhausted troops were ordered back into the line, and they signaled their grievances by such significant cries as: "We'll defend the trenches, but we won't attack." Pétain restored tranquillity by meeting the just grievances of the troops; his reputation for sober judgment restored the troops' confidence in their leaders, and he made it clear that he would avoid future reckless attacks on the German lines. But the military strength of France could never be fully restored during the war.

Pétain insisted that the only rational strategy was to keep to the defensive until new factors had changed the conditions sufficiently to justify taking the offensive with a reasonable hope of success. His constant advice was: "We must wait for the Americans and the tanks." Tanks were now being belatedly built in large numbers, and this emphasis on them showed a dawning recognition that machine warfare had superseded mass infantry warfare.

The U.S. entry into the war. After the rupture of diplomatic relations with Germany on Feb. 3, 1917, events pushed the United States inexorably along the road to war. Using his authority as commander in chief, Wilson on March 9 ordered the arming of American merchant ships so that they could defend themselves against U-boat attacks. German submarines sank three U.S. merchant ships during March 16–18 with heavy loss of life. Supported by his Cabinet, by most newspapers, and by a large segment of public opinion, Wilson made the decision on March 20 for the United States to declare war on Germany, and on March 21 he called Congress to meet in special session on April 2. He delivered a ringing war message to that body, and the war resolution was approved by the Senate on April 3 and by the House of Representatives on April 6. The presidential declaration of war followed immediately.

The entry of the United States was the turning point of the war, because it made the eventual defeat of Germany possible. It had been foreseen in 1916 that if the United States went to war, the Allies' military effort against Germany would be upheld by U.S. supplies and by enormous extensions of credit. These expectations were amply and decisively fulfilled. The United States' production of armaments was to meet not only its own needs but also France's and Great Britain's. In this sense, the American economic contribution alone was decisive. By April 1, 1917, the Allies had exhausted their means of paying for essential supplies from the United States, and it is difficult to see how they could have maintained the war effort if the United States had remained neutral. American loans to the Allies worth $7,000,000,000 between 1917 and the end of the war maintained the flow of U.S. arms and food across the Atlantic.

The American military contribution was as important as the economic one. A system of conscription was introduced by the Selective Service Act of May 18, 1917, but many months were required for the raising, training, and dispatch to Europe of an expeditionary force. There were still only 85,000 U.S. troops in France when the Germans launched their last great offensive in March 1918; but there were 1,200,000 there by the following September. The U.S. commander in Europe was General John J. Pershing.

The U.S. Navy was the second largest in the world when America entered the war in 1917. The Navy soon abandoned its plans for the construction of battleships and instead concentrated on building the destroyers and submarine chasers so desperately needed to protect Allied shipping from the U-boats. By July 1917 there were already 35 U.S. destroyers stationed at Queenstown (Cobh) on the coast of Ireland—enough to supplement British destroyers for a really effective transatlantic convoy system. By the end of the war there were more than 380 U.S. craft stationed overseas.

The U.S. declaration of war also set an example to other states in the Western Hemisphere. Cuba, Panama, Haiti, Brazil, Guatemala, Nicaragua, Costa Rica, and

Honduras were all at war with Germany by the end of July 1918, while the Dominican Republic, Peru, Uruguay, and Ecuador contented themselves with the severance of relations.

The Russian revolutions and the Eastern Front, March 1917–March 1918. The Russian Revolution of March (February, old style) 1917 put an end to the autocratic monarchy of imperial Russia and replaced it with a provisional government. But the latter's authority was at once contested by soviets, or "councils of workers' and soldiers' deputies," who claimed to represent the masses of the people and so to be the rightful conductors of the revolution. The March Revolution was an event of tremendous magnitude. Militarily it appeared to the western Allies as a disaster and to the Central Powers as a golden opportunity. The Russian Army remained in the field against the Central Powers, but its spirit was broken, and the Russian people were utterly tired of a war that the imperial regime for its own reasons had undertaken without being morally or materially prepared for it. The Russian Army had been poorly armed, poorly supplied, poorly trained, and poorly commanded and had suffered a long series of defeats. The soviets' propaganda—including the notorious Order No. 1 of the Petrograd Soviet (March 14, 1917), which called for committees of soldiers and sailors to take control of their units' arms and to ignore any opposition from their officers—served to subvert the remnants of discipline in troops who were already deeply demoralized.

But the leaders of the provisional government foresaw that a German victory in the war would bode ill for Russia in the future, and they were also conscious of their nation's obligations toward the western Allies. A.F. Kerensky, minister of war from May 1917, thought that a victorious offensive would enhance the new government's authority, besides relieving pressure on the Western Front. The offensive, however, which General L.G. Kornilov launched against the Austrians in eastern Galicia on July 1, 1917, was brought to a sudden halt by German reinforcements after 10 days of spectacular advances, and it turned into a catastrophic rout in the next three weeks. By October the advancing Germans had won control of most of Latvia and of the approaches to the Gulf of Finland.

Meanwhile, anarchy was spreading over Russia. The numerous non-Russian peoples of the former empire were one after another claiming autonomy or independence from Russia—whether spontaneously or at the prompting of the Germans in occupation of their countries. Finns, Estonians, Latvians, Lithuanians, and Poles were, by the end of 1917, all in various stages of the dissidence from which the independent states of the postwar period were to emerge; and, at the same time, Ukrainians, Georgians, Armenians, and Azerbaijanis were no less active in their own nationalist movements.

The provisional government's authority and influence were rapidly fading away in Russia proper during the late summer and autumn of 1917. The Bolshevik Revolution of November (October, O.S.) 1917 overthrew the provisional government and brought to power the Marxist Bolsheviks under the leadership of Vladimir I. Lenin. The Bolshevik Revolution spelled the end of Russia's participation in the war. Lenin's decree on land, of November 8, undermined the Eastern Front by provoking a homeward rush of soldiers anxious to profit from the expropriation of their former landlords. On November 8, likewise, Lenin issued his decree on peace, which offered negotiations to all belligerents but precluded annexations and indemnities and stipulated a right of self-determination for all peoples concerned. Finally, on November 26, the new Bolshevik government unilaterally ordered a cessation of hostilities both against the Central Powers and against the Turks.

An armistice between Lenin's Russia and the Central Powers was signed at Brest-Litovsk on Dec. 15, 1917. The ensuing peace negotiations were complicated: on the one hand, Germany wanted peace in the east in order to be free to transfer troops thence to the Western Front, but Germany was at the same time concerned to exploit the principle of national self-determination in order to transfer as much territory as possible into its own safe orbit from that of revolutionary Russia. On the other hand, the

Bolsheviks wanted peace in order to be free to consolidate their regime in the east with a view to being able to extend it westward as soon as the time should be ripe. When the Germans, despite the armistice, invaded the Ukraine to cooperate with the Ukrainian nationalists against the Bolsheviks there and furthermore resumed their advance in the Baltic countries and in Belorussia, Lenin rejected his colleague Leon Trotsky's stopgap policy ("neither peace nor war") and accepted Germany's terms in order to save the Bolshevik Revolution. By the Treaty of Brest-Litovsk (March 3, 1918), Soviet Russia recognized Finland and the Ukraine as independent; renounced control over Estonia, Latvia, Lithuania, Poland, and most of Belorussia; and ceded Kars, Ardahan, and Batumi to Turkey.

Greek affairs. Greece's attitude toward the war was long uncertain: whereas King Constantine I and the general staff stood for neutrality, Eleuthérios Venizélos, leader of the Liberal Party, favoured the Allied cause. As prime minister from 1910, Venizélos wanted Greece to participate in the Allies' Dardanelles enterprise against Turkey in 1915, but his arguments were overruled by the general staff. The Allies occupied Lemnos and Lesbos regardless of Greece's neutrality. Constantine dismissed Venizélos from office twice in 1915, but Venizélos still commanded a majority in Parliament. The Bulgarians' occupation of Greek Macedonia in summer 1916 provoked another political crisis. Venizélos left Athens for Crete late in September, set up a government of his own there, and transferred it early in October to Salonika. On November 27 it declared war on Germany and Bulgaria. Finally, the Allies, on June 11, 1917, deposed King Constantine. Venizélos then returned to Athens to head a reunified Greek government, which on June 27 declared war on the Central Powers.

Caporetto. On the Italian front, Cadorna's 10th Battle of the Isonzo in May–June 1917 won very little ground; but his 11th, from August 17 to September 12, during which General Luigi Capello's 2nd Army captured much of the Bainsizza Plateau (Banjška Planota), north of Gorizia, strained Austrian resistance very severely. To avert an Austrian collapse, Ludendorff decided that the Austrians must take the offensive against Italy and that he could, with difficulty, lend them six German divisions for that purpose.

The offensive was boldly planned, very ably organized, and well executed. While two Austrian armies, under General Svetozar Borojević von Bojna, attacked the eastern end of the Italians' Venetian salient on the Bainsizza Plateau and on the low ground near the Adriatic shore, the German 14th Army, comprising the six German divisions and nine Austrian ones under Otto von Below, with Konrad Krafft von Dellmensingen as his chief of staff, on Oct. 24, 1917, began to force its way over the barrier of the Julian Alps at the northeastern corner of the Venetian salient, with Caporetto approximately opposite the middle point of the line. The Italians, completely surprised by this thrust, which threatened their forces both to the north and to the south, fell back in confusion: Below's van reached Udine, the former site of the Italian general headquarters, by October 28 and was on the Tagliamento River by October 31. Below's success had far exceeded the hopes of the planners of the offensive, and the Germans could not exploit their speedy advance as effectively as they wished. Cadorna, with his centre shattered, managed by precipitate retreat to save the wings of his army and was able, by November 9, to rally his remaining 300,000 troops behind the Piave River, north of Venice. The Italians had sustained about 500,000 casualties, and 250,000 more had been taken prisoner. General Armando Diaz was then appointed commander in chief in Cadorna's place. The Italians managed to hold the Piave front against direct assaults and against attempts to turn its left flank by an advance from the Trentino. The Italians' defense was helped by British and French reinforcements that had been rushed to Italy when the collapse began. A conference of the military and political leaders of the Allies was held at Rapallo in November, and out of this conference there sprang the joint Supreme War Council at Versailles, and ultimately a unified military command.

Mesopotamia, summer 1916–winter 1917. The British

forces in Mesopotamia, neglected hitherto and discouraged by the disaster at al-Kūt (see above), received better attention from London in the second half of 1916; and Sir Frederick Stanley Maude, who became commander in chief in August, did so much to restore their morale that by December he was ready to undertake the recapture of al-Kūt as a first step toward capturing Baghdad.

By a series of outflanking movements, the British made their way gradually and methodically up the Tigris, compelling the Turks to extend their defenses upstream. When the final blow at al-Kūt was delivered by a frontal attack on Feb. 22, 1917, British forces were already crossing the river from the west bank behind the town; but though al-Kūt fell two days later most of the Turkish garrison extricated itself from the threatened encirclement. Unable to hold a new line on the Diyālā River, the Turkish commander, Kâzim Karabekir, evacuated Baghdad, which the British entered on March 11. In September the British position in Baghdad was definitively secured by the capture of ar-Ramādī, on the Euphrates about 60 miles to the west; and early in November the main Turkish force in Mesopotamia was driven from Tikrīt, on the Tigris midway between Baghdad and Mosul.

The capture of Baghdad

Maude, having within a year changed the Mesopotamian scene from one of despair to one of victory, died of cholera on Nov. 18, 1917. His successor in command was Sir William Marshall.

Palestine, autumn 1917. Having assumed command in Egypt (see above), Allenby transferred his headquarters from Cairo to the Palestinian front and devoted the summer of 1917 to preparing a serious offensive against the Turks. On the Turkish side, Falkenhayn, now in command at Aleppo, was at this time himself planning a drive into the Sinai Peninsula for the autumn, but the British were able to strike first.

The Turkish front in southern Palestine extended from Gaza, on the coast, southeastward to Abu Hureira (Tel Haror) and thence to the stronghold of Beersheba. To disguise his real intention of achieving a breakthrough at Abu Hureira, for which, however, the capture of Beersheba was obviously prerequisite, Allenby began his operation with a heavy bombardment of Gaza from October 20 onward. When Beersheba had been seized by converging movements on October 31, a feint attack on Gaza was launched next day to draw the Turkish reserves thither. Then, the main attack, delivered on November 6, broke through the weakened defenses at Abu Hureira and into the plain of Philistia. Falkenhayn had attempted a counterstroke at Beersheba, but the collapse of the Turkish centre necessitated a general retreat. By November 14 the Turkish forces were split in two divergent groups, the port of Jaffa was taken, and Allenby wheeled his main force to the right for an advance inland on Jerusalem. On December 9 the British occupied Jerusalem.

The Western Front, June–December 1917. Pétain's decision to remain temporarily on the defensive after Nivelle's failure gave Haig the opportunity to fulfill his desire for a British offensive in Flanders. He took the first step on June 7, 1917, with a long-prepared attack on the Messines Ridge, north of Armentières, on the southern flank of his Ypres salient. This attack by General Sir Herbert Plumer's 2nd Army proved an almost complete success; it owed much to the surprise effect of 19 huge mines simultaneously fired after having been placed at the end of long tunnels under the German front lines. The capture of the ridge inflated Haig's confidence; and, though General Sir Hubert Gough, in command of the 5th Army, advocated a step-by-step method for the offensive, Haig committed himself to Plumer's view that they "go all out" for an early breakthrough. Haig disregarded the well-founded forecast that, from the beginning of August, rain would be turning the Flanders countryside into an almost impassable swamp. The Germans, meanwhile, were well aware that an offensive was coming from the Ypres salient: the flatness of the plain prevented any concealment of Haig's preparations, and a fortnight's intensive bombardment (4,500,000 shells from 3,000 guns) served to underline the obvious—without, however, destroying the German machine gunners' concrete pillboxes.

Thus, when the Third Battle of Ypres was begun, on July 31, only the left wing's objectives were achieved: on the crucial right wing the attack was a failure. Four days later, the ground was already swampy. When the attack was resumed on August 16, very little more was won, but Haig was still determined to persist in his offensive. Between September 20 and October 4, thanks to an improvement in the weather, the infantry was able to advance into positions cleared by bombardment, but no farther. Haig launched another futile attack on October 12, followed by three more attacks, scarcely more successful, in the last 10 days of October. At last, on November 6, when his troops advanced a very short distance and occupied the ruins of Passchendaele (Passendale), barely five miles beyond the starting point of his offensive, Haig felt that enough had been done. Having prophesied a decisive success without "heavy losses," he had lost 325,000 men and inflicted no comparable damage on the Germans.

The Third Battle of Ypres

Pétain, less pretentious and merely testing what might be done with his rehabilitated French Army, had at least as much to show for himself as Haig. In August the French 2nd Army under General M.-L.-A. Guillaumat fought the last battle of Verdun, winning back all the remainder of what had been lost to the Germans in 1916. In October General P.-A.-M. Maistre's 10th Army, in the Battle of Malmaison, took the ridge of the Chemin des Dames, north of the Aisne to the east of Soissons, where the front in Champagne joined the front in Picardy south of the Somme.

The British, at least, closed the year's campaign with an operation of some significance for the future. When the offensive from Ypres died out in the Flanders mud, they looked again at their tanks, of which they now had a considerable force but which they could hardly use profitably in the swamps. A Tank Corps officer, Colonel J.F.C. Fuller, had already suggested a large-scale raid on the front southwest of Cambrai, where a swarm of tanks, unannounced by any preparatory bombardment, could be released across the rolling downland against the German trenches. This comparatively modest scheme might have been wholly successful if left unchanged, but the British command transformed it: Sir Julian Byng's 3rd Army was to actually try to capture Cambrai and to push on toward Valenciennes. On November 20, therefore, the attack was launched, with 324 tanks leading Byng's six divisions. The first massed assault of tanks in history took the Germans wholly by surprise, and the British achieved a far deeper penetration and at less cost than in any of their past offensives. Unfortunately, however, all of Byng's troops and tanks had been thrown into the first blow, and, as he was not reinforced in time, the advance came to a halt several miles short of Cambrai. A German counterstroke, on November 30, broke through on the southern flank of the new British salient and threatened Byng's whole army with disaster before being checked by a further British counterattack. In the end, three-quarters of the ground that the British had won was reoccupied by the Germans. Even so, the Battle of Cambrai had proved that surprise and the tank in combination could unlock the trench barrier.

Cambrai

The Far East. China's entry into the war in 1917 on the side of the Allies was motivated not by any grievance against the Central Powers but by the Peking government's fear lest Japan, a belligerent since 1914, should monopolize the sympathies of the Allies and of the United States when Far Eastern affairs came up for settlement after the war. Accordingly, in March 1917 the Peking government severed its relations with Germany; and on August 14 China declared war not only on Germany but also on the western Allies' other enemy, Austria-Hungary. China's contribution to the Allied war effort was to prove negligible in practical effects, however.

Naval operations, 1917–18. Since Germany's previous restrictions of its submarine warfare had been motivated by fear of provoking the United States into war, the U.S. declaration of war in April 1917 removed any reason for the Germans to retreat from their already declared policy of unrestricted warfare. Consequently, the U-boats, having sunk 181 ships in January, 259 in February, and 325 in March, sank 430 in April. The April sinkings

represented 852,000 gross tons, to be compared both with the 600,000 postulated by the German strategists as their monthly target and with the 700,000 that the British in March had pessimistically foretold for June. The Germans had calculated that if the world's merchant shipping could be sunk at the monthly rate of 600,000 tons, the Allies, being unable to build new merchant ships fast enough to replace those lost, could not carry on the war for more than five months. At the same time, the Germans, who had 111 U-boats operational when the unrestricted campaign began, had embarked on an extensive building program that, when weighed against their current losses of one or two U-boats per month, promised a substantial net increase in the U-boats' numbers. During April, one in every four of the merchant ships that sailed from British ports was destined to be sunk, and by the end of May the quantity of shipping available to carry the vital foodstuffs and munitions to Great Britain had been reduced to only 6,000,000 tons.

The April total, however, proved to be a peak figure— The con- primarily because the Allies at last adopted the convoy voy system system for the protection of merchant ships. Previously, a ship bound for one of the Allies' ports had set sail by itself as soon as it was loaded. The sea was thus dotted with single and unprotected merchant ships, and a scouting U-boat could rely on several targets coming into its range in the course of a cruise. The convoy system remedied this by having groups of merchant ships sail within a protective ring of destroyers and other naval escorts. It was logistically possible and economically worthwhile to provide this kind of escort for a group of ships. Furthermore, the combination of convoy and escort would force the U-boat to risk the possibility of a counterattack in order to sink the merchant ships, thus giving the Allies a prospect of reducing the U-boats' numbers. Despite the manifest and seemingly overwhelming benefits of the convoy system, the idea was novel and, like any untried system, met with powerful opposition from within the military. It was only in the face of extreme necessity and under great pressure from Lloyd George that the system was tried, more or less as a last resort.

The first convoy sailed from Gibraltar to Great Britain on May 10, 1917; the first from the United States sailed later in May; ships using the South Atlantic sailed in convoy from July 22. During the later months of 1917 the use of convoys caused an abrupt fall in the sinkings by U-boats: 500,500 tons in May, 300,200 in September, and only about 200,600 in November. The convoy system was so quickly vindicated that in August it was extended to shipping outward-bound from Great Britain. The Germans themselves soon observed that the British had grasped the principles of antisubmarine warfare, and that sailing ships in convoys considerably reduced the opportunities for attack.

Apart from the convoys, the Allies improved their antisubmarine technology (hydrophones, depth charges, etc.) and extended their minefields. In 1918, moreover, Admiral Sir Roger Keyes, in command at Dover, set up a system whereby the English Channel was patrolled by surface craft with searchlights, so that U-boats passing through it had to submerge themselves to depths at which they were liable to strike the mines that had been laid for them. Subsequently, most of the U-boats renounced the Channel as a way into the Atlantic and instead took the passage north of Great Britain, thus losing precious fuel and time before reaching the heavily traveled sea lanes of the western approaches to Great Britain. In the summer of 1918, U.S. minelayers laid more than 60,000 mines (13,000 of them British) in a wide belt across 180 miles of the North Sea between Scotland and Norway, so as to obstruct the U-boats' only access from Germany to the Atlantic other than the closely guarded Channel.

The cumulative effect of all these measures was the gradual containment and ultimately the defeat of the U-boat campaign, which never again achieved the success of April 1917. While sinkings by submarines, after that month, steadily fell, the losses of U-boats showed a slow but steady rise, and more than 40 were destroyed in the first six months of 1918. At the same time the replacement of mer-

chant vessels in the building program improved steadily, until it eventually far outstripped losses. In October 1918, for example, 511,000 tons of new Allied merchant ships were launched, while only 118,559 tons were lost.

Air warfare. At the start of the war the land and sea forces used the aircraft put at their disposal primarily for reconnaissance, and air fighting began as the exchange of shots from small arms between enemy airmen meeting one another in the course of reconnoitering. Fighter aircraft armed with machine guns, however, made their appearance in 1915. Tactical bombing and the bombing of enemy air bases were also gradually introduced at this time. Contact patrolling, with aircraft giving immediate support to infantry, was developed in 1916.

Strategic bombing, on the other hand, was initiated early   Strategic enough: British aircraft from Dunkirk bombed Cologne,   bombing Düsseldorf, and Friedrichshafen in the autumn of 1914, their main objective being the sheds of the German dirigible airships, or Zeppelins; and raids by German airplanes or seaplanes on English towns in December 1914 heralded a great Zeppelin offensive sustained with increasing intensity from January 1915 to September 1916 (London was first bombed in the night of May 31–June 1, 1915). In October 1916 the British, in turn, began a more systematic offensive, from eastern France, against industrial targets in southwestern Germany.

While the British directed much of their new bombing strength to attacks on the bases of the U-boats, the Germans used theirs largely to continue the offensive against the towns of southeastern England. On June 13, 1917, in daylight, 14 German bombers dropped 118 high explosive bombs on London and returned home safely. This lesson and that of subsequent raids by the German Gotha bombers made the British think more seriously about strategic bombing and about the need for an air force independent of the other fighting services. The Royal Air Force (RAF), the world's first separate air service, was brought into active existence by a series of measures taken between October 1917 and June 1918.

Peace moves, March 1917–September 1918. Until the end of 1916, the pursuit of peace was confined to individuals and to small groups. In the following months it began to acquire a broad popular backing. Semi-starvation in towns, mutinies in the armies, and casualty lists that seemed to have no end made more and more people question the need and the wisdom of continuing the war.

Francis Joseph, Austria's venerable old emperor, died on Nov. 21, 1916. The new emperor, Charles I, and his foreign minister, Graf Ottokar Czernin, initiated peace moves in the spring of 1917 but unfortunately did not concert their diplomatic efforts, and the channels of negotiation they opened between Austria-Hungary and the Allies had dried up by that summer.

In Germany, Matthias Erzberger, a Roman Catholic member of the Reichstag, had, on July 6, 1917, proposed that territorial annexations be renounced in order to facilitate a negotiated peace. During the ensuing debates Bethmann Hollweg resigned the office of chancellor, and the emperor William II appointed the next chancellor, Ludendorff's nominee Georg Michaelis, without consulting the Reichstag. The Reichstag, offended, proceeded to pass its *Friedensresolution,* or "peace resolution," of July 19 by 212 votes. The peace resolution was a string of innocuous phrases expressing Germany's desire for peace but without a clear renunciation of annexations or indemnities. The Allies took almost no notice of it.

Erzberger's proposal of July 6 had been intended to pave the way for Pope Benedict XV's forthcoming note to the belligerents of both camps. Dated Aug. 1, 1917, this note advocated a German withdrawal from Belgium and from France, the Allies' withdrawal from the German colonies, and the restoration not only of Serbia, Montenegro, and Romania but also of Poland to independence. France and Great Britain declined to give an express reply pending Germany's statement of its attitude about Belgium, on which Germany avoided committing itself.

An unofficial peace move was made in London: on Nov. 29, 1917, the *Daily Telegraph* published a letter from Lord Lansdowne suggesting negotiations on the basis of

the status quo antebellum. Lloyd George rejected Lansdowne's theses on December 14.

The U.S. president Woodrow Wilson made himself the chief formulator and spokesman of the war aims of the Allies and the United States. The first nine months of 1918 saw Wilson's famous series of pronouncements on his war aims: the Fourteen Points (January 8), the "Four Principles" (February 11), the "Four Ends" (July 4), and the "Five Particulars" (September 27). Most important, not least because of Germany's deluded reliance on them in its eventual suing for peace, were the Fourteen Points: (1) open covenants of peace and the renunciation of secret diplomacy, (2) freedom of navigation on the high seas in wartime as well as peace, (3) the maximum possible freedom of trade, (4) a guaranteed reduction of armaments, (5) an impartial colonial settlement accommodating not only the colonialist powers but also the peoples of the colonies, (6) the evacuation of all Russian territory and respect for Russia's right of self-determination, (7) the complete restoration of Belgium, (8) a complete German withdrawal from France and satisfaction for France about Alsace-Lorraine, (9) a readjustment of Italy's frontiers on an ethnic basis, (10) an open prospect of autonomy for the peoples of Austria-Hungary, (11) the restoration of Romania, Serbia, and Montenegro, with free access to the sea for Serbia and international guarantees of the Balkan states' independence and integrity, (12) the prospect of autonomy for non-Turkish peoples of the Ottoman Empire and the unrestricted opening of the Straits, but secure sovereignty for the Turks in their own areas, (13) an independent Poland with access to the sea and under international guarantee, and (14) "a general association of nations," to guarantee the independence and integrity of all states, great and small. The three subsequent groups of pronouncements mainly consisted of idealistic expansions of themes implicit in the Fourteen Points, with increasing emphasis on the wishes of subject populations; but the first of the "Four Ends" was that every arbitrary power capable by itself of disturbing world peace should be rendered innocuous.

Wilson's peace campaign was a significant factor in the collapse of the will to fight of the German people and the decision of the German government to sue for peace in October 1918. Indeed, the Germans conducted their preliminary peace talks exclusively with Wilson. And the Armistice, when it came on Nov. 11, 1918, was formally based upon the Fourteen Points and additional Wilsonian pronouncements, with two reservations by the British and French relating to freedom of the seas and reparations.

The last offensives and the Allies' victory

THE WESTERN FRONT, MARCH–SEPTEMBER 1918

As the German strength on the Western Front was being steadily increased by the transfer of divisions from the Eastern Front (where they were no longer needed since Russia had withdrawn from the war), the Allies' main problem was how to withstand an imminent German offensive pending the arrival of massive reinforcements from the United States. Eventually Pétain persuaded the reluctant Haig that the British with 60 divisions should extend their sector of the front from 100 to 125 miles as compared with the 325 miles to be held by the French with approximately 100 divisions. Haig thus devoted 46 of his divisions to the front from the Channel to Gouzeaucourt (southwest of German-held Cambrai) and 14 to the remaining third of the front from Gouzeaucourt past German-held Saint-Quentin to the Oise River.

On the German side, between Nov. 1, 1917, and March 21, 1918, the German divisions on the Western Front were increased from 146 to 192, the troops being drawn from Russia, Galicia, and Italy. By these means the German armies in the west were reinforced by a total of about 570,000 men. Ludendorff's interest was to strike from his temporary position of strength—before the arrival of the major U.S. contingents—and at the same time to ensure that his German offensive should not fail for the same reasons as the Allies' offensives of the past three years. Accordingly he formed an offensive strategy based

(margin: Wilson's Fourteen Points)

on taking the tactical line of least resistance. The main German attacks would begin with brief but extremely intense artillery bombardments using a high proportion of poison gas and smoke shells. These would incapacitate the Allies' forward trenches and machine-gun emplacements and would obscure their observation posts. Then a second and lighter artillery barrage would begin to creep forward over the Allied trenches at a walking pace (in order to keep the enemy under fire), with the masses of German assault infantry advancing as closely as possible behind it. The key to the new tactics was that the assault infantry would bypass machine-gun nests and other points of strong resistance instead of waiting, as had been the previous practice on both sides, for reinforcements to mop up the obstructions before continuing the advance. The Germans would instead continue to advance in the direction of the least enemy resistance. The mobility of the German advance would thus be assured, and its deep infiltration would result in large amounts of territory being taken.

Such tactics demanded exceptionally fit and disciplined troops and a high level of training. Ludendorff accordingly drew the best troops from all the Western Front forces at his disposal and formed them into elite shock divisions. The troops were systematically trained in the new tactics, and every effort was also made to conceal the actual areas at which the German main attacks would be made.

Ludendorff's main attack was to be on the weakest sector of the Allies' front, the 47 miles between Arras and La Fère (on the Oise). Two German armies, the 17th and the 2nd, were to break through the front between Arras and Saint-Quentin, north of the Somme, and then wheel right so as to force most of the British back toward the Channel, while the 18th Army, between the Somme and the Oise, protected the left flank of the advance against counterattack from the south. Code-named "Michael," this offensive was to be supplemented by three other attacks: "St. George I" against the British on the Lys River south of Armentières; "St. George II" against the British again between Armentières and Ypres; and "Blücher" against the French in Champagne. It was finally decided to use 62 divisions in the main attack, "Michael."

Preceded by an artillery bombardment using 6,000 guns, "Michael" was launched on March 21, 1918, and was helped by an early morning fog that hid the German advance from the Allied observation posts. The attack, which is known as the Second Battle of the Somme or the Battle of Saint-Quentin, took the British altogether by surprise, but it did not develop as Ludendorff had foreseen. While the 18th Army under von Hutier achieved a complete breakthrough south of the Somme, the major attack to the north was held up, mainly by the British concentration of strength at Arras. For a whole week Ludendorff, in violation of his new tactical emphasis, vainly persisted in trying to carry out his original plan instead of exploiting the unexpected success of the 18th Army, though the latter had advanced more than 40 miles westward and had reached Montdidier by March 27. At last, however, the main effort of the Germans was converted into a drive toward Amiens, which began in force on March 30. By that time the Allies had recovered from their initial dismay, and French reserves were coming up to the British line. The German drive was halted east of Amiens and so too was a renewed attack on April 4. Ludendorff then suspended his Somme offensive. This offensive had yielded the largest territorial gains of any operation on the Western Front since the First Battle of the Marne in September 1914.

The Allies' cause at least derived one overdue benefit from the collapse of one-third of the British front: at Haig's own suggestion, Foch was on March 26 appointed to coordinate the Allies' military operations; and on April 14 he was named commander in chief of the Allied armies. Previously, Haig had resisted the idea of a generalissimo.

On April 9 the Germans began "St. George I" with an attack on the extreme northern front between Armentières and the canal of La Bassée, their aim being to advance across the Lys River toward Hazebrouck. Such was the initial success of this attack that "St. George II" was launched the next day, with the capture of Kemmel Hill (Kemmelberg), southwest of Ypres, as its first objective.

(margin: Ludendorff's western offensive)

represented 852,000 gross tons, to be compared both with the 600,000 postulated by the German strategists as their monthly target and with the 700,000 that the British in March had pessimistically foretold for June. The Germans had calculated that if the world's merchant shipping could be sunk at the monthly rate of 600,000 tons, the Allies, being unable to build new merchant ships fast enough to replace those lost, could not carry on the war for more than five months. At the same time, the Germans, who had 111 U-boats operational when the unrestricted campaign began, had embarked on an extensive building program that, when weighed against their current losses of one or two U-boats per month, promised a substantial net increase in the U-boats' numbers. During April, one in every four of the merchant ships that sailed from British ports was destined to be sunk, and by the end of May the quantity of shipping available to carry the vital foodstuffs and munitions to Great Britain had been reduced to only 6,000,000 tons.

The con-
voy system
The April total, however, proved to be a peak figure—primarily because the Allies at last adopted the convoy system for the protection of merchant ships. Previously, a ship bound for one of the Allies' ports had set sail by itself as soon as it was loaded. The sea was thus dotted with single and unprotected merchant ships, and a scouting U-boat could rely on several targets coming into its range in the course of a cruise. The convoy system remedied this by having groups of merchant ships sail within a protective ring of destroyers and other naval escorts. It was logistically possible and economically worthwhile to provide this kind of escort for a group of ships. Furthermore, the combination of convoy and escort would force the U-boat to risk the possibility of a counterattack in order to sink the merchant ships, thus giving the Allies a prospect of reducing the U-boats' numbers. Despite the manifest and seemingly overwhelming benefits of the convoy system, the idea was novel and, like any untried system, met with powerful opposition from within the military. It was only in the face of extreme necessity and under great pressure from Lloyd George that the system was tried, more or less as a last resort.

The first convoy sailed from Gibraltar to Great Britain on May 10, 1917; the first from the United States sailed later in May; ships using the South Atlantic sailed in convoy from July 22. During the later months of 1917 the use of convoys caused an abrupt fall in the sinkings by U-boats: 500,500 tons in May, 300,200 in September, and only about 200,600 in November. The convoy system was so quickly vindicated that in August it was extended to shipping outward-bound from Great Britain. The Germans themselves soon observed that the British had grasped the principles of antisubmarine warfare, and that sailing ships in convoys considerably reduced the opportunities for attack.

Apart from the convoys, the Allies improved their antisubmarine technology (hydrophones, depth charges, etc.) and extended their minefields. In 1918, moreover, Admiral Sir Roger Keyes, in command at Dover, set up a system whereby the English Channel was patrolled by surface craft with searchlights, so that U-boats passing through it had to submerge themselves to depths at which they were liable to strike the mines that had been laid for them. Subsequently, most of the U-boats renounced the Channel as a way into the Atlantic and instead took the passage north of Great Britain, thus losing precious fuel and time before reaching the heavily traveled sea lanes of the western approaches to Great Britain. In the summer of 1918, U.S. minelayers laid more than 60,000 mines (13,000 of them British) in a wide belt across 180 miles of the North Sea between Scotland and Norway, so as to obstruct the U-boats' only access from Germany to the Atlantic other than the closely guarded Channel.

The cumulative effect of all these measures was the gradual containment and ultimately the defeat of the U-boat campaign, which never again achieved the success of April 1917. While sinkings by submarines, after that month, steadily fell, the losses of U-boats showed a slow but steady rise, and more than 40 were destroyed in the first six months of 1918. At the same time the replacement of merchant vessels in the building program improved steadily, until it eventually far outstripped losses. In October 1918, for example, 511,000 tons of new Allied merchant ships were launched, while only 118,559 tons were lost.

Air warfare. At the start of the war the land and sea forces used the aircraft put at their disposal primarily for reconnaissance, and air fighting began as the exchange of shots from small arms between enemy airmen meeting one another in the course of reconnoitering. Fighter aircraft armed with machine guns, however, made their appearance in 1915. Tactical bombing and the bombing of enemy air bases were also gradually introduced at this time. Contact patrolling, with aircraft giving immediate support to infantry, was developed in 1916.

Strategic
bombing
Strategic bombing, on the other hand, was initiated early enough: British aircraft from Dunkirk bombed Cologne, Düsseldorf, and Friedrichshafen in the autumn of 1914, their main objective being the sheds of the German dirigible airships, or Zeppelins; and raids by German airplanes or seaplanes on English towns in December 1914 heralded a great Zeppelin offensive sustained with increasing intensity from January 1915 to September 1916 (London was first bombed in the night of May 31–June 1, 1915). In October 1916 the British, in turn, began a more systematic offensive, from eastern France, against industrial targets in southwestern Germany.

While the British directed much of their new bombing strength to attacks on the bases of the U-boats, the Germans used theirs largely to continue the offensive against the towns of southeastern England. On June 13, 1917, in daylight, 14 German bombers dropped 118 high explosive bombs on London and returned home safely. This lesson and that of subsequent raids by the German Gotha bombers made the British think more seriously about strategic bombing and about the need for an air force independent of the other fighting services. The Royal Air Force (RAF), the world's first separate air service, was brought into active existence by a series of measures taken between October 1917 and June 1918.

Peace moves, March 1917–September 1918. Until the end of 1916, the pursuit of peace was confined to individuals and to small groups. In the following months it began to acquire a broad popular backing. Semi-starvation in towns, mutinies in the armies, and casualty lists that seemed to have no end made more and more people question the need and the wisdom of continuing the war.

Francis Joseph, Austria's venerable old emperor, died on Nov. 21, 1916. The new emperor, Charles I, and his foreign minister, Graf Ottokar Czernin, initiated peace moves in the spring of 1917 but unfortunately did not concert their diplomatic efforts, and the channels of negotiation they opened between Austria-Hungary and the Allies had dried up by that summer.

In Germany, Matthias Erzberger, a Roman Catholic member of the Reichstag, had, on July 6, 1917, proposed that territorial annexations be renounced in order to facilitate a negotiated peace. During the ensuing debates Bethmann Hollweg resigned the office of chancellor, and the emperor William II appointed the next chancellor, Ludendorff's nominee Georg Michaelis, without consulting the Reichstag. The Reichstag, offended, proceeded to pass its *Friedensresolution*, or "peace resolution," of July 19 by 212 votes. The peace resolution was a string of innocuous phrases expressing Germany's desire for peace but without a clear renunciation of annexations or indemnities. The Allies took almost no notice of it.

Erzberger's proposal of July 6 had been intended to pave the way for Pope Benedict XV's forthcoming note to the belligerents of both camps. Dated Aug. 1, 1917, this note advocated a German withdrawal from Belgium and from France, the Allies' withdrawal from the German colonies, and the restoration not only of Serbia, Montenegro, and Romania but also of Poland to independence. France and Great Britain declined to give an express reply pending Germany's statement of its attitude about Belgium, on which Germany avoided committing itself.

An unofficial peace move was made in London: on Nov. 29, 1917, the *Daily Telegraph* published a letter from Lord Lansdowne suggesting negotiations on the basis of

the status quo antebellum. Lloyd George rejected Lansdowne's theses on December 14.

The U.S. president Woodrow Wilson made himself the chief formulator and spokesman of the war aims of the Allies and the United States. The first nine months of 1918 saw Wilson's famous series of pronouncements on his war aims: the Fourteen Points (January 8), the "Four Principles" (February 11), the "Four Ends" (July 4), and the "Five Particulars" (September 27). Most important, not least because of Germany's deluded reliance on them in its eventual suing for peace, were the Fourteen Points: (1) open covenants of peace and the renunciation of secret diplomacy, (2) freedom of navigation on the high seas in wartime as well as peace, (3) the maximum possible freedom of trade, (4) a guaranteed reduction of armaments, (5) an impartial colonial settlement accommodating not only the colonialist powers but also the peoples of the colonies, (6) the evacuation of all Russian territory and respect for Russia's right of self-determination, (7) the complete restoration of Belgium, (8) a complete German withdrawal from France and satisfaction for France about Alsace-Lorraine, (9) a readjustment of Italy's frontiers on an ethnic basis, (10) an open prospect of autonomy for the peoples of Austria-Hungary, (11) the restoration of Romania, Serbia, and Montenegro, with free access to the sea for Serbia and international guarantees of the Balkan states' independence and integrity, (12) the prospect of autonomy for non-Turkish peoples of the Ottoman Empire and the unrestricted opening of the Straits, but secure sovereignty for the Turks in their own areas, (13) an independent Poland with access to the sea and under international guarantee, and (14) "a general association of nations," to guarantee the independence and integrity of all states, great and small. The three subsequent groups of pronouncements mainly consisted of idealistic expansions of themes implicit in the Fourteen Points, with increasing emphasis on the wishes of subject populations; but the first of the "Four Ends" was that every arbitrary power capable by itself of disturbing world peace should be rendered innocuous.

Wilson's peace campaign was a significant factor in the collapse of the will to fight of the German people and the decision of the German government to sue for peace in October 1918. Indeed, the Germans conducted their preliminary peace talks exclusively with Wilson. And the Armistice, when it came on Nov. 11, 1918, was formally based upon the Fourteen Points and additional Wilsonian pronouncements, with two reservations by the British and French relating to freedom of the seas and reparations.

The last offensives and the Allies' victory

THE WESTERN FRONT, MARCH–SEPTEMBER 1918

As the German strength on the Western Front was being steadily increased by the transfer of divisions from the Eastern Front (where they were no longer needed since Russia had withdrawn from the war), the Allies' main problem was how to withstand an imminent German offensive pending the arrival of massive reinforcements from the United States. Eventually Pétain persuaded the reluctant Haig that the British with 60 divisions should extend their sector of the front from 100 to 125 miles as compared with the 325 miles to be held by the French with approximately 100 divisions. Haig thus devoted 46 of his divisions to the front from the Channel to Gouzeaucourt (southwest of German-held Cambrai) and 14 to the remaining third of the front from Gouzeaucourt past German-held Saint-Quentin to the Oise River.

On the German side, between Nov. 1, 1917, and March 21, 1918, the German divisions on the Western Front were increased from 146 to 192, the troops being drawn from Russia, Galicia, and Italy. By these means the German armies in the west were reinforced by a total of about 570,000 men. Ludendorff's interest was to strike from his temporary position of strength—before the arrival of the major U.S. contingents—and at the same time to ensure that his German offensive should not fail for the same reasons as the Allies' offensives of the past three years. Accordingly he formed an offensive strategy based

on taking the tactical line of least resistance. The main German attacks would begin with brief but extremely intense artillery bombardments using a high proportion of poison gas and smoke shells. These would incapacitate the Allies' forward trenches and machine-gun emplacements and would obscure their observation posts. Then a second and lighter artillery barrage would begin to creep forward over the Allied trenches at a walking pace (in order to keep the enemy under fire), with the masses of German assault infantry advancing as closely as possible behind it. The key to the new tactics was that the assault infantry would bypass machine-gun nests and other points of strong resistance instead of waiting, as had been the previous practice on both sides, for reinforcements to mop up the obstructions before continuing the advance. The Germans would instead continue to advance in the direction of the least enemy resistance. The mobility of the German advance would thus be assured, and its deep infiltration would result in large amounts of territory being taken.

Such tactics demanded exceptionally fit and disciplined troops and a high level of training. Ludendorff accordingly drew the best troops from all the Western Front forces at his disposal and formed them into elite shock divisions. The troops were systematically trained in the new tactics, and every effort was also made to conceal the actual areas at which the German main attacks would be made.

Ludendorff's main attack was to be on the weakest sector of the Allies' front, the 47 miles between Arras and La Fère (on the Oise). Two German armies, the 17th and the 2nd, were to break through the front between Arras and Saint-Quentin, north of the Somme, and then wheel right so as to force most of the British back toward the Channel, while the 18th Army, between the Somme and the Oise, protected the left flank of the advance against counterattack from the south. Code-named "Michael," this offensive was to be supplemented by three other attacks: "St. George I" against the British on the Lys River south of Armentières; "St. George II" against the British again between Armentières and Ypres; and "Blücher" against the French in Champagne. It was finally decided to use 62 divisions in the main attack, "Michael."

Preceded by an artillery bombardment using 6,000 guns, "Michael" was launched on March 21, 1918, and was helped by an early morning fog that hid the German advance from the Allied observation posts. The attack, which is known as the Second Battle of the Somme or the Battle of Saint-Quentin, took the British altogether by surprise, but it did not develop as Ludendorff had foreseen. While the 18th Army under von Hutier achieved a complete breakthrough south of the Somme, the major attack to the north was held up, mainly by the British concentration of strength at Arras. For a whole week Ludendorff, in violation of his new tactical emphasis, vainly persisted in trying to carry out his original plan instead of exploiting the unexpected success of the 18th Army, though the latter had advanced more than 40 miles westward and had reached Montdidier by March 27. At last, however, the main effort of the Germans was converted into a drive toward Amiens, which began in force on March 30. By that time the Allies had recovered from their initial dismay, and French reserves were coming up to the British line. The German drive was halted east of Amiens and so too was a renewed attack on April 4. Ludendorff then suspended his Somme offensive. This offensive had yielded the largest territorial gains of any operation on the Western Front since the First Battle of the Marne in September 1914.

The Allies' cause at least derived one overdue benefit from the collapse of one-third of the British front: at Haig's own suggestion, Foch was on March 26 appointed to coordinate the Allies' military operations; and on April 14 he was named commander in chief of the Allied armies. Previously, Haig had resisted the idea of a generalissimo.

On April 9 the Germans began "St. George I" with an attack on the extreme northern front between Armentières and the canal of La Bassée, their aim being to advance across the Lys River toward Hazebrouck. Such was the initial success of this attack that "St. George II" was launched the next day, with the capture of Kemmel Hill (Kemmelberg), southwest of Ypres, as its first objective.

Armentières fell, and Ludendorff came to think for a time that this Battle of the Lys might be turned into a major effort. The British, however, after being driven back 10 miles, halted the Germans short of Hazebrouck. French reinforcements began to come up; and, when the Germans had taken Kemmel Hill (April 25), Ludendorff decided to suspend exploitation of the advance, for fear of a counterstroke against his front's new bulge.

Thus far Ludendorff had fallen short of strategic results, but he could claim huge tactical successes—the British casualties alone amounted to more than 300,000. Ten British divisions had to be broken up temporarily, while the German strength mounted to 208 divisions, of which 80 were still in reserve. A restoration of the balance, however, was now in sight. A dozen U.S. divisions had arrived in France, and great efforts were being made to swell the stream. Furthermore, Pershing, the U.S. commander, had placed his troops at Foch's disposal for use wherever required.

Ludendorff finally launched "Blücher" on May 27, on a front extending from Coucy, north of Soissons, eastward toward Reims. The Germans, with 15 divisions, suddenly attacked the seven French and British divisions opposing them, swarmed over the ridge of the Chemin des Dames and across the Aisne River, and, by May 30, were on the Marne, between Château-Thierry and Dormans. Once again the attack's initial success went far beyond Ludendorff's expectation or intention; and, when the Germans tried to push westward against the right flank of the Allies' Compiègne salient, which was sandwiched between the Germans' Amiens and Champagne bulges, they were checked by counterattacks, which included one sustained for a fortnight from June 6 by U.S. divisions at Belleau Wood (Bois de Belleau). An attack from Noyon, against the left flank of the Compiègne salient, came too late (June 9).

Overtaken by the inordinate fruition of his own offensives, Ludendorff paused for a month's recuperation. The tactical success of his own blows had been his undoing; yielding to their influence, he had pressed each too far and too long, using up his own reserves and causing an undue interval between blows. He had driven three great wedges into the Allied lines, but none had penetrated far enough to sever a vital rail artery, and this strategic failure left the Germans with a front whose several bulges invited flanking counterstrokes. Moreover, Ludendorff had used up many of his shock troops in the attacks, and the remaining troops, though strong in numbers, were relatively lower in quality. The Germans were to end up sustaining a total of 800,000 casualties in their great 1918 offensives. Meanwhile, the Allies were now receiving U.S. troops at the rate of 300,000 men per month.

The next German offensive, which opened the Second Battle of the Marne, was launched in Champagne on July 15. It came to nothing: a German thrust from the front east of Reims toward Châlons-sur-Marne was frustrated by the "elastic defense" that Pétain had recently been prescribing but that the local commanders had failed to practice against the offensive of May 27. A drive from Dormans, on the left flank of the Germans' huge Soissons–Reims bulge, across the Marne toward Épernay simply made the Germans' situation more precarious when Foch's long-prepared counterstroke was launched on July 18. In this

The Second Battle of the Marne

great counterstroke one of Foch's armies assailed the Germans' Champagne bulge from the west, another from the southwest, one more from the south, and a fourth from the vicinity of Reims. Masses of light tanks—a weapon on which Ludendorff had placed little reliance, preferring gas instead in his plans for the year—played a vital part in forcing the Germans into a hasty retreat. By August 2 the French had pushed the Champagne front back to a line following the Vesle River from Reims and then along the Aisne to a point west of Soissons.

Having recovered the initiative, the Allies were determined not to lose it, and for their next blow they chose again the front north and south of the Somme. The British 4th Army, including Australian and Canadian forces, with 450 tanks, struck the Germans with maximum surprise on Aug. 8, 1918. Overwhelming the German forward di-

German offensives on the Western Front, March–July 1918.

visions, who had failed to entrench themselves adequately since their recent occupation of the "Michael" bulge, the 4th Army advanced steadily for four days, taking 21,000 prisoners and inflicting as many or more casualties at the cost of only about 20,000 casualties to itself, and halting only when it reached the desolation of the old battlefields of 1916. Several German divisions simply collapsed in the face of the offensive, their troops either fleeing or surrendering. The Battle of Amiens was thus a striking material and moral success for the Allies. Ludendorff put it differently: "August 8 was the black day of the German Army in the history of the war . . . It put the decline of our fighting power beyond all doubt . . . The war must be ended." He convinced Emperor William II and Germany's political chiefs that peace negotiations should be opened before the situation became worse, as it must. The conclusions reached at a German Crown Council held at Spa were that "We can no longer hope to break the war-will of our enemies by military operations," and "the objects of our strategy must be to paralyse the enemy's war-will gradually by a strategic defensive." In other words, the German high command had abandoned hope of victory or even of holding their gains and hoped only to avoid surrender.

Meanwhile, the French had retaken Montdidier and were thrusting toward Lassigny (between Roye and Noyon); and on August 17 they began a new drive from the Compiègne salient south of Noyon. Then, in the fourth week of August, two more British armies went into action on the Arras–Albert sector of the front, the one advancing directly eastward on Bapaume, the other operating farther to the north. From then on Foch delivered a series of hammer blows along the length of the German front, launching a series of rapid attacks at different points, each broken off as soon as its initial impetus waned, and all close enough in time to attract German reserves, which consequently were unavailable to defend against the next Allied attack along a different part of the front. By the early days of September the Germans were back where they had been before March 1918—behind the Hindenburg Line.

The Allies' recovery was consummated by the first feat executed by Pershing's U.S. forces as an independent army

(hitherto the U.S. divisions in France had fought only in support of the major French or British units): the U.S. 1st Army on September 12 erased the triangular Saint-Mihiel salient that the Germans had been occupying since 1914 (between Verdun and Nancy).

The clear evidence of the Germans' decline decided Foch to seek victory in the coming autumn of 1918 instead of postponing the attempt until 1919. All the Allied armies in the west were to combine in a simultaneous offensive.

OTHER DEVELOPMENTS IN 1918

Czechs, Yugoslavs, and Poles. Something must now be said about the growth of the national movements, which, under the eventual protection of the Allies, were to result in the foundation of new states or the resurrection of long-defunct ones at the end of the war. There were three such movements: that of the Czechs, with the more backward Slovaks in tow; that of the South Slavs, or Yugoslavs (Serbs, Croats, and Slovenes); and that of the Poles. The Czech country, namely Bohemia and Moravia, belonged in 1914 to the Austrian half of the Habsburg monarchy, the Slovak to the Hungarian half. The Yugoslavs had already been represented in 1914 by two independent kingdoms, Serbia and Montenegro, but they were also predominantly numerous in territories still under Habsburg rule: Serbs in Bosnia and Hercegovina (an Austro-Hungarian condominium) and in Dalmatia (an Austrian possession); Croats in Croatia (Hungarian), in Istria (Austrian), and in Dalmatia; Slovenes in Istria and in Illyria (Austrian likewise). Poland was divided into three parts: Germany had the north and the west as provinces of the Kingdom of Prussia; Austria had Galicia (including an ethnically Ukrainian extension to the east); Russia had the rest.

The Czechs had long been restless under the Austrian regime, and one of their leading intellectual spokesmen, Tomáš Masaryk (in fact a Slovak), had already envisaged the carving of Czechoslovak and Yugoslav states out of Austria-Hungary in December 1914. In 1916 he and a fellow émigré, Edvard Beneš, based respectively in London and in Paris, organized a Czechoslovak National Council. The western Allies committed themselves to the Czechoslovak idea from 1917 onward, when Russia's imminent defection from the war made them ready to exploit any means at hand for the disabling of Austria-Hungary; and Wilson's sympathy was implicit in his successive peace pronouncements of 1918.

For the South Slavs of Austria-Hungary the Yugoslav Committee, with representatives in Paris and in London, was founded in April 1915. On July 20, 1917, this committee and the Serbian government in exile made the joint Corfu Declaration forecasting a South Slav state to comprise Serbs, Croats, and Slovenes.

The Polish nationalist leaders in the first years of the war were uncertain whether to rely on the Central Powers or on the Allies for a restoration of Poland's independence. So long as the western Allies hesitated to encourage Polish nationalism for fear of offending imperial Russia, the Central Powers seemed to be the most likely sponsors; and Austria at least allowed Józef Piłsudski, from 1914, to organize his volunteer Polish legions to serve with Austrian forces against the Russians. Austria's benevolence, however, was not reflected by Germany; and when the Two Emperors' Manifesto of Nov. 5, 1916, provided for the constitution of an independent Polish kingdom, it was clear that this kingdom would consist only of Polish territory conquered from Russia, not of any German or Austrian territory. When, after the March Revolution of 1917, the Russian provisional government had recognized Poland's right to independence, Roman Dmowski's Polish National Committee, which from 1914 had been functioning in a limited way under Russian protection, could at last count seriously on the sympathy of the western Allies. While Piłsudski declined to raise a Polish army to fight on against the new Russia, a Polish army was formed in France, as well as two army corps in Belorussia and in the Ukraine, to fight against the Central Powers. The Bolshevik Revolution and Wilson's Fourteen Points together consummated the alignment of the Poles on the side of the western powers.

Eastern Europe and the Russian periphery, March–November 1918. The Treaty of Brest-Litovsk (March 3, 1918) gave Germany a free hand to do what it liked with Russia's former possessions in eastern Europe. While they pursued their plan of 1916 for a kingdom of Poland, the Germans took new measures for the other countries. Lithuania, recognized as independent, was to be a kingdom under some German prince. Latvia and Estonia were to be merged into a grand duchy of the Baltikum under the hereditary rule of Prussia. An expeditionary force of 12,000 men, under General Graf Rüdiger von der Goltz, was sent to Finland to uphold the Finnish general C.G.E. Mannerheim's nationalist forces against the Red Guards, whom the Bolsheviks, despite their recognition of Finland's independence, were now promoting there. And finally, the Ukrainian nationalist government, which had already been challenged by a Communist one before its separate peace with the Central Powers (Brest-Litovsk, February 9), was promptly displaced by a new regime after the advance of German and Austro-Hungarian troops into its territory.

The Romanian armistice of December 1917 was converted into the Treaty of Bucharest on May 7, 1918. Under this treaty's terms, southern Dobruja was ceded to Bulgaria; northern Dobruja was put under the joint administration of the Central Powers; and the latter obtained virtual control of Romania's oil fields and communications. Romania, on the other hand, had some consolation from Bessarabia, whose nationalists, after receiving Romanian assistance against the Bolsheviks, had voted in March 1918 for their country's conditional union with Romania.

Even Transcaucasia began to slide into the German camp. The short-lived federal republic was dissolved by its three members' individual declarations of independence—Georgia's on May 26, Armenia's and Azerbaijan's on May 28. Treaties of friendship were promptly signed between Georgia and Germany and between Armenia and Turkey, and Turkish troops advanced into Azerbaijan, where they occupied Baku on September 15. The western Allies, meanwhile, were hoping that some new semblance of an Eastern Front could be conjured up if they supported the various and growing forces in Russia that were opposed to the peacemaking Bolsheviks. Since the Black Sea and the Baltic were closed to them, the Allies could land troops only on Russia's Arctic and Pacific shores. Thus, the Allied "intervention" in Russia on the side of the anti-Bolshevik ("White") forces, long to be execrated by Soviet historians, began with an Anglo-French landing at Murmansk, in the far north, on March 9, 1918. The subsequent reinforcement of Murmansk made possible the occupation of the Murmansk railway as far south as Soroka (now Belomorsk); and a further landing at Arkhangelsk in the summer raised the total Allied strength in northern Russia to some 48,000 (including 20,000 Russian "Whites"). By this time, moreover, there were some 85,000 interventionist troops in Siberia, where a strong Japanese landing at Vladivostok in April had been followed by British, French, Italian, and U.S. contingents. A "White" provisional government of Russia was set up at Omsk, with Admiral A.V. Kolchak as its dominant personality. The "White" resistance in the south of European Russia, which had been growing since November 1917, was put under the supreme command of General A.I. Denikin in April 1918.

The Balkan front, 1918. At Salonika the Allies' politically ambitious but militarily ineffective commander in chief, General Sarrail, was replaced at the end of 1917 by General Guillaumat, who was in turn succeeded in July 1918 by General L.-F.-F. Franchet d'Esperey, who launched a major offensive in September with six Serbian and two French divisions against a seven-mile front held by only one Bulgarian division.

The initial assault, preceded by heavy bombardment at night, began in the morning of Sept. 15, 1918, and a five-mile penetration was achieved by nightfall on September 16. The next day the Serbs advanced 20 miles forward, while French and Greek forces on their flanks widened the breach to 25 miles. A British attack, launched on September 18 on the front between the Vardar and Lake Doiran, prevented the Bulgars from transferring troops

The exiles and the Allies [margin note]

Allied "intervention" in Russia [margin note]

westward against the right flank of the penetration; and by September 19 the Serbian cavalry had reached Kavadarci, at the apex of the Crna–Vardar triangle. Two days later the whole Bulgarian front west of the Vardar had collapsed.

While Italian forces in the extreme west advanced on Prilep, the elated Serbs, with the French beside them, pressed on up the Vardar Valley. The British in the east now made such headway as to take Strumica, across the old Bulgarian frontier, on September 26. The Bulgars then sued for an armistice; and on September 29, when a bold French cavalry thrust up the Vardar from Veles (Titov Veles) took Skopje, key to the whole system of communications for the Balkan front, Bulgarian delegates signed the Armistice of Salonika, accepting the Allies' terms unreservedly.

The Turkish fronts, 1918. The British–Turkish front in Palestine in the summer of 1918 ran from the Jordan River westward north of Jericho and Lydda to the Mediterranean just north of Jaffa. North of this front there were three Turkish "armies" (in fact, barely stronger than divisions): one to the east of the Jordan, two to the west. These armies depended for their supplies on the Hejaz Railway, the main line of which ran from Damascus southward, east of the Jordan, and which was joined at Déraa (Dar'ā) by a branch line serving Palestine.

Liman von Sanders, Falkenhayn's successor as commander of the Turkish forces in Syria–Palestine, was convinced that the British would make their main effort east of the Jordan. Allenby, however, was really interested in taking a straight northerly direction, reckoning that the Palestine branch rail line at 'Afula and Beisān, some 60 miles behind the Turkish front, could be reached by a strategic "bound" of his cavalry and that their fall would isolate the two Turkish armies in the west.

Having by ruse and diversion induced the Turks to reduce their strength in the west, Allenby struck there on Sept. 19, 1918, with a numerical superiority of 10 to one.

The Battle of Megiddo

In this Battle of Megiddo, a British infantry attack swept the astonished defenders aside and opened the way for the cavalry, which rode 30 miles north up the coastal corridor before swinging inland to cut the Turks' northward lines of retreat. 'Afula, Beisān, and even Nazareth, farther north, were in British hands the next day.

When the Turks east of the Jordan River began to retreat on September 22, the Arabs had already severed the railway line and were lying in wait for them; and a British cavalry division from Beisān was also about to push eastward to intercept their withdrawal. Simultaneously, two more British divisions and another force of Arabs were racing on toward Damascus, which fell on October 1. The campaign ended with the capture of Aleppo and the junction of the Baghdad Railway. In 38 days Allenby's forces had advanced 350 miles and taken 75,000 prisoners at a cost of less than 5,000 casualties.

In Mesopotamia, meanwhile, the British had taken Kifrī, north of the Diyālā left-bank tributary of the Tigris, in January 1918, and Khān al-Baghdādī, up the Euphrates, in March. Pressing northward from Kifrī, they took Kirkūk in May but soon evacuated it.

The Turkish armistice

The British centre in Mesopotamia, advancing up the Tigris in October, was about to capture Mosul when the hostilities were suspended. The Ottoman government, seeing eastern Turkey defenseless and fearing an Allied advance against Istanbul from the west now that Bulgaria had collapsed, decided to capitulate. On October 30 the Armistice of Mudros was signed, on a British cruiser off Lemnos. The Turks, by its terms, were to open the Straits to the Allies; demobilize their forces; allow the Allies to occupy any strategic point that they might require and to use all Turkey's ports and railways; and order the surrender of their remaining garrisons in Arabia, Syria, and Mesopotamia. The centuries-old Ottoman Empire had come to an end.

Vittorio Veneto. After the stabilization of the Italian front on the Piave River at the end of 1917, the Austrians made no further move until the following June. They then tried not only to force the Tonale Pass and enter northeastern Lombardy but also to make two converging thrusts into central Venetia, the one southeastward from

the Trentino, the other southwestward across the lower Piave. The whole offensive came to worse than nothing, the attackers losing 100,000 men.

Diaz, the Italian commander in chief, was meanwhile deliberately abstaining from positive action until Italy should be ready to strike with success assured. In the offensive he planned, three of the five armies lining the front from the Monte Grappa sector to the Adriatic end of the Piave were to drive across the river toward Vittorio Veneto, so as to cut communications between the two Austrian armies opposing them.

When Germany, in October 1918, was at last asking for an armistice (see below), Italy's time had obviously come. On October 24, the anniversary of Caporetto, the offensive opened. An attack in the Monte Grappa sector was repulsed with heavy loss, though it served to attract the Austrian reserves, and the flooding of the Piave prevented two of the three central armies from advancing simultaneously with the third; but the latter, comprising one Italian and one British corps, having under cover of darkness and fog occupied Papadopoli Island farther downstream, won a foothold on the left bank of the river on October 27. The Italian reserves were then brought up to exploit this bridgehead.

Austrian mutiny

Mutiny was already breaking out in the Austrian forces, and on October 28 the Austrian high command ordered a general retreat. Vittorio Veneto was occupied the next day by the Italians, who were also pushing on already toward the Tagliamento. On November 3 the Austrians obtained an armistice (see below).

The collapse of Austria-Hungary. The duality of the Habsburg monarchy had been underlined from the very beginning of the war. Whereas the Austrian parliament, or Reichsrat, had been suspended in March 1914 and was not reconvened for three years, the Hungarian parliament in Budapest continued its sessions, and the Hungarian government proved itself constantly less amenable to dictation from the military than had the Austrian. The Slav minorities, however, showed little sign of anti-Habsburg feeling before Russia's March Revolution of 1917. In May 1917, however, the Reichsrat was reconvened, and just before the opening session the Czech intelligentsia sent a manifesto to its deputies calling for "a democratic Europe . . . of autonomous states." The Bolshevik Revolution of November 1917 and the Wilsonian peace pronouncements from January 1918 onward encouraged socialism, on the one hand, and nationalism, on the other, or alternatively a combination of both tendencies, among all peoples of the Habsburg monarchy.

Early in September 1918 the Austro-Hungarian government proposed in a circular note to the other powers that a conference be held on neutral territory for a general peace. This proposal was quashed by the United States on the ground that the U.S. position had already been enunciated by the Wilsonian pronouncements (the Fourteen Points, etc.). But when Austria-Hungary, after the collapse of Bulgaria, appealed on October 4 for an armistice based on those very pronouncements, the answer on October 18 was that the U.S. government was now committed to the Czechoslovaks and to the Yugoslavs, who might not be satisfied with the "autonomy" postulated heretofore. The emperor Charles had, in fact, granted autonomy to the peoples of the Austrian Empire (as distinct from the Hungarian Kingdom) on October 16, but this concession was ignored internationally and served only to facilitate the process of disruption within the monarchy: Czechoslovaks in Prague and South Slavs in Zagreb had already set up organs ready to take power.

The last scenes of Austria-Hungary's dissolution were performed very rapidly. On October 24 (when the Italians launched their very timely offensive), a Hungarian National Council prescribing peace and severance from Austria was set up in Budapest. On October 27 a note accepting the U.S. note of October 18 was sent from Vienna to Washington—to remain unacknowledged. On October 28 the Czechoslovak committee in Prague passed a "law" for an independent state, while a similar Polish committee was formed in Kraków for the incorporation of Galicia and Austrian Silesia into a unified Poland. On

The national states proclaimed independent

October 29, while the Austrian high command was asking the Italians for an armistice, the Croats in Zagreb declared Slavonia, Croatia, and Dalmatia to be independent, pending the formation of a national state of Slovenes, Croats, and Serbs. On October 30 the German members of the Reichsrat in Vienna proclaimed an independent state of German Austria.

The solicited armistice between the Allies and Austria-Hungary was signed in the Villa Giusti, near Padua, on Nov. 3, 1918, to become effective on November 4. Under its provisions, Austria-Hungary's forces were required to evacuate not only all territory occupied since August 1914 but also South Tirol, Tarvisio, the Isonzo Valley, Gorizia, Trieste, Istria, western Carniola, and Dalmatia. All German forces should be expelled from Austria-Hungary within 15 days or interned, and the Allies were to have free use of Austria-Hungary's internal communications and to take possession of most of its warships.

Count Mihály Károlyi, chairman of the Budapest National Council, had been appointed prime minister of Hungary by his king, the Austrian emperor Charles, on October 31 but had promptly started to dissociate his country from Austria—partly in the vain hope of obtaining a separate Hungarian armistice. Charles, the last Habsburg to rule in Austria-Hungary, renounced the right to participate in Austrian affairs of government on November 11, in Hungarian affairs on November 13.

THE FINAL OFFENSIVE ON THE WESTERN FRONT

It was eventually agreed among the Allied commanders that Pershing's American troops should advance across the difficult terrain of the Argonne Forest, so that the combined Allied offensive would consist of converging attacks against the whole German position west of a line drawn from Ypres to Verdun. Thus, the Americans from the front northwest of Verdun and the French from eastern Champagne, the former on the west bank of the Meuse, the latter west of the Argonne Forest, were to launch attacks on September 26, with Mézières as their objective, in order to threaten not only the Germans' supply line along the Mézières–Sedan–Montmédy railway and the natural line of retreat across Lorraine but also the hinge of the Antwerp–Meuse defensive line that the Germans were

now preparing. The British were to attack the Hindenburg Line between Cambrai and Saint-Quentin on September 27 and to try to reach the key rail junction of Maubeuge, so as to threaten the Germans' line of retreat through the Liège gap. The Belgians, with Allied support, were to begin a drive from Ypres toward Ghent on September 28.

The Americans took Vauquois and Montfaucon in the first two days of their offensive but were soon slowed down, and on October 14, when their attack was suspended, they had only reached Grandpré, less than halfway to Mézières. The French advance meanwhile was halted on the Aisne. The British, though they had broken through the German defenses by October 5 and thenceforward had open country in front of them, could not pursue the Germans fast enough to endanger their withdrawal. Nevertheless, the piercing of the Hindenburg Line unnerved the German supreme command. The Belgians were in possession of all the heights around Ypres by September 30.

The end of the German War. Georg von Hertling, who had taken the place of Michaelis as Germany's chancellor in November 1917 but had proved no more capable than he of restraining Ludendorff and Hindenburg, tendered his resignation on Sept. 29, 1918, the day of the Bulgarian armistice and of the major development of the British attack on the Western Front. Pending the appointment of a new chancellor, Ludendorff and Hindenburg obtained the Emperor's consent to an immediate peace move. On October 1 they even disclosed their despondency to a meeting of the leaders of all the national political parties, thus undermining the German home front by a sudden revelation of facts long hidden from the public and its civilian leaders. This new and bleak honesty about Germany's deteriorating military situation gave an immense impetus to the native German forces of pacifism and internal discord. On October 3 the new chancellor was appointed: he was Prince Maximilian of Baden, internationally known for his moderation and honorability. Though Max demanded a few days' interval lest Germany's overture for peace should appear too obviously an admission of imminent collapse, the military leaders insisted on an immediate move. A German note to Wilson, requesting an armistice and negotiations on the basis of Wilson's own pronouncements, was sent off in the night of October 3–4.

Prince
Max as
chancellor

Allied offensives, July–November 1918.

The U.S. answer of October 8 required Germany's preliminary assent (1) to negotiations on the sole question of the means of putting Wilson's principles into practice and (2) to the withdrawal of German forces from Allied soil. The German government's note of October 12 accepted these requirements and suggested a mixed commission to arrange the postulated evacuation. On October 14, however, the U.S. government sent a second note, which coupled allusions to Germany's "illegal and inhuman" methods of warfare with demands that the conditions of the armistice and of the evacuation be determined unilaterally by its own and the Allies' military advisers and that the "arbitrary power" of the German regime be removed in order that the forthcoming negotiations could be conducted with a government representative of the German people.

By this time the German supreme command had become more cheerful, even optimistic, as it saw that the piercing of the Hindenburg Line had not been followed by an actual Allied breakthrough. More encouragement came from reports of a slackening in the force of the Allies' attacks, largely because they had advanced too far ahead of their supply lines. Ludendorff still wanted an armistice, but only to give his troops a rest as a prelude to further resistance and to ensure a secure withdrawal to a shortened defensive line on the frontier. By October 17 he even felt that his troops could do without a rest. It was less that the situation had changed than that his impression of it had been revised; it had never been quite so bad as he had pictured it on September 29. But his dismal first impression had now spread throughout German political circles and the public. Though they had endured increasing privations and were half-starved due to the Allied blockade by mid-1918, the German people had retained their morale surprisingly well as long as they believed Germany had a prospect of achieving victory on the Western Front. When this hope collapsed in October 1918, many, and perhaps even most, Germans wished only that the war would end, though it might mean their nation would have to accept unfavourable peace terms. German public opinion, having been more suddenly disillusioned, was now far more radically defeatist than the supreme command.

A third German note to the United States, sent on October 20, agreed to the unilateral settlement of conditions for the armistice and for the evacuation, in the express belief that Wilson would allow no affront to Germany's honour. The answering U.S. note of October 23 conceded Wilson's readiness to propose an armistice to the Allies but added that the terms must be such as to make Germany incapable of renewing hostilities. Ludendorff saw this, militarily, as a demand for unconditional surrender and would therefore have continued resistance. But the situation had passed beyond his control, and on October 26 he was made to resign by the Emperor, on Prince Max's advice. On October 27 Germany acknowledged the U.S. note.

Wilson now began to persuade the Allies to agree to an armistice and negotiations according to the U.S.–German correspondence. They agreed, with two reservations: they would not subscribe to the second of the Fourteen Points (on the freedom of the seas); and they wanted "compensation . . . for damage done to the civilian population . . . and their property by the aggression of Germany." Wilson's note of November 5 apprised the Germans of these reservations and stated that Foch would communicate armistice terms to Germany's accredited representatives. On November 8 a German delegation, led by Matthias Erzberger, arrived at Rethondes, in the Forest of Compiègne, where the Germans met face to face with Foch and his party and were informed of the Allies' peace terms.

The German revolution Meanwhile, revolution was shaking Germany. It began with a sailors' mutiny at Kiel on October 29 in reaction to the naval command's order for the High Seas Fleet to go out into the North Sea for a conclusive battle. Though the U-boat crews remained loyal, the mutiny of the surface-ship crews spread to other units of the fleet, developed into armed insurrection on November 3, and progressed to open revolution the next day. There were disturbances

in Hamburg and in Bremen; "councils of soldiers and workers," like the Russian soviets, were formed in inland industrial centres; and in the night of November 7–8 a "democratic and socialist Republic of Bavaria" was proclaimed. The Social Democrats of the Reichstag withdrew their support from Prince Max's government in order to be free to contend against the Communists for the leadership of the revolution. While William II, at Spa, was still wondering whether he could abdicate his imperial German title but remain king of Prussia, Prince Max, in Berlin on November 9, on his own initiative, announced William's abdication of both titles. The Hohenzollern monarchy thus came to an end, joining those of the Habsburgs and the Romanovs. Prince Max handed his powers as chancellor over to Friedrich Ebert, a Majority Social Democrat, who formed a provisional government. A member of this government, Philipp Scheidemann, hastily proclaimed a republic. On November 10 William II took refuge in the neutral Netherlands, where on November 28 he signed his own abdication of his sovereign rights.

The Armistice. The Allies' armistice terms presented in the railway carriage at Rethondes were stiff. Germany was required to evacuate not only Belgium, France, and Alsace-Lorraine but also all the rest of the left (west) bank of the Rhine, and it had to neutralize that river's right bank between The Netherlands and Switzerland. The German troops in East Africa were to surrender; the German armies in eastern Europe were to withdraw to the prewar German frontier; the treaties of Brest-Litovsk and Bucharest were to be annulled; and the Germans were to repatriate all prisoners of war and hand over to the Allies a large quantity of war materials, including 5,000 pieces of artillery, 25,000 machine guns, 1,700 aircraft, 5,000 locomotives, and 150,000 railroad cars. And meanwhile, the Allies' blockade of Germany was to continue.

Pleading the danger of Bolshevism in a nation on the verge of collapse, the German delegation obtained some mitigation of these terms: a suggestion that the blockade might be relaxed, a reduction in the quantity of armaments to be handed over, and permission for the German forces in eastern Europe to stay put for the time being. The Germans might have held out longer for further concessions if the fact of revolution on their home front had not been coupled with the imminence of a new blow from the west.

Though the Allied advance was continuing and seemed in some sectors even to be accelerating, the main German forces had managed to retreat ahead of it. The Germans' destruction of roads and railways along the routes of their evacuation made it impossible for supplies to keep pace with the advancing Allied troops; a pause in the advance would occur while Allied communications were being repaired, and that would give the Germans a breathing space in which to rally their resistance. By November 11 the Allied advance on the northern sectors of the front had come more or less to a standstill on a line running from Pont-à-Mousson through Sedan, Mézières, and Mons to Ghent. Foch, however, now had a Franco-U.S. force of 28 divisions and 600 tanks in the south ready to strike through Metz into northeastern Lorraine. Since Foch's general offensive had absorbed the Germans' reserves, this new offensive would fall on their bared left flank and held the promise of outflanking their whole new line of defense (from Antwerp to the line of the Meuse) and of intercepting any German retreat. By this time the number of U.S. divisions in France had risen to 42. In addition, the British were about to bomb Berlin on a scale hitherto unattempted in air warfare.

Whether the Allies' projected final offensive, intended for November 14, would have achieved a breakthrough can never be known. At 5:00 AM on Nov. 11, 1918, the Armistice document was signed in Foch's railway carriage at Rethondes. At 11:00 AM on the same day, World War I came to an end.

The fact that Matthias Erzberger, who was a civilian politician rather than a soldier, headed the German armistice delegation became an integral part of the legend of the "stab in the back" (*Dolchstoss im Rücken*). This legend's theme was that the German Army was "undefeated

Table 4: Armed Forces Mobilized and Casualties in World War I*

*As reported by the U.S. War Department in February 1924. U.S. casualties as amended by the Statistical Services Center, Office of the Secretary of Defense, Nov. 7, 1957.

in the field" (*unbesiegt im Felde*) and had been "stabbed in the back"—*i.e.,* had been denied support at the crucial moment by a weary and defeatist civilian population and their leaders. This theme was adopted soon after the war's end by Ludendorff himself and by other German generals who were unwilling to admit the hopelessness of Germany's military situation in November 1918 and who wanted to vindicate the honour of German arms. The "stab in the back" legend soon found its way into German historiography and was picked up by German right-wing political agitators who claimed that Allied propaganda in Germany in the last stages of the war had undermined civilian morale and that traitors among the politicians had been at hand ready to do the Allies' bidding by signing the Armistice. Adolf Hitler eventually became the foremost of these political agitators, branding Erzberger and the leaders of the Social Democrats as the "November criminals" and advocating militaristic and expansionist policies by which Germany could redeem its defeat in the war, gain vengeance upon its enemies, and become the preeminent power in Europe.

KILLED, WOUNDED, AND MISSING

The casualties suffered by the participants in World War I dwarfed those of previous wars: some 8,500,000 soldiers died as a result of wounds and/or disease. The greatest number of casualties and wounds were inflicted by artillery, followed by small arms, and then by poison gas. The bayonet, which was relied on by the prewar French Army as the decisive weapon, actually produced few casualties. War was increasingly mechanized from 1914 and produced casualties even when nothing important was happening. On even a quiet day on the Western Front, many hundreds of Allied and German soldiers died. The

heaviest loss of life for a single day occurred on July 1, 1916, during the Battle of the Somme, when the British Army suffered 57,470 casualties.

Sir Winston Churchill once described the battles of the Somme and Verdun, which were typical of trench warfare in their futile and indiscriminate slaughter, as being waged between double or triple walls of cannons fed by mountains of shells. In an open space surrounded by masses of these guns large numbers of infantry divisions collided. They fought in this dangerous position until battered into a state of uselessness. Then they were replaced by other divisions. So many men were lost in the process and shattered beyond recognition that there is a French monument at Verdun to the 150,000 unlocated dead who are assumed to be buried in the vicinity.

This kind of war made it difficult to prepare accurate casualty lists. There were revolutions in four of the warring countries in 1918, and the attention of the new governments was shifted away from the grim problem of war losses. A completely accurate table of losses may never be compiled. The best available estimates of World War I military casualties are assembled in Table 4.

Similar uncertainties exist about the number of civilian deaths attributable to the war. There were no agencies established to keep records of these fatalities, but it is clear that the displacement of peoples through the movement of the war in Europe and in Asia Minor, accompanied as it was in 1918 by the most destructive outbreak of influenza in history, led to the deaths of large numbers. It has been estimated that the number of civilian deaths attributable to the war was higher than the military casualties, or around 13,000,000. These civilian deaths were largely caused by starvation, exposure, disease, military encounters, and massacres.

WORLD WAR II

Axis initiative and Allied reaction

The outbreak of war. By the early part of 1939 the German dictator Adolf Hitler had become determined to invade and occupy Poland. Poland, for its part, had guarantees of French and British military support should it be attacked by Germany. Hitler intended to invade Poland anyway, but first he had to neutralize the possibility that the Soviet Union would resist the invasion of its western neighbour. Secret negotiations led on August 23–24 to the signing of the German–Soviet Nonaggression Pact in Moscow. In a secret protocol of this pact, the Germans

and the Soviets agreed that Poland should be divided between them, with the western third of the country going to Germany and the eastern two-thirds being taken over by the U.S.S.R.

Having achieved this cynical agreement, the other provisions of which stupefied Europe even without divulgence of the secret protocol, Hitler thought that Germany could attack Poland with no danger of Soviet or British intervention and gave orders for the invasion to start on August 26. News of the signing, on August 25, of a formal treaty of mutual assistance between Great Britain and Poland (to supersede a previous though temporary agreement)

caused him to postpone the start of hostilities for a few days. He was still determined, however, to ignore the diplomatic efforts of the western powers to restrain him. Finally, at 12:40 PM on Aug. 31, 1939, Hitler ordered hostilities against Poland to start at 4:45 the next morning. The invasion began as ordered. In response, Great Britain and France declared war on Germany on September 3, at 11:00 AM and at 5:00 PM, respectively. World War II had begun.

Forces and resources of the European combatants, 1939. In September 1939 the Allies, namely Great Britain, France, and Poland, were together superior in industrial resources, population, and military manpower, but the German Army, or Wehrmacht, because of its armament, training, doctrine, discipline, and fighting spirit, was the most efficient and effective fighting force for its size in the world. The index of military strength in September 1939 was the number of divisions that each nation could mobilize. Against Germany's 100 infantry divisions and six armoured divisions, France had 90 infantry divisions in metropolitan France, Great Britain had 10 infantry divisions, and Poland had 30 infantry divisions, 12 cavalry brigades, and one armoured brigade (Poland had also 30 reserve infantry divisions, but these could not be mobilized quickly). A division contained from 12,000 to 25,000 men.

It was the qualitative superiority of the German infantry divisions and the number of their armoured divisions that made the difference in 1939. The firepower of a German infantry division far exceeded that of a French, British, or Polish division; the standard German division included 442 machine guns, 135 mortars, 72 antitank guns, and 24 howitzers. Allied divisions had a firepower only slightly greater than that of World War I. Germany had six armoured divisions in September 1939; the Allies, though they had a large number of tanks, had no armoured divisions at that time.

The six armoured, or panzer, divisions of the Wehrmacht comprised some 2,400 tanks. And though Germany would subsequently expand its tank forces during the first years of the war, it was not the number of tanks that Germany had (the Allies had almost as many in September 1939) but the fact of their being organized into divisions and operated as such that was to prove decisive. In accordance with the doctrines of General Heinz Guderian, the German tanks were used in massed formations in conjunction with motorized artillery to punch holes in the enemy line and to isolate segments of the enemy, which were then surrounded and captured by motorized German infantry divisions while the tanks ranged forward to repeat the process: deep drives into enemy territory by panzer divisions were thus followed by mechanized infantry and foot soldiers. These tactics were supported by dive bombers that attacked and disrupted the enemy's supply and communications lines and spread panic and confusion in its rear, thus further paralyzing its defensive capabilities. Mechanization was the key to the German blitzkrieg, or "lightning war," so named because of the unprecedented speed and mobility that were its salient characteristics. Tested and well-trained in maneuvers, the German panzer divisions constituted a force with no equal in Europe.

The German Air Force, or Luftwaffe, was also the best force of its kind in 1939. It was a ground-cooperation force designed to support the Army, but its planes were superior to nearly all Allied types. In the rearmament period from 1935 to 1939 the production of German combat aircraft steadily mounted. Table 5 shows the production of German aircraft by years.

Table 5: German Aircraft Production by Years

year	combat types	other types
1933	0	368
1934	840	1,128
1935	1,823	1,360
1936	2,530	2,582
1937	2,651	2,955
1938	3,350	1,885
1939	4,733	3,562

The standardization of engines and airframes gave the Luftwaffe an advantage over its opponents. Germany had an operational force of 1,000 fighters and 1,050 bombers in September 1939. The Allies actually had more planes in 1939 than Germany did, but their strength was made up of many different types, some of them obsolescent. Table 6 shows the number of first-line military aircraft available to the Allies at the outbreak of war.

Table 6: Allied Air Strength, September 1939

aircraft	British	French	Polish
Bombers	536	463	200
Fighters	608	634	300
Reconnaissance	96	444	—
Coastal command	216	—	—
Fleet air arm	204	194	—

Great Britain, which was held back by delays in the rearmament program, was producing one modern fighter in 1939, the Hurricane. A higher-performance fighter, the Spitfire, was just coming into production and did not enter the air war in numbers until 1940.

The value of the French Air Force in 1939 was reduced by the number of obsolescent planes in its order of battle: 131 of the 634 fighters and nearly all of the 463 bombers. France was desperately trying to buy high-performance aircraft in the United States in 1939.

At sea the odds against Germany were much greater in September 1939 than in August 1914, since the Allies in 1939 had many more large surface warships than Germany had. At sea, however, there was to be no clash between the Allied and the German massed fleets but only the individual operation of German pocket battleships and commerce raiders.

Technology of war, 1918–39. When World War I ended, the experience of it seemed to vindicate the power of the defensive over the offensive. It was widely believed that a superiority in numbers of at least three to one was required for a successful offensive. Defensive concepts underlay the construction of the Maginot Line between France and Germany and of its lesser counterpart, the Siegfried Line, in the interwar years. Yet by 1918 both of the requirements for the supremacy of the offensive were at hand: tanks and planes. The battles of Cambrai (1917) and Amiens (1918) had proved that when tanks were used in masses, with surprise, and on firm and open terrain, it was possible to break through any trench system.

The Germans learned this crucial, though subtle, lesson from World War I. The Allies on the other hand felt that their victory confirmed their methods, weapons, and leadership, and in the interwar period the French and British armies were slow to introduce new weapons, methods, and doctrines. Consequently, in 1939 the British Army did not have a single armoured division, and the French tanks were distributed in small packets throughout the infantry divisions. The Germans, by contrast, began to develop large tank formations on an effective basis after their rearmament program began in 1935.

In the air the technology of war had also changed radically between 1918 and 1939. Military aircraft had increased in size, speed, and range, and for operations at sea, aircraft carriers were developed that were capable of accompanying the fastest surface ships. Among the new types of planes developed was the dive bomber, a plane designed for accurate low-altitude bombing of enemy strong points as part of the tank-plane-infantry combination. Fast low-wing monoplane fighters were developed in all countries; these aircraft were essentially flying platforms for eight to 12 machine guns installed in the wings. Light and medium bombers were also developed that could be used for the strategic bombardment of cities and military strongpoints. The threat of bomber attacks on both military and civilian targets led directly to the development of radar in England. Radar made it possible to determine the location, the distance, and the height and speed of a distant aircraft no matter what the weather was. By December 1938 there were five radar stations established on the coast of England, and 15 additional stations were begun. So, when

war came in September 1939, Great Britain had a warning chain of radar stations that could tell when hostile planes were approaching.

The campaign in Poland, 1939. The German conquest of Poland in September 1939 was the first demonstration in war of the new theory of high-speed armoured warfare that had been adopted by the Germans when their rearmament began. Poland was a country all too well suited for such a demonstration. Its frontiers were immensely long—about 3,500 miles in all; and the stretch of 1,250 miles adjoining German territory had recently been extended to 1,750 miles in all by the German occupation of Bohemia-Moravia and of Slovakia, so that Poland's southern flank became exposed to invasion—as the northern flank, facing East Prussia, already was. Western Poland had become a huge salient that lay between Germany's jaws.

It would have been wiser for the Polish Army to assemble farther back, behind the natural defense line formed by the Vistula and San rivers, but that would have entailed the abandonment of some of the most valuable western parts of the country, including the Silesian coalfields and most of the main industrial zone, which lay west of the river barrier. The economic argument for delaying the German approach to the main industrial zone was heavily reinforced by Polish national pride and military overconfidence.

When war broke out the Polish Army was able to mobilize about 1,000,000 men, a fairly large number. The Polish Army was woefully outmoded, however, and was almost completely lacking in tanks, armoured personnel carriers, and antitank and antiaircraft guns. Yet many of the Polish military leaders clung to the double belief that their preponderance of horsed cavalry was an important asset and that they could take the offensive against the German mechanized forces. They also tended to discount the effect of Germany's vastly superior air force, which was nearly 10 times as powerful as their own.

The unrealism of such an attitude was repeated in the Polish Army's dispositions. Approximately one-third of Poland's forces were concentrated in or near the Polish Corridor (in northeastern Poland), where they were perilously exposed to a double envelopment—from East Prussia and the west combined. In the south, facing the main avenues of a German advance, the Polish forces were thinly spread. At the same time, nearly another one-third of Poland's forces were massed in reserve in the north-central part of the country, between Łódź and Warsaw, under the commander in chief, Marshal Edward Rydz-Śmigły. The Poles' forward concentration in general forfeited their chance of fighting a series of delaying actions, since their foot-marching army was unable to retreat to their defensive positions in the rear or to man them before being overrun by the invader's mechanized columns.

The 40-odd infantry divisions employed by the Germans in the invasion counted for much less than their 14 mechanized or partially mechanized divisions: these consisted of six armoured divisions; four light divisions, consisting of motorized infantry (infantry wholly transported by trucks and personnel carriers) with two armoured units; and four motorized divisions. The Germans attacked with about 1,500,000 troops in all. It was the deep and rapid thrusts of these mechanized forces that decided the issue, in conjunction with the overhead pressure of the Luftwaffe, which wrecked the Polish railway system and destroyed most of the Polish Air Force before it could come into action. The Luftwaffe's terror-bombing of Polish cities, bridges, roads, rail lines, and power stations completed the disorganization of the Polish defenses.

On Sept. 1, 1939, the German attack began. Against northern Poland, General Fedor von Bock commanded an army group comprising General Georg von Küchler's 3rd Army, which struck southward from East Prussia, and General Günther von Kluge's 4th Army, which struck eastward across the base of the Corridor. Much stronger in troops and in tanks, however, was the army group in the south under General Gerd von Rundstedt, attacking from Silesia and from the Moravian and Slovakian border: General Johannes Blaskowitz's 8th Army, on the left, was to drive eastward against Łódź; General Wilhelm List's 14th Army, on the right, was to push on toward Kraków and to turn the Poles' Carpathian flank; and General Walter von Reichenau's 10th Army, in the centre, with the bulk of the group's armour, was to deliver the decisive blow with a northwestward thrust into the heart of Poland. By September 3, when Kluge in the north had reached the Vistula and Küchler was approaching the Narew River, Reichenau's armour was already beyond the Warta; two days later his left wing was well to the rear of Łódź and his right wing at Kielce; and by September 8 one of his armoured corps was in the outskirts of Warsaw, having advanced 140 miles in the first week of war. Light divisions on Reichenau's right were on the Vistula between Warsaw and Sandomierz by September 9, while List, in the south, was on the San above and below Przemyśl. At the same time, the 3rd Army tanks, led by Guderian, were across the Narew attacking the line of the Bug River, behind Warsaw. All the German armies had made progress in fulfilling their parts in the great enveloping maneuver planned by General Franz Halder, chief of the general staff, and directed by General Walther von Brauchitsch, the commander in chief. The Polish armies were splitting up into uncoordinated fragments, some of which were retreating while others were delivering disjointed attacks on the nearest German columns.

On September 10 the Polish commander in chief, Marshal Edward Rydz-Śmigły, ordered a general retreat to the southeast. The Germans, however, were by that time not only tightening their net around the Polish forces west of the Vistula (in the Łódź area and, still farther west, around Poznań) but also penetrating deeply into eastern Poland. The Polish defense was already reduced to random efforts by isolated bodies of troops when another blow fell: on Sept. 17, 1939, Soviet forces entered Poland from the east. The next day, the Polish government and high command crossed the Romanian frontier on their way into exile. The Warsaw garrison held out against the Germans until September 28, undergoing terror-bombings and artillery barrages that reduced parts of the city to rubble, with no regard for the civilian population. The last considerable fragment of the Polish Army resisted until October 5; and some guerrilla fighting went on into the winter. The Germans took a total of 700,000 prisoners, and about 80,000 Polish soldiers escaped over neutral frontiers. Polish total casualties (killed, wounded, and missing) remain unknown, while the Germans sustained about 45,000 casualties. Poland was conquered for partition between Germany and the U.S.S.R., the forces of which met and greeted each other on Polish soil. On September 28 another secret German–Soviet protocol modified the arrangements of August: all Lithuania was to be a Soviet sphere of influence, not a German one; but the dividing line in Poland was changed in Germany's favour, being moved eastward to the Bug River.

The Baltic states and the Russo-Finnish War, 1939–40. Profiting quickly from its understanding with Germany, the U.S.S.R. on Oct. 10, 1939, constrained Estonia, Latvia, and Lithuania to admit Soviet garrisons onto their territories. Approached with similar demands, Finland refused to comply, even though the U.S.S.R. offered territorial compensation elsewhere for the cessions that it was requiring for its own strategic reasons. Finland's armed forces amounted to about 200,000 troops in 10 divisions. The Soviets eventually brought about 70 divisions (about 1,000,000 men) to bear in their attack on Finland, along with about 1,000 tanks. Soviet troops attacked Finland on Nov. 30, 1939.

The invaders succeeded in isolating the little Arctic port of Petsamo in the far north but were ignominiously repulsed on all of the fronts chosen for their advance. On the Karelian Isthmus, the massive reinforced-concrete fortifications of Finland's Mannerheim Line blocked the Soviet forces' direct land route from Leningrad into Finland. The Soviet planners had grossly underestimated the Finns' national will to resist and the natural obstacles constituted by the terrain's numerous lakes and forests.

The western powers exulted overtly over the humiliation

The Soviet invasion of eastern Poland

of the Soviet Union. One important effect of Finland's early successes was to reinforce the tendency of both Hitler and the western democracies to underestimate the Soviet military capabilities. But in the meantime, the Soviet strategists digested their hard-learned military lessons.

On Feb. 1, 1940, the Red Army launched 14 divisions into a major assault on the Mannerheim Line. The offensive's weight was concentrated along a 10-mile sector of the line near Summa, which was pounded by a tremendous artillery bombardment. As the fortifications were pulverized, tanks and sledge-carried infantry advanced to occupy the ground while the Soviet Air Force broke up attempted Finnish counterattacks. After little more than a fortnight of this methodical process, a breach was made through the whole depth of the Mannerheim Line. Once the Soviets had forced a passage on the Karelian Isthmus, Finland's eventual collapse was certain. On March 6 Finland sued for peace, and a week later the Soviet terms were accepted: the Finns had to cede the entire Karelian Isthmus, Viipuri, and their part of the Rybachy Peninsula to the Soviets. The Finns had suffered about 70,000 casualties in the campaign, the Soviets more than 200,000.

The war in the west, September 1939–June 1940. During their campaign in Poland, the Germans kept only 23 divisions in the west to guard their frontier against the French, who had nearly five times as many divisions mobilized. The French commander in chief, General Maurice-Gustave Gamelin, proposed an advance against Germany through neutral Belgium and The Netherlands, in order to have room to exercise his ponderous military machine. He was overruled, however, and French assaults on the 100-mile stretch of available front along the Franco-German frontier had barely dented the German defenses when the collapse of Poland prompted the recall of Gamelin's advanced divisions to defensive positions in the Maginot Line (see below). From October 1939 to March 1940, successive plans were developed for counteraction in the event of a German offensive through Belgium—all of them based on the assumption that the Germans would come across the plain north of Namur, not across the hilly and wooded Ardennes. The Germans would indeed have taken the route foreseen by the French if Hitler's desire for an offensive in November 1939 had not been frustrated, on the one hand, by bad weather and, on the other, by the hesitations of his generals; but in March 1940 the bold suggestion of General Erich von Manstein that an offensive through the Ardennes should, in fact, be practicable for tank forces was adopted by Hitler, despite orthodox military opinion.

Meanwhile, Hitler's immediate outlook had been changed by considerations about Scandinavia. Originally he had intended to respect Norway's neutrality. Then rumours leaked out, prematurely, of British designs on Norway—as, in fact, Winston Churchill, first lord of the Admiralty, was arguing that mines should be laid in Norwegian waters to stop the export of Swedish iron ore from Gällivare to Germany through Norway's rail terminus and port of Narvik. The British Cabinet, in response to Churchill, authorized at least the preparation of a plan for a landing at Narvik; and in mid-December 1939 a Norwegian politician, Vidkun Quisling, leader of a pro-Nazi party, was introduced to Hitler. On Jan. 27, 1940, Hitler ordered plans for an invasion of Norway, for use if he could no longer respect Norway's neutrality.

After France's failure to interrupt the German conquest of Poland, the western powers and the Germans were so inactive with regard to land operations that journalists began to speak derisively, over the next six months, of the "phony war." At sea, however, the period was somewhat more eventful. German U-boats sank the British aircraft carrier *Courageous* (September 17) and the battleship *Royal Oak* (October 14). The U-boats' main warfare, however, was against merchant shipping: they sank more than 110 vessels in the first four months of the war. Both the Germans and the British, meanwhile, were engaged in extensive mine laying.

In surface warfare at sea, the British were on the whole more fortunate than the Germans. A German pocket battleship in the Atlantic, the *Admiral Graf Spee* sank nine

ships before coming to a tragic end: having sustained and inflicted damage in an engagement with three British cruisers off the Río de la Plata on Dec. 13, 1939, she made off to Montevideo and obtained leave to spend four days there for repairs; the British mustered reinforcements for the two cruisers still capable of action after the engagement, namely the *Ajax* and the *Achilles*, and brought the *Cumberland* to the scene in time; but, on December 17, when the *Graf Spee* put to sea again, her crew scuttled her a little way out of the harbour before the fight could be resumed.

The invasion of Norway. British plans for landings on the Norwegian coast in the third week of March 1940 were temporarily postponed. Prime Minister Neville Chamberlain, however, was by that time convinced that some aggressive action ought to be taken; and Paul Reynaud, who succeeded Daladier as France's premier on March 21, was of the same opinion. (Reynaud had come into office on the surge of the French public's demand for a more aggressive military policy and quicker offensive action against Germany.) It was agreed that mines should be laid in Norwegian waters and that the mining should be followed by the landing of troops at four Norwegian ports, Narvik, Trondheim, Bergen, and Stavanger.

Because of Anglo-French arguments, the date of the mining was postponed from April 5 to April 8. The postponement was catastrophic. Hitler had on April 1 ordered the German invasion of Norway to begin on April 9; so, when on April 8 the Norwegian government was preoccupied with earnest protest about the British mine laying, the German expeditions were well on their way.

On April 9, 1940, the major Norwegian ports from Oslo northward to Narvik (1,200 miles away from Germany's naval bases) were occupied by advance detachments of German troops. At the same time, a single parachute battalion (the first ever employed in warfare) took the Oslo and Stavanger airfields, and 800 operational aircraft overawed the Norwegian population. Norwegian resistance at Narvik, at Trondheim (the strategic key to Norway), at Bergen, at Stavanger, and at Kristiansand had been overcome very quickly; and Oslo's effective resistance to the seaborne forces was nullified when German troops from the airfield entered the city.

Simultaneously, along with their Norwegian enterprise, the Germans on April 9 occupied Denmark, sending troopships, covered by aircraft, into Copenhagen harbour and marching over the land frontier into Jutland. This occupation was obviously necessary for the safety of their communications with Norway.

Allied troops began to land at Narvik on April 14. Shortly afterward, British troops were landed also at Namsos and at Åndalsnes, to attack Trondheim from the north and from the south, respectively. The Germans, however, landed fresh troops in the rear of the British at Namsos and advanced up the Gudbrandsdal from Oslo against the force at Åndalsnes. By this time the Germans had about 25,000 troops in Norway. By May 2, both Namsos and Åndalsnes were evacuated by the British. The Germans at Narvik held out against five times as many British and French troops until May 27. By that time the German offensive in France had progressed to such an extent that the British could no longer afford any commitment in Norway, and the 25,000 Allied troops were evacuated from Narvik 10 days after their victory. The Norwegian king Haakon VII and his government left Norway for Britain at the same time. Hitler garrisoned Norway with about 300,000 troops for the rest of the war. By occupying Norway, Hitler had ensured the protection of Germany's supply of iron ore from Sweden and had obtained naval and air bases with which to strike at Britain if necessary.

What was to happen in Norway became a less important question for the western powers when, on May 10, 1940, they were surprised by Hitler's long-debated stroke against them through the Low Countries.

The invasion of the Low Countries and France. France's 800,000-man standing army was thought at the time to be the most powerful in Europe. But the French had not progressed beyond the defensive mentality inherited from World War I, and they relied primarily on their

The German invasion of Norway

Maginot Line for protection against a German offensive. The Maginot Line was an extremely well-developed chain of fortifications running from the Swiss frontier opposite Basel northward along the left bank of the Rhine and then northwestward no farther than Montmédy, near the Belgian frontier south of the Ardennes Forest. The line consisted of a series of giant pillboxes and other defensive installations constructed in depth, equipped with underground supply and communications facilities, and connected by rail lines, with all its heavy guns pointed east at the German frontier. Depending heavily on the line as a defense against German attack, the French had 41 divisions manning it or backing it, whereas only 39 divisions were watching the long stretch of frontier north of it, from Montmédy through the Ardennes and across Flanders to the English Channel.

In their plan for the invasion of France and the Low Countries, the Germans kept General Wilhelm von Leeb's Army Group C facing the Maginot Line so as to deter the French from diverting forces from it, while launching Bock's Army Group B into the basin of the Lower Maas River north of Liège and Rundstedt's Army Group A

Axis and Allied movements in Europe and North Africa, 1940–42, and (inset) German invasion of the Low Countries and France, 1940.

into the Ardennes. Army Group B comprised Küchler's 18th Army, with one armoured division and airborne support, to attack The Netherlands, and Reichenau's 6th, with two armoured divisions, to advance over the Belgian plain. These two armies would have to deal not only with the Dutch and Belgian armies but also with the forces that the Allies, according to their plan, would send into the Low Countries, namely two French armies and nine British divisions. Rundstedt's Army Group A, however, was much stronger, comprising as it did Kluge's 4th Army, List's 12th, and General Ernst Busch's 16th, with General Maximilian von Weichs's 2nd in reserve, besides a large armoured group under Kleist and a smaller one under General Hermann Hoth, and amounting in all to 44 divisions, seven of them armoured, with 27 divisions in reserve. Army Group A thus amounted to more than 1,500,000 men and more than 1,500 tanks, and it would strike at the weak hinge of the Allies' wheel into Belgium—that is to say, at two French armies, General Charles Huntziger's 2nd and General André Corap's 9th, which together mustered only 12 infantry and four horsed cavalry divisions and stood, respectively, east and west of Sedan on the least-fortified stretch of the French frontier. Against this weak centre of the Allied line were thus massed nearly two-thirds of Germany's forces in the west and nearly three-quarters of its tank forces.

The Dutch Army comprised 10 divisions and the equivalent of 10 more in smaller formations, and thus totaled more than 400,000 men. It apparently had a good chance of withstanding the German invasion, since the attacking German army comprised only seven divisions, apart from the airborne forces it would use. The Dutch, however, had a wide front, a very sensitive and loosely settled rear, very few tanks, and no experience of modern warfare. On May 10, the German attack on The Netherlands began with the capture by parachutists of the bridges at Moerdijk, at Dordrecht, and at Rotterdam and with landings on the airfields around The Hague. On the same day, the weakly held Peel Line, south of the westward-turning arc of the Maas, was penetrated by the German land forces; and on May 11 the Dutch defenders fell back westward past Tilburg to Breda, with the consequence that the French 7th Army, under General Henri Giraud, whose leading forces had sped forward across Belgium over the 140 miles to Tilburg, fell back to Breda likewise. The German tanks thus had a clear road to Moerdijk, and by noon on May 12 they were in the outskirts of Rotterdam. North of the Maas, meanwhile, where the bulk of the Dutch defense was concentrated, the Germans achieved a narrow breach of the Geld Valley line on May 12, whereupon the Dutch, unable to counterattack, retreated to the "Fortress of Holland" Line protecting Utrecht and Amsterdam. Queen Wilhelmina and her government left the country for England on May 13; and the next day the Dutch commander in chief, General Henri Gerard Winkelman, surrendered to the Germans, who had threatened to bomb Rotterdam and Utrecht, as places in the front line of the fighting, if resistance continued. In fact, Rotterdam was bombed, after the capitulation, by 30 planes through a mistake in the Germans' signal communications.

The news of the German onslaught in the Low Countries, dismaying as it was to the Allies, had one effect that was to be of momentous importance to their fortunes: Chamberlain, whose halfhearted conduct of the war had been bitterly criticized in the House of Commons during the debate of May 7–8 on the campaign in Norway, resigned office in the evening of May 10 and was succeeded as prime minister by Churchill, who formed a coalition government.

For the first phase of the invasion of the Belgian plain north of Liège, Reichenau had four army corps, one armoured corps, and only 500 airborne troops; but he also had massive cooperation from the German Luftwaffe, whose dive bombers and fighters played a major role in breaking down the Belgian defenses. West of the Maastricht "appendix" of indefensible Dutch territory separating Belgium from Germany, the fortress of Eben Emael, immediately opposite Maastricht, and the line of the Albert Canal constituted the Belgians' foremost defensive position. On May 10 German airborne troops landed in gliders on the top of the fortress and on bridges over the canal. On May 11 the Belgian front was broken, the German tanks running on westward and some of the infantry turning southward to take Liège from the rear, while the Belgians made a general retreat to the Antwerp–Namur, or Dyle, Line. French and British divisions had just arrived on this Dyle Line, and General René Prioux's two tank divisions went out from it to challenge the German advance. After a big battle on May 14, however, Prioux's tanks had to retire to the consolidated Dyle Line; and on May 15, notwithstanding a successful defense against a German attack, Gamelin ordered the abandonment of the position, because events farther to the south had made it strategically untenable.

The chances for success of the German offensive against France hinged on a German advance through the hilly and dense Ardennes Forest, which the French considered to be impassable to tanks. But the Germans did succeed in moving their tank columns through that difficult belt of country by means of an amazing feat of staff work. While the armoured divisions used such roads through the forest as were available, infantry divisions started alongside them by using field and woodland paths and marched so fast across country that the leading ones reached the Meuse River only a day after the armoured divisions had.

The decisive operations in France were those of Rundstedt's Army Group A. Kleist's tanks on May 10 took only three hours to cover the 30 miles from the eastern border of independent Luxembourg to the southeastern border of Belgium; and on May 11 the French cavalry divisions that had ridden forward into the Ardennes to oppose them were thrown back over the Semois River. By the evening of May 12 the Germans were across the Franco-Belgian frontier and overlooking the Meuse River. The defenses of this sector were rudimentary, and it was the least-fortified stretch of the whole French front. Worse still, the defending French 2nd and 9th armies had hardly any antitank guns or antiaircraft artillery with which to slow down the German armoured columns and shoot down their dive bombers. Such was the folly of the French belief that a German armoured thrust through the Ardennes was unlikely.

On May 13 Kleist's forces achieved a threefold crossing of the Meuse River. At Sedan wave after wave of German dive bombers swooped on the French defenders of the south bank. The latter could not stand the nerve-racking strain, and the German troops were able to push across the river in rubber boats and on rafts. The tremendous air bombardment was the decisive factor in the crossings. A thousand aircraft supported Kleist's forces, while only a few French aircraft intervened in a gallant but hopeless effort to aid their troops on the ground. Next day, after the tanks had been brought across, Guderian widened the Sedan bridgehead and beat off French counterattacks. On May 15 he broke through the French defenses into open country, turning westward in the direction of the English Channel. On May 16 his forces swept on west for nearly 50 miles. His superiors tried to put on the brake, feeling that such rapid progress was hazardous, but the pace of the German drive upset the French far more, and their collapse spread as Reinhardt's corps joined in the pressure. When more German tanks crossed the Meuse between Givet and Namur, the breach of the French front was 60 miles wide.

Driving westward down the empty corridor between the Sambre and the Aisne rivers, Guderian's tanks crossed the Oise River on May 17 and reached Amiens two days later. Giraud, who on May 15 had superseded Corap in command of the French 9th Army, was thus frustrated in his desperate plan of checking the Germans on the Oise; and Kleist, meanwhile, by lining the Aisne progressively with tanks until the infantry came up to relieve them, was protecting the southwestern flank of the advance against the danger of a counteroffensive from the south. Indeed, when the Germans, on May 15, were reported to be crossing the Aisne River between Rethel and Laon, Gamelin told Reynaud that he had no reserves in that sector and that Paris might fall within two days' time.

The German breakthrough into France

Thereupon Reynaud, though he postponed his immediate decision to move the government to Tours, summoned General Maxime Weygand from Syria to take Gamelin's place as commander in chief; but Weygand did not arrive until May 19.

Guderian's tanks were at Abbeville on May 20, and on May 22 he turned northward to threaten Calais and Dunkirk, while Reinhardt, swinging south of the British rear at Arras, headed for the same objectives, the remaining ports by which the British Expeditionary Force (BEF) could be evacuated.

The evacuation from Dunkirk. For the Allies, all communication between their northern and southern forces was severed by the arc of the westward German advance from the Ardennes to the Somme. The Allied armies in the north, having fallen back from the Dyle Line to the Escaut (Schelde), were being encircled, and already on May 19 the British commander, Viscount Gort, was considering the withdrawal of the BEF by sea. On May 21, however, to satisfy orders from London for more positive action, he launched an attack from Arras southward against the right flank of the Germans' corridor; but, though it momentarily alarmed the German high command, this small counterstroke lacked the armoured strength necessary for success. Meanwhile, Guderian's tanks had swept up past Boulogne and Calais and were crossing the canal defense line close to Dunkirk when, on May 24, an inexplicable order from Hitler not only stopped their advance but actually called them back to the canal line just as Guderian was expecting to drive into Dunkirk.

Dunkirk was now the only port left available for the withdrawal of the mass of the BEF from Europe, and the British Cabinet at last decided to save what could be saved. The British Admiralty had been collecting every kind of small craft it could find to help in removing the troops, and the British retreat to the coast now became a race to evacuate the troops before the Germans could occupy Dunkirk. Evacuation began on May 26 and became still more urgent the next day, when the Belgians, their right wing and their centre broken by Reichenau's advance, sued for an armistice. On May 27, likewise, bombing by the Luftwaffe put the harbour of Dunkirk out of use, so that many of the thousands of men thronging the 10-mile stretch of beaches had to be ferried out to sea by petty craft pressed into service by the Royal Navy and manned largely by amateur seamen, though the harbour's damaged breakwater still offered a practicable exit for the majority. By June 4, when the operation came to an end, 198,000 British and 140,000 French and Belgian troops had been saved; but virtually all of their heavy equipment had to be abandoned, and, of the 41 destroyers participating, six were sunk and 19 others damaged. The men who were saved represented a considerable part of the experienced troops possessed by Great Britain and were an inestimable gain to the Allies. The success of the near-miraculous evacuation from Dunkirk was due, on the one hand, to fighter cover by the Royal Air Force from the English coast and on the other to Hitler's fatal order of May 24 halting Guderian. That order had been made for several reasons, chiefly: Hermann Göring, head of the Luftwaffe, had mistakenly assured Hitler that his aircraft alone could destroy the Allied troops trapped on the beaches at Dunkirk; and Hitler himself seems to have believed that Great Britain might accept peace terms more readily if its armies were not constrained into humiliating surrender. Three days passed before Brauchitsch, the German Army commander in chief, was able to persuade Hitler to withdraw his orders and allow the German armoured forces to advance on Dunkirk. But they met stronger opposition from the British, who had had time to solidify their defenses, and almost immediately Hitler stopped the German armoured forces again, ordering them instead to move south and prepare for the attack on the Somme–Aisne line.

The campaign in northern France was wound up by Küchler's forces, after both Guderian and Reichenau had been ordered southward. Altogether, the Germans had taken more than 1,000,000 prisoners in three weeks, at a cost of 60,000 casualties. Some 220,000 Allied troops, however, were rescued by British ships from France's

northwestern ports (Cherbourg, Saint-Malo, Brest, and Saint-Nazaire), thus bringing the total of Allied troops evacuated to about 558,000.

There remained the French armies south of the Germans' Somme–Aisne front. The French had lost 30 divisions in the campaign so far. Weygand still managed to muster 49 divisions, apart from the 17 left to hold the Maginot Line, but against him the Germans had 130 infantry divisions as well as their 10 divisions of tanks. The Germans, after redisposing their units, began a new offensive on June 5 from their positions on the Somme. The French resisted stiffly for two days, but on June 7 the German tanks in the westernmost sector, led by Major General Erwin Rommel, broke through toward Rouen, and on June 9 they were over the Seine. On June 9 the Germans attacked on the Aisne: the infantry forced the crossings, and then Guderian's armour drove through the breach toward Châlons-sur-Marne before turning eastward for the Swiss frontier, thus isolating all the French forces still holding the Maginot Line.

Italy's entry into the war and the French Armistice. Italy had been unprepared for war when Hitler attacked Poland, but if the Italian leader, Benito Mussolini, was to reap any positive advantages from partnership with Hitler it seemed that Italy would have to abandon its nonbelligerent stance before the western democracies had been defeated by Germany singlehanded. The obvious collapse of France convinced Mussolini that the time to implement his Pact of Steel with Hitler had come, and on June 10, 1940, Italy declared war against France and Great Britain. With about 30 divisions available on their Alpine frontier, the Italians delayed their actual attack on southeastern France until June 20, but it achieved little against the local defense. In any case, the issue in France had already been virtually settled by the victory of Italy's German ally.

Meanwhile, Reynaud had left Paris for Cangé, near Tours; and Weygand, after speaking frankly and despondently to Churchill at the Allied military headquarters at Briare on June 11, told Reynaud and the other ministers at Cangé on June 12 that the battle for France was lost and that a cessation of hostilities was compulsory. There was little doubt that he was correct in this estimate of the military situation: the French armies were now splitting up into fragments. Reynaud's government was divided between the advocates of capitulation and those who, with Reynaud, wanted to continue the war from French North Africa. The only decision that it could make was to move itself from Tours to Bordeaux.

The Germans entered Paris on June 14, 1940, and were driving still deeper southward along both the western and eastern edges of France. Two days later they were in the Rhône Valley. Meanwhile, Weygand was still pressing for an armistice, backed by all the principal commanders. Reynaud resigned office on June 16, whereupon a new government was formed by Marshal Philippe Pétain, the revered and aged hero of the Battle of Verdun in World War I. In the night of June 16 the French request for an armistice was transmitted to Hitler. While discussion of the terms went on, the German advance went on too. Finally, on June 22, 1940, at Rethondes, the scene of the signing of the Armistice of 1918, the new Franco-German Armistice was signed. The Franco-Italian Armistice was signed on June 24. Both armistices came into effect early on June 25.

The Armistice of June 22 divided France into two zones, one to be under German military occupation, one to be left to the French in full sovereignty. The occupied zone comprised all northern France from the northwestern frontier of Switzerland to the Channel and from the Belgian and German frontiers to the Atlantic, together with a strip extending from the lower Loire southward along the Atlantic coast to the western end of the Pyrenees; the unoccupied zone comprised only two-fifths of France's territory, the southeast. The French Navy and Air Force were to be neutralized, but it was not required that they be handed over to the Germans. The Italians granted very generous terms to the French: the only French territory that they claimed to occupy was the small frontier tract that their forces had succeeded in overrunning since June

20. Meanwhile, from June 18, General Charles de Gaulle, whom Reynaud had sent on a military mission to London on June 5, was broadcasting appeals for the continuance of France's war.

The collapse of France in June 1940 posed a severe naval problem to the British, because the powerful French Navy still existed: strategically, it was of immense importance to the British that these French ships not fall into German hands, since they would have tilted the balance of sea power decidedly in favour of the Axis—the Italian Navy being now also at war with Britain. Mistrustful of promises that the French ships would be used only for "supervision and minesweeping," the British decided to immobilize them. Thus, on July 3, 1940, the British seized all French ships in British-controlled ports, encountering only nominal resistance. But when British ships appeared off Mers el-Kébir, near Oran on the Algerian coast, and demanded that the ships of the important French naval force there either join the Allies or sail out to sea, the French refused to submit, and the British eventually opened fire, damaging the battleship *Dunkerque,* destroying the *Bretagne,* and disabling several other vessels. Thereupon, Pétain's government, which on July 1 had installed itself at Vichy, on July 4 severed diplomatic relations with the British. In the eight following days, the constitution of France's Third Republic was abolished and a new French state created, under the supreme authority of Pétain himself. The few French colonies that rallied to General de Gaulle's Free French movement were strategically unimportant.

The Battle of Britain. With France conquered, Hitler could now turn his forces on Germany's sole remaining enemy: Great Britain, which was protected from the formidable German Army by the waters of the English Channel. On July 16, 1940, Hitler issued a directive ordering the preparation and, if necessary, the execution of a plan for the invasion of Great Britain. But an amphibious invasion of Britain would only be possible, given Britain's large navy, if Germany could establish control of the air in the battle zone. To this end, the Luftwaffe chief, Göring, on August 2 issued the "Eagle Day" directive, laying down a plan of attack in which a few massive blows from the air were to destroy British air power and so open the way for the amphibious invasion, termed Operation "Sea Lion." Victory in the air battle for the Luftwaffe would indeed have exposed Great Britain to invasion and occupation. The victory by the Royal Air Force (RAF) Fighter Command blocked this possibility and, in fact, created the conditions for Great Britain's survival, for the extension of the war, and for the eventual defeat of Nazi Germany.

The forces engaged in the battle were relatively small. The British disposed some 600 frontline fighters to defend the country. The Germans made available about 1,300 bombers and dive bombers, and about 900 single-engined and 300 twin-engined fighters. These were based in an arc around England from Norway to the Cherbourg Peninsula in northern coastal France. The preliminaries of the Battle of Britain occupied June and July 1940, the climax August and September, and the aftermath—the so-called Blitz—the winter of 1940–41. In the campaign, the Luftwaffe had no systematic or consistent plan of action: sometimes it tried to establish a blockade by the destruction of British shipping and ports; sometimes, to destroy Britain's Fighter Command by combat and by the bombing of ground installations; and sometimes, to seek direct strategic results by attacks on London and other populous centres of industrial or political significance. The British, on the other hand, had prepared themselves for the kind of battle that in fact took place. Their radar early warning, the most advanced and the most operationally adapted system in the world, gave Fighter Command adequate notice of where and when to direct their fighter forces to repel German bombing raids. The Spitfire, moreover, though still in short supply, was unsurpassed as an interceptor by any fighter in any other air force.

The British fought not only with the advantage—unusual for them—of superior equipment and undivided aim but also against an enemy divided in object and condemned by circumstance and by lack of forethought to fight at a tactical disadvantage. The German bombers lacked the bomb-load capacity to strike permanently devastating blows and also proved, in daylight, to be easily vulnerable to the Spitfires and Hurricanes. Britain's radar, moreover, largely prevented them from exploiting the element of surprise. The German dive bombers were even more vulnerable to being shot down by British fighters, and long-range fighter cover was only partially available from German fighter aircraft, since the latter were operating at the limit of their flying range.

The German air attacks began on ports and airfields along the English Channel, where convoys were bombed and the air battle was joined. In June and July 1940, as the Germans gradually redeployed their forces, the air battle moved inland over the interior of Britain. On August 8 the intensive phase began, when the Germans launched bombing raids involving up to nearly 1,500 aircraft a day and directed them against the British fighter airfields and radar stations. In four actions, on August 8, 11, 12, and 13, the Germans lost 145 aircraft as against the British loss of 88. By late August the Germans had lost more than 600 aircraft, while the RAF only 260, but the RAF was losing badly needed fighters and experienced pilots at too great a rate, and its effectiveness was further hampered by bombing damage done to the radar stations. At the beginning of September the British retaliated by unexpectedly launching a bombing raid on Berlin, which so infuriated Hitler that he ordered the Luftwaffe to shift its attacks from Fighter Command installations to London and other cities. These assaults on London, Coventry, Liverpool, and other cities went on unabated for several months. But already, by September 15, on which day the British believed, albeit incorrectly, that they had scored their greatest success by destroying 185 German aircraft, Fighter Command had demonstrated to the Luftwaffe that it could not gain air ascendancy over Britain. This was because British fighters were simply shooting down German bombers faster than German industry could produce them. The Battle of Britain was thus won, and the invasion of England was postponed indefinitely by Hitler. The British had lost more than 900 fighters but had shot down about 1,700 German aircraft.

During the following winter, the Luftwaffe maintained a bombing offensive, carrying out night-bombing attacks on Britain's larger cities. By February 1941 the offensive had declined, but in March and April there was a revival, and nearly 10,000 sorties were flown, with heavy attacks made on London. Thereafter German strategic air operations over England withered.

Central Europe and the Balkans, 1940–41. The continued resistance of the British caused Hitler once more to change his timetable. His great design for a campaign against the U.S.S.R. had originally been scheduled to begin about 1943—by which time he should have secured the German position on the rest of the European continent by a series of "localized" campaigns and have reached some sort of compromise with Great Britain. But in July 1940, seeing Great Britain still undefeated and the United States increasingly inimical to Germany, he decided that the conquest of the European part of the Soviet Union must be undertaken in May 1941, in order both to demonstrate Germany's invincibility to Great Britain and to deter the United States from intervention in Europe (because the elimination of the U.S.S.R. would strengthen the Japanese position in the Far East and in the Pacific). Events in the interval, however, were to make him change his plan once again.

While the invasion of the U.S.S.R. was being prepared, Hitler was much concerned to extend German influence across Slovakia and Hungary into Romania, the oil fields of which he was anxious to secure against Soviet attack and the military manpower of which might be joined to the forces of the German coalition. In May 1940 he obtained an oil and arms pact from Romania; but, when Romania, after being constrained by a Soviet ultimatum in June to cede Bessarabia and northern Bukovina to the U.S.S.R., requested a German military mission and a German guarantee of its remaining frontiers, Hitler refused to comply until the claims of other states against Romania had been met. Romania was compelled to cede

German–Romanian relations

southern Dobruja to Bulgaria on August 21 (an act that was formalized in the Treaty of Craiova on September 7); but its negotiations with Hungary about Transylvania were broken off on August 23. Since, if war had broken out between Romania and Hungary, the U.S.S.R. might have intervened and won control over the oil wells, Hitler decided to arbitrate immediately: by the Vienna Award of August 30, Germany and Italy assigned northern Transylvania, including the Szekler district, to Hungary, and Germany then guaranteed what was left of Romania. In the face of the Romanian nationalists' outcry against these proceedings, the king, Carol II, transferred his dictatorial powers to General Ion Antonescu on Sept. 4, 1940, and abdicated his crown in favour of his young son Michael two days later. Antonescu had already repeated the request for a German military mission, which arrived in Bucharest on October 12.

Though Hitler had apprised the Italian foreign minister, Galeazzo Ciano, of his intention to send a military mission to Romania, Ciano had not apprised Mussolini. So, since the latter's Balkan ambitions had been continually restrained by Hitler, particularly with regard to Yugoslavia, the sudden news of the mission annoyed him. On Oct. 28, 1940, therefore, having given Hitler only the barest hints of his project, Mussolini launched seven Italian divisions (155,000 men) from Albania into a separate war of his own against Greece.

Italy's attack on Greece

The result was exasperating for Hitler. His ally's forces were not only halted by the Greeks, a few miles over the border, on Nov. 8, 1940, but were also driven back by General Alexandros Papagos' counteroffensive of November 14, which was to put the Greeks in possession of one-third of Albania by mid-December. Moreover, British troops landed in Crete, and some British aircraft were sent to bases near Athens, whence they might have attacked the Romanian oil fields. Lastly, the success of the Greeks caused Yugoslavia and Bulgaria, who had hitherto been attentive to overtures from the Axis powers, to revert to a strictly neutral policy.

Anticipating Mussolini's appeal for German help in his "separate" or "parallel" war, Hitler in November 1940 drew Hungary, Romania, and Slovakia successively into the Axis, or Tripartite, Pact that Germany, Italy, and Japan had concluded on September 27 (see below); and he also obtained Romania's assent to the assembling of German troops in the south of Romania for an attack on Greece through Bulgaria. Hungary consented to the transit of these troops through its territory lest Romania take Hungary's place in Germany's favour and so be secured in possession of the Transylvanian lands left to it by the Vienna Award. Bulgaria, however, for fear of Soviet reaction, on the one hand, and of Turkish, on the other (Turkey had massed 28 divisions in Thrace when Italy attacked Greece), delayed its adhesion to the Axis until March 1, 1941. Only thereafter, on March 18, did the Yugoslav regent, Prince Paul, and his ministers Dragiša Cvetković and Aleksandar Cincar-Marković agree to Yugoslavia's adhesion to the Axis.

Meanwhile, the German 12th Army had crossed the Danube from Romania into Bulgaria on March 2, 1941. Consequently, in accordance with a Greco-British agreement of February 21, a British expeditionary force of 58,000 men from Egypt landed in Greece on March 7, to occupy the Olympus–Vermion line. Then, on March 27, 1941, two days after the Yugoslav government's signature, in Vienna, of its adhesion to the Axis Pact, a group of Yugoslav Army officers, led by General Dušan Simović, executed a coup d'état in Belgrade, overthrowing the regency in favour of the 17-year-old king Peter II and reversing the former government's policy.

The Yugoslav coup d'état and the Battle of Cape Matapan

Almost simultaneously with the Belgrade coup d'état, the decisive Battle of Cape Matapan took place between the British and Italian fleets in the Mediterranean, off the Peloponnesian mainland northwest of Crete. Italo-British naval hostilities in the Mediterranean area since June 1940 had comprised only one noteworthy action: the sinking in November at the Italian naval base of Taranto of three battleships by aircraft from the British carrier *Illustrious.* In March 1941, however, some Italian

naval forces, including the battleship *Vittorio Veneto,* with several cruisers and destroyers, set out to threaten British convoys to Greece; and British forces, including the battleships *Warspite, Valiant,* and *Barham* and the aircraft carrier *Formidable,* likewise with cruisers and destroyers, were sent to intercept them. When the forces met in the morning of March 28, off Cape Matapan, the *Vittorio Veneto* opened fire on the lighter British ships but was soon trying to escape from the engagement, for fear of the torpedo aircraft from the *Formidable.* The battle then became a pursuit, which lasted long into the night. Finally, though the severely damaged *Vittorio Veneto* made good her escape, the British sank three Italian cruisers and two destroyers. The Italian Navy made no more surface ventures into the eastern Mediterranean.

The German attack on Greece, scheduled for April 1, 1941, was postponed for a few days when Hitler, because of the Belgrade coup d'état, decided that Yugoslavia was to be destroyed at the same time. While Great Britain's efforts to draw Yugoslavia into the Greco-British defensive system were fruitless, Germany began canvasing allies for its planned invasion of Yugoslavia and Greece. Italy agreed to collaborate in the attack, and Hungary and Bulgaria agreed to send troops to occupy the territories that they coveted as soon as the Germans should have destroyed the Yugoslav state.

On April 6, 1941, the Germans, with 24 divisions and 1,200 tanks, invaded both Yugoslavia (which had 32 divisions) and Greece (which had 15 divisions). The operations were conducted in the same way as Germany's previous blitzkrieg campaigns. While massive air raids struck Belgrade, List's 12th Army drove westward and southward from the Bulgarian frontiers, Kleist's armoured group northwestward from Sofia, and Weichs's 2nd Army southward from Austria and from western Hungary. The 12th Army's advance through Skopje to the Albanian border cut communications between Yugoslavia and Greece in two days; Niš fell to Kleist on April 9, Zagreb to Weichs on April 10; and on April 11 the Italian 2nd Army (comprising 15 divisions) advanced from Istria into Dalmatia. After the fall of Belgrade to the German forces from bases in Romania (April 12), the remnant of the Yugoslav Army—whose only offensive, in northern Albania, had collapsed—was encircled in Bosnia. Its capitulation was signed, in Belgrade, on April 17.

Yugoslavia and Greece invaded by the Germans

In Greece, meanwhile, the Germans took Salonika (Thessaloníki) on April 9, 1941, and then initiated a drive toward Ioánnina (Yannina), thus severing communication between the bulk of the Greek Army (which was on the Albanian frontier) and its rear. The isolated main body capitulated on April 20, the Greek Army as a whole on April 22. Two days later the pass of Thermopylae, defended by a British rear guard, was taken by the Germans, who entered Athens on April 27. All mainland Greece and all the Greek Aegean islands except Crete were under German occupation by May 11, the Ionian islands under Italian. The remainder of Britain's 50,000-man force in Greece was hastily evacuated with great difficulty after leaving all of their tanks and other heavy equipment behind.

The campaign against Yugoslavia brought 340,000 soldiers of the Yugoslav Army into captivity as German prisoners of war. In the campaign against Greece the Germans took 220,000 Greek and 20,000 British or Commonwealth prisoners of war. The combined German losses in the Balkan campaigns were about 2,500 dead, 6,000 wounded, and 3,000 missing.

German airborne troops began to land in Crete on May 20, 1941, at Máleme, in the Canea-Suda area, at Réthimnon, and at Iráklion. Fighting, on land and on the sea, with heavy losses on both sides, went on for a week before the Allied commander in chief, General Bernard Cyril Freyberg of the New Zealand Expeditionary Force, was authorized to evacuate the island. The last defenders were overwhelmed at Réthimnon on May 31. The prisoners of war taken by the Germans in Crete numbered more than 15,000 British or Commonwealth troops, besides the Greeks taken. In battles around the island, German air attacks sank three light cruisers and six destroyers of the British Mediterranean fleet and damaged three battleships,

one aircraft carrier, six light cruisers, and five destroyers.

Both the Yugoslav and the Greek royal governments went into exile on their armies' collapse. The Axis powers were left to dispose as they would of their conquests. Yugoslavia was completely dissolved: Croatia, the independence of which had been proclaimed on April 10, 1941, was expanded to form Great Croatia, which included Srem (Syrmia, the zone between the Sava and the Danube south of the Drava confluence) and Bosnia and Hercegovina; most of Dalmatia was annexed to Italy; Montenegro was restored to independence; Yugoslav Macedonia was partitioned between Bulgaria and Albania; Slovenia was partitioned between Italy and Germany; the Baranya triangle and the Bačka went to Hungary; the Banat and Serbia were put under German military administration. Of the independent states, Great Croatia, ruled by Ante Pavelić's nationalist Ustaše ("Insurgents"), and Montenegro were Italian spheres of influence, although German troops still occupied the eastern part of Great Croatia. A puppet government of Serbia was set up by the Germans in August 1941.

Dissolution of Yugoslavia

While Bulgarian troops occupied eastern Macedonia and most of western Thrace, the rest of mainland Greece, theoretically subject to a puppet government in Athens, was militarily occupied by the Italians except for three zones, namely the Athens district, the Salonika district, and the Dimotika strip of Thrace, which the German conquerors reserved for themselves. The Germans also remained in occupation of Lesbos, Chios, Samos, Melos, and Crete.

OTHER FRONTS, 1940–41

Egypt and Cyrenaica, 1940–summer 1941. The contemporary course of events in the Balkans, described above, nullified the first great victory won by British land forces in World War II, which took place in North Africa. When Italy declared war against Great Britain in June 1940, it had nearly 300,000 men under Marshal Rodolfo Graziani in Cyrenaica (present-day Libya), to confront the 36,000 troops whom the British commander in chief in the Middle East, General Sir Archibald Wavell, had in Egypt to protect the North African approaches to the Suez Canal. Between these forces lay the Western Desert, in which the westernmost position actually held by the British was Mersa Matruh (Marsā Maṭrūḥ), 120 miles east of the Cyrenaican frontier. The Italians in September 1940 occupied Sīdī Barrānī, 170 miles west of Mersa Matruh; but, after settling six divisions into a chain of widely separated camps, they did nothing more for weeks, and during that time Wavell received some reinforcements.

Wavell, whose command included not only Egypt but also the East African fronts against the Italians, decided to strike first in North Africa. On Dec. 7, 1940, some 30,000 men, under Major General Richard Nugent O'Connor, advanced westward, from Mersa Matruh, against 80,000 Italians; but, whereas the Italians at Sīdī Barrānī had only 120 tanks, O'Connor had 275. Having passed by night through a gap in the chain of forts, O'Connor's forces stormed three of the Italian camps, while the 7th Armoured Division was already cutting the Italians' road of retreat along the coast to the west. On December 10 most of the positions closer to Sīdī Barrānī were overrun; and on December 11 the reserve tanks made a further enveloping bound to the coast beyond Buqbuq, intercepting a large column of retreating Italians. In three days the British had taken nearly 40,000 prisoners.

Wavell's offensive

Falling back across the frontier into Cyrenaica, the remnant of the Italian forces from Sīdī Barrānī shut itself up in the fortress of Bardia (Bardīyah), which O'Connor's tanks speedily isolated. On Jan. 3, 1941, the British assault on Bardia began, and three days later the whole garrison of Bardia surrendered—45,000 men. The next fortress to the west, Tobruk (Ṭubruq), was assaulted on January 23 and captured the next day (30,000 more prisoners).

To complete their conquest of Cyrenaica, it remained for the British to take the port of Benghazi. On Feb. 3, 1941, however, O'Connor learned that the Italians were about to abandon Benghazi and to retreat westward down the coast road to Agheila (al-'Uqaylah). Thereupon he boldly ordered the 7th Armoured Division to cross the desert

hinterland and intercept the Italian retreat by cutting the coast road well to the east of Agheila. On February 5, after an advance of 170 miles in 33 hours, the British were blocking the Italians' line of retreat south of Beda Fomm (Bayḍā' Fumm); and in the morning of February 6, as the main Italian columns appeared, a day of battle began. Though the Italians had, altogether, nearly four times as many cruiser tanks as the British, by the following morning 60 Italian tanks had been crippled, 40 more abandoned, and the rest of Graziani's army was surrendering in crowds. The British, only 3,000 strong and having lost only three of their 29 tanks, took 20,000 prisoners, 120 tanks, and 216 guns.

The British, having occupied Benghazi on February 6 and Agheila on February 8, could now have pushed on without hindrance to Tripoli, but the chance was foregone: the Greek government had accepted Churchill's reiterated offer of British troops to be sent to Greece from Egypt, which meant a serious reduction of British strength in North Africa.

The reduction was to have serious consequences, because on February 6, the very day of Beda Fomm, a young general, Erwin Rommel, had been appointed by Hitler to command two German mechanized divisions that were to be sent as soon as possible to help the Italians. Arriving in Tripolitania, Rommel decided to try an offensive with what forces he had. Against the depleted British strength, he was rapidly and brilliantly successful. After occupying Agheila with ease on March 24 and Mersa Bréga (Qasr al-Burayqah) on March 31, he resumed his advance on April 2—despite orders to stand still for two months—with 50 tanks backed by two new Italian divisions. The British evacuated Benghazi the next day and began a precipitate retreat into Egypt, losing great numbers of their tanks on the way (a large force of armour, surrounded at Mechili, had to surrender on April 7). By April 11 all Cyrenaica except Tobruk had been reconquered by Rommel's audacious initiative.

Rommel's counterattack

Tobruk, garrisoned mainly by the 9th Australian Division, held out against siege; and Rommel, though he defeated two British attempts to relieve the place (May and June 1941), was obliged to suspend his offensive on the Egyptian frontier, since he had overstretched his supply lines.

East Africa. Wavell, the success of whose North African strategy had been sacrificed to Churchill's recurrent fantasy of creating a Balkan front against Germany (Greece in 1941 was scarcely less disastrous for the British than the Dardanelles in 1915), nevertheless enjoyed one definitive triumph before Churchill, doubly chagrined at having lost Cyrenaica for Greece's sake and Greece for no advantage at all, removed him, in the summer of 1941, from his command in the Middle East. That triumph was the destruction of Italian East Africa and the elimination, thereby, of any threat to the Suez Canal from the south or to Kenya from the north.

In August 1940 Italian forces mounted a full-scale offensive and overran British Somaliland. Wavell, however, was already assured of the collaboration of the former Ethiopian emperor Haile Selassie in raising the Ethiopians in patriotic revolt against the Italians; and, whereas in June he had disposed only of meagre resources against the 200,000 men and 325 aircraft under the Duca d'Aosta, Amedeo di Savoia, his troops in the Sudan were reinforced by two Indian divisions before the end of the year. After Haile Selassie and a British major, Orde Wingate, with two battalions of Ethiopian exiles, had crossed the Sudanese frontier directly into Ethiopia, General William Platt and the Indian divisions invaded Eritrea on Jan. 19, 1941 (the Italians had already abandoned Kassala); and, almost simultaneously, British troops from Kenya, under General Alan Cunningham, advanced into Italian Somaliland.

Platt's drive eastward into Eritrea was checked on February 5, at Keren, where the best Italian troops, under General Nicolangelo Carnimeo, put up a stiff defense facilitated by a barrier of cliffs. But when Keren fell on March 26, Platt's way to Asmara (Asmera), to Massawa (Mitsiwa), and then from Eritrea southward into Ethiopia was comparatively easy. Meanwhile, Cunningham's troops

were advancing northward into Ethiopia; and on April 6 they entered the Ethiopian capital, Addis Ababa. Finally, the Duca d'Aosta was caught between Platt's column and Cunningham's; and at Amba Alaji, on May 20, he and the main body of his forces surrendered.

Iraq and Syria, 1940–41. In 1940 Prince 'Abd al-Ilāh, regent of Iraq for King Fayṣal, had a government divided within itself about the war; he himself and his foreign minister, Nuri as-Said, were pro-British, but his prime minister, Rashid Ali al-Gailani, had pro-German leanings. Having resigned office in January 1941, Rashid Ali on April 3 seized power in Baghdad with help from some army officers and announced that the temporarily absent regent was deposed. The British, ostensibly exercising their right under the Anglo-Iraqi Treaty of 1930 to move troops across Iraqi territory, landed troops at Basra on April 19 and rejected Iraqi demands that these troops be sent on into Palestine before any further landings. Iraqi troops were then concentrated around the British air base at Ḥabbāniyah, west of Baghdad; and on May 2 the British commander there opened hostilities, lest the Iraqis should attack first. Having won the upper hand at Ḥabbāniyah and been reinforced from Palestine, the British troops from the air base marched on Baghdad; and on May 30 Rashid Ali and his friends took refuge in Iran. 'Abd al-Ilāh was reinstated as regent; Nuri became prime minister; and the British military presence remained to uphold them.

German military supplies for Rashid Ali were dispatched too late to be useful to him; but they reached Iraq via Syria, whose high commissioner, General H.-F. Dentz, was a nominee of the Vichy government of France. Lest Syria and Lebanon should fall altogether under Axis control, the British decided to intervene there. Consequently, Free French forces, under General Georges Catroux, with British, Australian, and Indian support, were sent into both countries from Palestine on June 8, 1941; and a week later British forces invaded Syria from Iraq. Dentz's forces put up an unexpectedly stiff resistance, particularly against the Free French, but were finally obliged to capitulate: an armistice was signed at Acre on July 14. By an arrangement of July 25 the Free French retained territorial command in Syria and Lebanon subject to strategic control by the British.

The beginning of lend-lease. On June 10, 1940, when Italy entered the war on the German side and when the fall of France was imminent, U.S. president Franklin D. Roosevelt declared that the United States would "extend to the opponents of force the material resources of this nation." After France fell, he pursued this policy by aiding the British in their struggle against Germany. Roosevelt arranged for the transfer of surplus American matériel to the British under various arrangements, including the exchange of 50 old American destroyers for certain British-held Atlantic bases, and he facilitated the placing of British orders for munitions in the United States. The British decided to rely on the United States unreservedly and without regard to their ability to pay. By December 1940 they had already placed orders for war materials that were far more than they could possibly muster the dollar exchange to finance.

Churchill suggested the concept of lend-lease to Roosevelt in December 1940, proposing that the United States provide war materials, foodstuffs, and clothing to the democracies (and particularly to Great Britain). Roosevelt assented, and a bill to achieve this purpose was passed by the Congress in early 1941. The Lend-Lease Act not only empowered the president to transfer defense materials, services, and information to any foreign government whose defense he deemed vital to that of the United States, but also left to his discretion what he should ask in return. An enormous grant of power, it gave Roosevelt virtually a free hand to pursue his policy of material aid to the "opponents of force." Congress appropriated funds generously, amounting to almost $13,000,000,000 by November 1941. Other countries besides Britain began receiving lend-lease aid by this time, including China and the Soviet Union. From the time of the German invasion of the U.S.S.R., Roosevelt had been clearly determined to aid the Soviet Union, but the American public's suspicions

of Communism delayed his declaring that country eligible for lend-lease until November 1941. American deliveries of aircraft, tanks, and other supplies to the U.S.S.R. began shortly thereafter.

The Atlantic and the Mediterranean, 1940–41. At the outbreak of World War II, the primary concerns of the British Navy were to defend Great Britain from invasion and to retain command of the ocean trading routes, both in order to protect the passage of essential supplies of food and raw materials for Britain and to deny the trading routes to the Axis powers, thus drawing tight once again the blockade that had proved so successful during World War I. Britain had adequate forces of battleships, aircraft carriers, cruisers, and other ships to fulfill these tasks.

The German Navy's role was to protect Germany's coasts, to defend its sea communications and to attack those of the Allies', and to support land and air operations. These modest goals were in keeping with Germany's position as the dominant land-based power in continental Europe. Germany's main naval weapon during the war was to be the submarine, or U-boat, with which it attacked Allied shipping much as it had in World War I.

German control of the Biscay ports after the fall of France in June 1940 provided the U-boats with bases from which they could infest the Atlantic without having to pass either through the Channel or around the north of the British Isles at the end of every sortie. Thenceforward, so long as naval escorts for outgoing convoys from the British Isles could go only 200 or 300 miles out to sea before having to turn back to escort incoming convoys, the U-boats had a very wide field for free-ranging activity: sinkings rose sharply from 55,580 tons in May 1940 to 352,407 tons in October, achieved mainly by solitary attacks by single U-boats at night. But the beginning of lend-lease and the freeing of British warships after the German invasion threat waned enabled the British to escort their convoys for 400 miles by October 1940 and halfway across the Atlantic by April 1941. Since air cover for shipping could also be provided from the British Isles, from Canada, and from Iceland, the Atlantic space left open to the U-boats was reduced by May 1941 to a width of only 300 miles. Moreover, British surface vessels had the ASDIC (Anti-Submarine Detection Investigation Committee) device to detect submerged U-boats. By the spring of 1941, under the guidance of Admiral Karl Dönitz, the U-boat commanders were changing their tactic of individual operation to one of wolf-pack attacks: groups of U-boats, disposed in long lines, would rally when one of them by radio signaled a sighting and overwhelm the convoy by weight of numbers. Between July and December 1941 the German U-boat strength was raised from 65 to more than 230.

Furthermore, the German surface fleet became more active against Allied seaborne trade. Six armed German raiders disguised as merchantmen, with orders to leave convoys alone and to confine their attacks to unescorted ships, roamed the oceans with practical impunity from the spring of 1940 and had sunk 366,644 tons of shipping by the end of the year. German battleships—the *Admiral Scheer,* the *Admiral Hipper,* the *Scharnhorst,* and the *Gneisenau*—one after another began similar raiding operations, with considerable success, from October 1940; and in May 1941 a really modern battleship, the *Bismarck,* and a new cruiser, the *Prinz Eugen,* put out to sea from Germany. The *Bismarck* and the *Prinz Eugen,* however, were located by British reconnaissance in the North Sea near Bergen, and an intensive hunt for them was immediately set in motion. Tracked from a point northwest of Iceland by two British cruisers, the two German ships were engaged on May 24 by the battle cruiser *Hood* and by the new battleship *Prince of Wales;* and, though the *Hood* was sunk, the *Bismarck* 's fuel supply was put out of action, so that her commander, Admiral Günther Lütjens, decided to make for the French coast. Separating from the *Prinz Eugen* (which escaped), the *Bismarck* threw off her pursuers early on May 25 but was sighted again the next day some 660 miles west of Brest. Paralyzed by torpedo aircraft from the *Ark Royal,* she was bombarded and sunk by the *King George V,* the *Rodney,* and the *Dorsetshire* on May 27.

In the Mediterranean the year 1941 ended with some naval triumphs for the Axis: U-boats torpedoed the *Ark Royal* on November 13 and the *Barham* 12 days later; Italian frogmen, entering the harbour of Alexandria, on December 19 crippled the battleships *Queen Elizabeth* and *Valiant;* and two British cruisers and a destroyer were also sunk in Mediterranean waters in December.

German strategy, 1939–42. German strategy in World War II is wholly intelligible only if Hitler's far-reaching system of power politics and his racist ideology are borne in mind. Since the 1920s his program had been first to win power in Germany proper, next to consolidate Germany's domination over Central Europe, and then to raise Germany to the status of a world power by two stages: (1) the building up of a continental empire embracing all Europe, including the European portion of the Soviet Union, and (2) the attainment for Germany of equal rank with the British Empire, Japan, and the United States—the only world powers to be left after the elimination of France and the U.S.S.R.—through the acquisition of colonies in Africa and the construction of a strong fleet with bases on the Atlantic. In the succeeding generation Hitler foresaw a decisive conflict between Germany and the United States, during which he hoped that Great Britain would be Germany's ally.

The conquest of the European part of the Soviet Union, which in Hitler's calendar was dated approximately for 1943–45, was to be preceded, he thought, by short localized campaigns elsewhere in Europe to provide a strategic shield and to secure Germany's rear for the great expedition of conquest in the East, which was also bound up with the extermination of the Jews. The most important of the localized campaigns would be that against France. While this European program remained unfulfilled, it was imperative to avoid any world war, since only after the German Reich had come to dominate the whole European continent would it have the economic base and the territorial extent that were prerequisite for success in a great war, especially against maritime world powers.

Hitler had always contemplated the overthrow of the Soviet regime, and though he had congratulated himself on the German-Soviet Nonaggression Pact of 1939 as a matter of expediency, anti-Bolshevism had remained his most profound emotional conviction. His feelings had been stirred up afresh by the Soviet occupation of the Baltic states and of Bessarabia and northern Bukovina in June 1940 and by the consequent proximity of Soviet forces to the Romanian oil fields on which Germany depended. Hitler became acutely suspicious of the intentions of the Soviet leader, Joseph Stalin, and he began to feel that he could not afford to wait to complete the subjugation of western Europe before dealing with the Soviet Union. Hitler and his generals had originally scheduled the invasion of the U.S.S.R. for mid-May 1941, but the unforeseen necessity of invading Yugoslavia and Greece in April of that year had forced them to postpone the Soviet campaign to late June. The swiftness of Hitler's Balkan victories enabled him to keep to this revised timetable, but the five weeks' delay shortened the time for carrying out the invasion of the U.S.S.R. and was to prove the more serious because in 1941 the Russian winter would arrive earlier than usual. Nevertheless, Hitler and the heads of the Oberkommando des Heeres (OKH, or German Army High Command), namely the army commander in chief Werner von Brauchitsch and the army general staff chief Franz Halder, were convinced that the Red Army could be defeated in two or three months, and that, by the end of October, the Germans would have conquered the whole European part of Russia and the Ukraine west of a line stretching from Archangel to Astrakhan. The invasion of the Soviet Union was given the code name "Operation Barbarossa."

INVASION OF THE SOVIET UNION, 1941

The German attack on the Soviet Union, 1941. For the campaign against the Soviet Union, the Germans allotted almost 150 divisions containing a total of about 3,000,000 men. Among these were 19 panzer divisions, and in total the "Barbarossa" force had about 3,000 tanks, 7,000 artillery pieces, and 2,500 aircraft. It was in effect the largest and most powerful invasion force in human history. The Germans' strength was further increased by more than 30 divisions of Finnish and Romanian troops.

The Soviet Union had twice or perhaps three times the number of both tanks and aircraft as the Germans had, but their aircraft were mostly obsolete. The Soviet tanks were about equal to those of the Germans, however. A greater hindrance to Hitler's chances of victory was that the German intelligence service underestimated the troop reserves that Stalin could bring up from the depths of the U.S.S.R. The Germans correctly estimated that there were about 150 divisions in the western parts of the U.S.S.R. and reckoned that 50 more might be produced. But the Soviets actually brought up more than 200 fresh divisions by the middle of August, making a total of 360. The consequence was that, though the Germans succeeded in shattering the original Soviet armies by superior technique, they then found their path blocked by fresh ones. The effects of the miscalculations were increased because much of August was wasted while Hitler and his advisers were having long arguments as to what course they should follow after their initial victories. Another factor in the Germans' calculations was purely political, though no less mistaken; they believed that within three to six months of their invasion, the Soviet regime would collapse from lack of domestic support.

The German attack on the Soviet Union was to have an immediate and highly salutary effect on Great Britain's situation. Until then Britain's prospects had appeared hopeless in the eyes of most people except the British themselves; and the government's decision to continue the struggle after the fall of France and to reject Hitler's peace offers could spell only slow suicide unless relief came from either the United States or the U.S.S.R. Hitler brought Great Britain relief by turning eastward and invading the Soviet Union just as the strain on Britain was becoming severe.

On June 22, 1941, the German offensive was launched by three army groups under the same commanders as in the invasion of France in 1940: on the left (north), an army group under Leeb struck from East Prussia into the Baltic states toward Leningrad; on the right (south), another army group, under Rundstedt, with an armoured group under Kleist, advanced from southern Poland into the Ukraine against Kiev, whence it was to wheel southeastward to the coasts of the Black Sea and the Sea of Azov; and in the centre, north of the Pripet Marshes, the main blow was delivered by Bock's army group, with one armoured group under Guderian and another under Hoth, thrusting northeastward at Smolensk and Moscow.

The invasion along a 1,800-mile front took the Soviet leadership completely by surprise and caught the Red Army in an unprepared and partially demobilized state. Piercing the northern border, Guderian's tanks raced 50 miles beyond the frontier on the first day of the invasion and were at Minsk, 200 miles beyond it, on June 27. At Minsk they converged with Hoth's tanks, which had pierced the opposite flank, but Bock's infantry could not follow up quickly enough to complete the encirclement of the Soviet troops in the area; though 300,000 prisoners were taken in the salient, a large part of the Soviet forces was able to escape to the east. The Soviet armies were clumsily handled and frittered their tank strength away in piecemeal action like that of the French in 1940. But the isolated Soviet troops fought with a stubbornness that the French had not shown, and their resistance imposed a brake by continuing to block road centres long after the German tide had swept past them. The result was similar when Guderian's tanks, having crossed the Dnepr River on July 10, entered Smolensk six days later and converged with Hoth's thrust through Vitebsk: 200,000 Soviet prisoners were taken; but some Soviet forces were withdrawn from the trap to the line of the Desna, and a large pocket of resistance lay behind the German armour. By mid-July, moreover, a series of rainstorms were turning the sandy Russian roads into clogging mud, over which the wheeled vehicles of the German transport behind the tanks could make only very slow progress. The Germans also began

to be hampered by the scorched earth policy adopted by the retreating Soviets. The Soviet troops burned crops, destroyed bridges, and evacuated factories in the face of the German advance. Entire steel and munitions plants in the westernmost portions of the U.S.S.R. were dismantled and shipped by rail to the east, where they were put back into production. The Soviets also destroyed or evacuated most of their rolling stock (railroad cars), thus depriving the Germans of the use of the Soviet rail system, since Soviet railroad track was of a different gauge than German track and German rolling stock was consequently useless on it.

Nevertheless, by mid-July the Germans had advanced more than 400 miles and were only 200 miles from Moscow. They still had ample time to make decisive gains before the onset of winter, but they lost the opportunity, primarily because of arguments throughout August between Hitler and the OKH about the destination of the next thrusts thence: whereas the OKH proposed Moscow as the main objective, Hitler wanted the major effort to be directed southeastward, through the Ukraine and the Donets Basin into the Caucasus, with a minor swing northwestward against Leningrad (to converge with Leeb's army group).

In the Ukraine, meanwhile, Rundstedt and Kleist had made short work of the foremost Soviet defenses, stronger though the latter had been. A new Soviet front south of Kiev was broken by the end of July; and in the next fortnight the Germans swept down to the Black Sea mouths of the Bug and Dnepr rivers—to converge with Romania's simultaneous offensive. Kleist was then ordered to wheel northward from the Ukraine, Guderian southward from Smolensk, for a pincer movement around the Soviet forces behind Kiev; and by the end of September the claws of the encircling movement had caught 520,000 men. These gigantic encirclements were partly the fault of inept Soviet high commanders and partly the fault of Stalin, who as commander in chief stubbornly overrode the advice of his generals and ordered his armies to stand and fight instead of allowing them to retreat eastward and regroup in preparation for a counteroffensive.

Winter was approaching, and Hitler stopped Leeb's northward drive on the outskirts of Leningrad. He ordered Rundstedt and Kleist, however, to press on from the Dnepr toward the Don and the Caucasus; and Bock was to resume the advance on Moscow.

Bock's renewed advance on Moscow began on Oct. 2, 1941. Its prospects looked bright when Bock's armies brought off a great encirclement around Vyazma, where 600,000 more Soviet troops were captured. That left the Germans momentarily with an almost clear path to Moscow. But the Vyazma battle had not been completed until late October; the German troops were tired, the country became a morass as the weather got worse, and fresh Soviet forces appeared in the path as they plodded slowly forward. Some of the German generals wanted to break off the offensive and to take up a suitable winter line. But Bock wanted to press on, believing that the Soviets were on the verge of collapse, while Brauchitsch and Halder tended to agree with his view. As that also accorded with Hitler's desire, he made no objection. The temptation of Moscow, now so close in front of their eyes, was too great for any of the topmost leaders to resist. On December 2 a further effort was launched, and some German detachments penetrated into the suburbs of Moscow; but the advance as a whole was held up in the forests covering the capital. The stemming of this last phase of the great German offensive was partly due to the effects of the Russian winter, whose subzero temperatures were the most severe in several decades. In October and November a wave of frostbite cases had decimated the ill-clad German troops, for whom provisions of winter clothing had not been made, while the icy cold paralyzed the Germans' mechanized transport, tanks, artillery, and aircraft. The Soviets, by contrast, were well clad and tended to fight more effectively in winter than did the Germans. By this time German casualties had mounted to levels that were unheard of in the campaigns against France and the Balkans; by November the Germans had suffered about 730,000 casualties.

In the south, Kleist had already reached Rostov-on-Don, gateway to the Caucasus, on November 22, but had exhausted his tanks' fuel in doing so. Rundstedt, seeing the place to be untenable, wanted to evacuate it but was overruled by Hitler. A Soviet counteroffensive recaptured Rostov on November 28, and Rundstedt was relieved of his command four days later. The Germans, however, managed to establish a front on the Mius River—as Rundstedt had recommended.

The Soviet counter-offensives

As the German drive against Moscow slackened, the Soviet commander on the Moscow front, General Georgy Konstantinovich Zhukov, on December 6 inaugurated the first great counteroffensive with strokes against Bock's right in the Elets (Yelets) and Tula sectors south of Moscow and against his centre in the Klin and Kalinin sectors to the northwest. Levies of Siberian troops, who were extremely effective fighters in cold weather, were used for these offensives. There followed a blow at the German left, in the Velikie Luki sector; and the counteroffensive, which was sustained throughout the winter of 1941–42, soon took the form of a triple convergence toward Smolensk.

These Soviet counteroffensives tumbled back the exhausted Germans, lapped around their flanks, and produced a critical situation. From generals downward, the invaders were filled with ghastly thoughts of Napoleon's retreat from Moscow. In that emergency Hitler forbade any retreat beyond the shortest possible local withdrawals. His decision exposed his troops to awful sufferings in their advanced positions facing Moscow, for they had neither the clothing nor the equipment for a Russian winter campaign; but if they had once started a general retreat it might easily have degenerated into a panic-stricken rout.

The Red Army's winter counteroffensive continued for more than three months after its December launching, though with diminishing progress. By March 1942 it had advanced more than 150 miles in some sectors. But the Germans maintained their hold on the main bastions of their winter front—such towns as Schlüsselburg, Novgorod, Rzhev, Vyazma, Bryansk, Orël (Oryol), Kursk, Kharkov, and Taganrog—despite the fact that the Soviets had often advanced many miles beyond these bastions, which were in effect cut off. In retrospect, it became clear that Hitler's veto on any extensive withdrawal worked out in such a way as to restore the confidence of the German troops and probably saved them from a widespread collapse. Nevertheless, they paid a heavy price indirectly for that rigid defense. One immediate handicap was that the strength of the Luftwaffe was drained in the prolonged effort to maintain supplies by air, under winter conditions, to the garrisons of these more or less isolated bastion towns. The tremendous strain of that winter campaign, on armies which had not been prepared for it, had other serious effects. Before the winter ended, many German divisions were reduced to barely a third of their original strength, and they were never fully built up again.

The German plan of campaign had begun to miscarry in August 1941, and its failure was patent when the Soviet counteroffensive started. Nevertheless, having dismissed Brauchitsch and appointed himself army commander in chief in December, Hitler persisted in overruling the tentative opposition of the general staff to his strategy.

The first three months of the German–Soviet conflict produced cautious rapprochements between the U.S.S.R. and Great Britain and between the U.S.S.R. and the United States. The Anglo-Soviet agreement of July 12, 1941, pledged the signatory powers to assist one another and to abstain from making any separate peace with Germany. On Aug. 25, 1941, British and Soviet forces jointly invaded Iran, to forestall the establishment of a German base there and to divide the country into spheres of occupation for the duration of the war; and late in September—at a conference in Moscow—Soviet, British, and U.S. representatives formulated the monthly quantities of supplies, including aircraft, tanks, and raw materials, that Great Britain and the United States should try to furnish to the Soviet Union.

The critical situation on the Eastern Front did not deter Hitler from declaring Germany to be at war with the United States on Dec. 11, 1941, after the Japanese attack

on the U.S., British, and Dutch positions in the Pacific and in the Far East (see below), since this extension of hostilities did not immediately commit the German land forces to any new theatre but at the same time had the merit of entitling the German Navy to intensify the war at sea.

THE WAR IN THE PACIFIC, 1938–41

The war in China, 1937–41. In 1931–32 the Japanese had invaded Manchuria (Northeast China) and, after overcoming ineffective Chinese resistance there, had created the Japanese-controlled puppet state of Manchukuo. In the following years the Nationalist government of China, headed by Chiang Kai-shek, temporized in the face of Japanese military and diplomatic pressures and instead waged an internal war against the Chinese Communists, led by Mao Zedong, who were based in Shensi Province in north-central China. Meanwhile, the Japanese began a military buildup in North China proper, which in turn stimulated the formation of a unified resistance by the Nationalists and the Communists. Overt hostilities between Japan and China began after the Marco Polo Bridge incident of July 7, 1937, when shots were exchanged between Chinese and Japanese troops on the outskirts of Peking. Open fighting broke out in that area, and in late July the Japanese captured the Peking-Tientsin area. Thereupon full-scale hostilities began between the two nations. The Japanese landed near Shanghai, at the mouth of the Yangtze River, and took Shanghai in November and the Chinese capital, Nanking, in December 1937. Chiang Kai-shek moved his government to Han-k'ou (one of the Wu-han cities), which lay 435 miles west of Shanghai along the Yangtze. The Japanese also pushed southward and westward from the Peking area into Hopeh and Shansi provinces. In 1938 the Japanese launched several ambitious military campaigns that brought them deep into the heart of central China. They advanced to the northeast and west from Nanking, taking Suchow and occupying the Wu-han cities. The Nationalists were forced to move their government to Chungking in Szechwan Province, about 500 miles west of the Wu-han cities. The Japanese also occupied Canton and several other coastal cities in South China in 1938.

Nationalist Chinese resistance to these Japanese advances was ineffective, primarily because the Nationalist leadership was still more interested in holding their forces in reserve for a future struggle with the Communists than in repelling the Japanese. By contrast, the Communists, from their base in north-central China, began an increasingly effective guerrilla war against the Japanese troops in Manchuria and North China. The Japanese needed large numbers of troops to maintain their hold on the immense Chinese territories and populations they controlled. Of the 51 infantry divisions making up the Japanese Army in 1941, 38 of them, comprising about 750,000 men, were stationed in China (including Manchuria).

Japanese policy, 1939–41. When war broke out in Europe in September 1939, the Japanese, despite a series of victorious battles, had still not brought their war in China to an end; on the one hand, the Japanese strategists had made no plans to cope with the guerrilla warfare pursued by the Chinese; on the other, the Japanese commanders in the field often disregarded the orders of the supreme command at the Imperial headquarters and occupied more Chinese territory than they had been ordered to take. Half of the Japanese Army was thus still tied down in China when the commitment of Great Britain and France to war against Germany opened up the prospect of wider conquests for Japan in Southeast Asia and in the Pacific. Japan's military ventures in China proper were consequently restricted rather more severely henceforth.

The German victories over The Netherlands and France in the summer of 1940 further encouraged the Japanese premier, Prince Konoe, to look southward at those defeated powers' colonies and also, of course, at the British and U.S. positions in the Far East. The island archipelago of the Dutch East Indies (now Indonesia) along with French Indochina and British-held Malaya contained raw materials (tin, rubber, petroleum) that were essential to Japan's industrial economy, and if Japan could seize these regions and incorporate them into the empire, it could make itself virtually self-sufficient economically and thus become the dominant power in the Pacific Ocean. Since Great Britain, single-handedly, was confronting the might of the Axis in Europe, the Japanese strategists had to reckon, probably, with the opposition of the United States to their plans for territorial aggrandizement. When Japanese troops entered northern Indochina in September 1940 (in pursuance of an agreement extorted in August from the Vichy government of France), the United States uttered a protest. Germany and Italy, by contrast, recognized Japan as the leading power in the Far East by concluding with it the Tripartite, or Axis, Pact of Sept. 27, 1940; negotiated by Japanese foreign minister Matsuoka Yosuke, the pact pledged its signatories to come to one another's help in the event of an attack "by a power not already engaged in war." Japan also concluded a neutrality pact with the U.S.S.R. on April 13, 1941.

Berlin–Rome–Tokyo Axis

On July 2, 1941, the Imperial Conference decided to press the Japanese advance southward even at the risk of war with Great Britain and the United States; and this policy was pursued even when Matsuoka was relieved of office a fortnight later. On July 26, in pursuance of a new agreement with Vichy France, Japanese forces began to occupy bases in southern Indochina.

This time the United States reacted vigorously, not only freezing Japanese assets under U.S. control but also imposing an embargo on supplies of oil to Japan. Dismay at the embargo drove the Japanese naval command, which had hitherto been more moderate than the army, into collusion with the army's extremism. When negotiations with the Dutch of Indonesia for an alternative supply of oil produced no satisfaction, the Imperial Conference on September 6, at the high command's insistence, decided that war must be undertaken against the United States and Great Britain unless an understanding with the United States could be reached in a few weeks' time.

General Tōjō Hideki, who succeeded Konoe as premier in mid-October 1941, continued the already desperate talks. The United States, however, persisted in making demands that Japan could not concede: renunciation of the Tripartite Pact (which would have left Japan diplomatically isolated); the withdrawal of Japanese troops from China and from Southeast Asia (a humiliating retreat from an overt commitment of four years' standing); and an open-door regime for trade in China. When Cordell Hull, the U.S. secretary of state, on Nov. 26, 1941, sent an abrupt note to the Japanese bluntly requiring them to evacuate China and Indochina and to recognize no Chinese regime other than that of Chiang Kai-shek, the Japanese could see no point in continuing the talks.

Since peace with the United States seemed impossible, Japan set in motion its plans for war, which would now necessarily be waged not only against the United States but also against Great Britain (the existing war effort of which depended on U.S. support and the Far Eastern colonies of which lay within the orbit of the projected Japanese expansion) and against the Dutch East Indies (the oil of which was essential to Japanese enterprises, even apart from geopolitical considerations).

The evolving Japanese military strategy was based on the peculiar geography of the Pacific Ocean and on the relative weakness and unpreparedness of the Allied military presence in that ocean. The western half of the Pacific is dotted with many islands, large and small, while the eastern half of the ocean is, with the exception of the Hawaiian Islands, almost devoid of landmasses (and hence of usable bases). The British, French, American, and Dutch military forces in the entire Pacific region west of Hawaii amounted to only about 350,000 troops, most of them lacking combat experience and being of disparate nationalities. Allied air power in the Pacific was weak and consisted mostly of obsolete planes. If the Japanese, with their large, well-equipped armies that had been battle-hardened in China, could quickly launch coordinated attacks from their existing bases on certain Japanese-mandated Pacific islands, on Formosa (Taiwan), and from Japan itself, they could overwhelm the Allied forces, overrun the entire western Pacific Ocean as well as Southeast Asia, and then develop

those areas' resources to their own military-industrial advantage. If successful in their campaigns, the Japanese planned to establish a strongly fortified defensive perimeter extending from Burma in the west to the southern rim of the Dutch East Indies and northern New Guinea in the south and sweeping around to the Gilbert and Marshall islands in the southeast and east. The Japanese believed that any American and British counteroffensives against this perimeter could be repelled, after which those nations would eventually seek a negotiated peace that would allow Japan to keep her newly won empire.

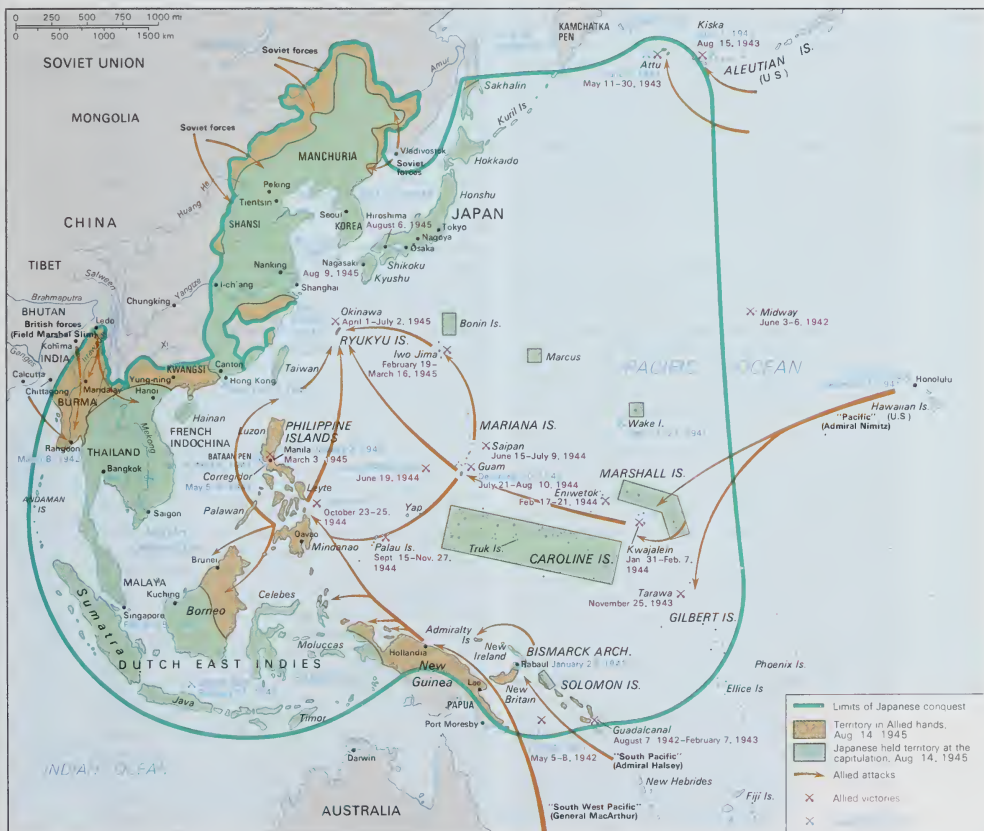
Until the end of 1940 the Japanese strategists had assumed that any new war to be waged would be against

Yamamo-
to's plan

a single enemy. When it became clear, in 1941, that the British and the Dutch as well as the Americans must be attacked, a new and daring war plan was successfully sponsored by the commander in chief of the Combined Fleet, Admiral Yamamoto Isoroku.

Yamamoto's plan prescribed two operations, together involving the whole strength of his navy, which was composed of the following ships: 10 battleships, six regular aircraft carriers, four auxiliary carriers, 18 heavy cruisers, 20 light cruisers, 112 destroyers, 65 submarines, and 2,274 combat planes. The first operation, to which all six regular aircraft carriers, two battleships, three cruisers, and 11 destroyers were allocated, was to be a surprise attack, scheduled for December 7 (December 8 by Japanese time),

on the main U.S. Pacific Fleet in its base at Pearl Harbor in the Hawaiian Islands. The rest of the Japanese Navy was to support the army in the "Southern Operation": 11 infantry divisions and seven tank regiments, assisted by 795 combat planes, were to undertake two drives, one from Formosa through the Philippines, the other from French Indochina and Hainan Island through Malaya, so as to converge on the Dutch East Indies, with a view to the capture of Java as the culmination of a campaign of 150 days—during which, moreover, Wake Island, Guam, the Gilbert Islands, and Burma should also have been secured as outer bastions, besides Hong Kong.

Pearl Harbor and the Japanese expansion, to July 1942. In accordance with Yamamoto's plan, the aircraft carrier strike force commanded by Admiral Nagumo Chuichi sailed westward undetected by any U.S. reconnaissance until it had reached a point 275 miles north of Hawaii. From there, on Sunday, Dec. 7, 1941, a total of about 360 aircraft, composed of dive-bombers, torpedo bombers, and a few fighters, was launched in two waves in the early morning against the giant U.S. naval base at Pearl Harbor. The base at that time was accommodating 70 U.S. fighting ships, 24 auxiliaries, and some 300 planes. The Americans were taken completely by surprise, and all eight battleships in the harbour were hit (though six were eventually repaired and returned to service); three cruisers, three destroyers, a minelayer, and other vessels


The Pacific Theatre of Operations, 1941–45.

were damaged; more than 180 aircraft were destroyed and others damaged (most while parked at airfields); and more than 2,330 troops were killed and over 1,140 wounded. Japanese losses were comparatively small. The Japanese attack failed in one crucial respect, however; the Pacific Fleet's three aircraft carriers were at sea at the time of the attack and escaped harm, and these were to become the nucleus of the United States' incipient naval defense in the Pacific. Pearl Harbor's shore installations and oil-storage facilities also escaped damage. The Pearl Harbor attack, unannounced beforehand by the Japanese as it was, unified the American public and swept away any remaining support for American neutrality in the war. On December 8 the U.S. Congress declared war on Japan with only one dissenting vote.

On the day of the attack, December 8 by local time, Formosa-based Japanese bombers struck Clark and Iba airfields in the Philippines, destroying more than 50 percent of the U.S. Army's Far East aircraft; and, two days later, further raids destroyed not only more U.S. fighters but also Cavite Naval Yard, likewise in the Philippines. Part of the U.S. Asiatic Fleet, however, had already gone south in November; and the surviving major ships and bomber aircraft, which were vulnerable for lack of fighter protection, were withdrawn in the next fortnight to safety in bases in Java and Australia.

Japanese forces began to land on the island of Luzon in the Philippines on December 10. The main assault, consisting of the bulk of one division, was made at Lingayen Gulf, 100 miles north-northwest of Manila, on December 22, and a second large landing took place south of Manila two days later. Manila itself fell unopposed to the Japanese on Jan. 2, 1942, but by that time the U.S. and Filipino forces under General Douglas MacArthur were ready to hold Bataan Peninsula (across the bay from Manila) and Corregidor Island (in the bay). The Japanese attack on Bataan was halted initially, but it was reinforced in the following eight weeks. MacArthur was ordered to Australia on March 11, leaving Bataan's defense to Lieutenant General Jonathan M. Wainwright. The latter and his men surrendered on April 9; Corregidor fell in the night of May 5–6; and the southern Philippines capitulated three days later.

Bataan and Corregidor defended and lost

Japanese bombers had already destroyed British air power at Hong Kong on Dec. 8, 1941, and the British and Canadian defenders surrendered to the ground attack from the Kowloon Peninsula (the nearest mainland) on December 25. To secure their flank while pushing southward into Malaya, the Japanese also occupied Bangkok on December 9 and Victoria Point in southernmost Burma on December 16. The Japanese landings in Malaya, from December 8 onward, accompanied as they were by air strikes, overwhelmed the small Australian and Indian forces; and the British battleship *Prince of Wales* and the battle cruiser *Repulse,* sailing from Singapore to cut Japanese communications, were sunk by Japanese aircraft on December 10. By the end of January 1942, two Japanese divisions, with air and armoured support, had occupied all Malaya except Singapore Island. In Burma, meanwhile, other Japanese troops had taken Moulmein and were approaching Rangoon and Mandalay.

On the eastern perimeter of the war zone, the Japanese had bombed Wake Island on December 8, attempted to capture it on December 11, and achieved a landing on December 23, quickly subduing the garrison. Guam had already fallen on December 10. Having also occupied Makin and Tarawa in the Gilbert Islands in the first days of the war, the Japanese successfully attacked Rabaul, the strategic base on New Britain (now part of Papua New Guinea), on Jan. 23, 1942.

A unified American–British–Dutch–Australian Command, ABDACOM, under Wavell, responsible for holding Malaya, Sumatra, Java, and the approaches to Australia, became operative on Jan. 15, 1942; but the Japanese had already begun their advance on the oil-rich Dutch East Indies. They occupied Kuching (December 17), Brunei Bay (January 6), and Jesselton (January 11), on the northern coast of Borneo, as well as Tarakan Island (off northeastern Borneo) and points on Celebes. Balikpapan (on Borneo's

east coast) and Kendari (in southeastern Celebes) fell to the Japanese on Jan. 24, 1942, Amboina on February 4, Makasar City (in southwestern Celebes) on February 8, and Bandjarmasin (in southern Borneo) on February 16. Bali was invaded on February 18, and by February 24 the Japanese were also in possession of Timor.

Meanwhile, on February 8 and 9, three Japanese divisions had landed on Singapore Island; and on February 15 they forced the 90,000-strong British, Australian, and Indian garrison there, under Lieutenant General A.E. Percival, to surrender. Singapore was the major British base in the Pacific and had been regarded as unassailable due to its strong seaward defenses. The Japanese took it with comparative ease by advancing down the Malay Peninsula and then assaulting the base's landward side, which the British had left inadequately defended. On February 13, moreover, Japanese paratroopers had landed at Palembang in Sumatra, which fell to an amphibious assault three days later.

The fall of Singapore

When ABDACOM was dissolved on Feb. 25, 1942, only Java remained to complete the Japanese program of conquest. The Allies' desperate attempt to intercept the Japanese invasion fleet was defeated in the seven-hour Battle of the Java Sea on February 27, in which five Allied warships were lost and only one Japanese destroyer damaged. The Japanese landed at three points on Java on February 28 and rapidly expanded their beachheads. On March 9 the 20,000 Allied troops in Java surrendered. In the Indian Ocean, the Japanese captured the Andaman Islands on March 23, and began a series of attacks on British shipping. After the failure of ABDACOM, the U.S.–British Combined Chiefs of Staff placed the Pacific under the U.S. Joint Chiefs' strategic direction. MacArthur became supreme commander of the Southwest Pacific Area, which comprised the Dutch East Indies (less Sumatra), the Philippines, Australia, the Bismarck Archipelago, and the Solomons; and Admiral Chester W. Nimitz became commander in chief of the Pacific Ocean Areas, which comprised virtually every area not under MacArthur. Their missions were to hold the U.S.–Australia line of communications, to contain the Japanese within the Pacific, to support the defense of North America, and to prepare for major amphibious counteroffensives.

Japan's initial war plans were realized with the capture of Java. But despite their military triumphs, the Japanese saw no indication that the Allies were ready for a negotiated peace. On the contrary, it seemed evident that an Allied counterstroke was in the making. The U.S. Pacific Fleet bombed the Marshall Islands on Feb. 1, 1942, Wake Island on February 23, and Marcus Island (between Wake and Japan) on March 1. These moves, together with the bombing of Rabaul on February 23 and the establishment of bases in Australia and a line of communications across the South Pacific, made the Japanese decide to expand so as to cut the Allied line of communications to Australia. They planned to occupy New Caledonia, the Fiji Islands, and Samoa and also to seize eastern New Guinea, whence they would threaten Australia from an air base to be established at Port Moresby. They planned also to capture Midway Island in the North Pacific and to establish air bases in the Aleutians. In pursuance of this new program, Japanese troops occupied Lae and Salamaua in New Guinea and Buka in the Solomon Islands in March 1942 and Bougainville in the Solomons and the Admiralty Islands (north of New Guinea) early in April.

Something to raise the Allies' morale was achieved on April 18, 1942, when 16 U.S. bombers raided Tokyo— though they did little real damage except to the Japanese government's prestige. Far more important were the consequences of the U.S. intelligence services' detection of Japanese plans to seize Port Moresby and Tulagi (in the southern Solomons). Had these two places fallen, Japanese aircraft could have dominated the Coral Sea. In the event, after U.S. aircraft on May 3, 1942, had interfered with the Japanese landing on Tulagi, U.S. naval units, with aircraft, challenged the Japanese ships on their circuitous detour from Rabaul to Port Moresby. On May 5 and 6 the opposing carrier groups sought each other out, and the four-day Battle of the Coral Sea ensued. On May 7 planes

The Battle of the Coral Sea

from the Japanese carriers sank a U.S. destroyer and an oil tanker, but U.S. planes sank the Japanese light carrier *Shoho* and a cruiser; and the next day, though Japanese aircraft sank the U.S. carrier *Lexington* and damaged the carrier *Yorktown*, the large Japanese carrier *Shokaku* had to retire crippled. Finally, the Japanese lost so many planes in the battle that their enterprise against Port Moresby had to be abandoned.

Despite the mixed results of the Battle of the Coral Sea, the Japanese continued with their plan to seize Midway Island. Seeking a naval showdown with the remaining ships of the U.S. Pacific Fleet and counting on their own numerical superiority to secure a victory, the Japanese mustered four heavy and three light aircraft carriers, two seaplane carriers, 11 battleships, 15 cruisers, 44 destroyers, 15 submarines, and miscellaneous small vessels. The U.S. Pacific Fleet had only three heavy carriers, eight cruisers, 18 destroyers, and 19 submarines, though there were some 115 aircraft in support of it. The Americans, however, had the incomparable advantage of knowing the intentions of the Japanese in advance, thanks to the U.S. intelligence services' having broken the Japanese Navy's code and deciphered key radio transmissions. In the ensuing Battle of Midway, the Japanese ships destined to take Midway Island were attacked while still 500 miles from their target by U.S. bombers on June 3. The Japanese carriers were still able to launch their aircraft against Midway early on June 4, but in the ensuing battle, waves of carrier- and Midway-based U.S. bombers sank all four of the Japanese heavy carriers and one heavy cruiser. Appalled by this disaster, the Japanese began to retreat in the night of June 4–5. Though the U.S. carrier *Yorktown* was sunk by torpedo on June 6, Midway was saved from invasion. In the Aleutians, the Japanese bombed Dutch Harbor effectively and on June 7 occupied Attu and Kiska.

The Battle of Midway was probably the turning point of the war in the Pacific, for Japan lost its first-line carrier strength and most of its navy's best trained pilots. Henceforth, the naval strengths of the Japanese and of the Allies were virtually equal. Having lost the strategic initiative, Japan canceled its plans to invade New Caledonia, Fiji, and Samoa.

The Chinese front and Burma, 1941–42. Japan's entry into war against the western Allies had its repercussions in China. Chiang Kai-shek's government on Dec. 9, 1941, formally declared war not only against Japan (a formality long overdue) but also, with political rather than military intent, against Germany and Italy. Three Chinese armies were rushed to the Burmese frontier, since the Burma Road was the only land route whereby the western Allies could send supplies to the Nationalist Chinese government. On Jan. 3, 1942, Chiang was recognized as supreme Allied commander for the China theatre of war; and a U.S. general, Joseph W. Stilwell, was sent to him to be his chief of staff. In the first eight weeks after Pearl Harbor, however, the major achievement of the Chinese was the definitive repulse, on Jan. 15, 1942, of a long-sustained Japanese drive against Ch'ang-sha, on the Canton–Hank'ou railway.

Thereafter, Chiang and Stilwell were largely preoccupied by efforts to check the Japanese advance into Burma. By mid-March 1942 two Chinese armies, under Stilwell's command, had crossed the Burmese frontier; but before the end of the month the Chinese force defending Toungoo, in central Burma between Rangoon and Mandalay, was nearly annihilated by the more soldierly Japanese. British and Indian units in Burma fared scarcely better, being driven into retreat by the enemy's numerical superiority both in the air and on the ground. On April 29 the Japanese took Lashio, the Burma Road's southern terminus, thus cutting the supply line to China and turning the Allies' northern flank. Under continued pressure, the British and Indian forces in the following month fell back through Kalewa to Imphāl (across the Indian border), while most of the Chinese retreated across the Salween River into China. By the end of 1942 all of Burma was in Japanese hands, China was effectively isolated (except by air), and India was exposed to the danger of a Japanese invasion through Burma.

The Battle of Midway

Stilwell as Chiang's chief of staff

Since the U.S. bombers that raided Tokyo on April 18 flew on to Chinese airfields, particularly to those in Chekiang (the coastal province south of Shanghai), the Japanese reacted by launching a powerful offensive to seize those airfields. By the end of July they had generally achieved their objectives.

DEVELOPMENTS FROM AUTUMN 1941 TO SPRING 1942

Allied strategy and controversies, 1940–42. In the year following the collapse of France in June 1940, British strategists, relying as they could on supplies from the nonbelligerent United States, were concerned first with home defense, second with the security of the British positions in the Middle East, and third with the development of a war of attrition against the Axis powers, pending the buildup of adequate forces for an invasion of the European continent. For the United States, President Roosevelt's advisers, from November 1940, based their strategic plans on the "Europe first" principle: that is to say, if the United States became engaged in war simultaneously against Germany, Italy, and Japan, merely defensive operations should be conducted in the Pacific (to protect at least the Alaska–Hawaii–Panama triangle) while an offensive was being mounted in Europe.

Japan's entry into the war terminated the nonbelligerency of the United States. The three weeks' conference, named Arcadia, that Roosevelt, Churchill, and their advisers opened in Washington, D.C., on Dec. 22, 1941, reassured the British about U.S. maintenance of the "Europe first" principle and also produced two plans: a tentative one, code-named "Sledgehammer," for the buildup of an offensive force in Great Britain, in case it should be decided to invade France; and another, code-named "Super-Gymnast," for combining a British landing behind the German forces in Libya (already planned under the code name "Gymnast") with a U.S. landing near Casablanca on the Atlantic coast of Morocco. The same conference furthermore created the machinery of the Combined Chiefs of Staff, where the British Chiefs of Staff Committee was to be linked continuously, through delegates in Washington, D.C., with the newly established U.S. Joint Chiefs of Staff Organization, so that all aspects of the war could be studied in concert. It was on Jan. 1, 1942, during the Arcadia Conference, that the Declaration of the United Nations was signed in Washington, D.C., as a collective statement of the Allies' war aims in sequel to the Atlantic Charter.

Meanwhile, Churchill became anxious to do something to help the embattled Soviets—who were clamouring for the United States and Britain to invade continental Europe so as to take some of the German pressure off the Eastern Front. Roosevelt was no less conscious than Churchill of the fact that the Soviet Union was bearing by far the greatest burden of the war against Germany; and this consideration inclined him to listen to the arguments of his Joint Chiefs of Staff Organization for a change of plan. After some hesitation, he sent his confidant Harry Hopkins and his army chief of staff General George C. Marshall to London in April 1942 to suggest the scrapping of "Super-Gymnast" in favour of "Bolero," namely the concentration of forces in Great Britain for a landing in Europe (perhaps at Brest or at Cherbourg) in the autumn; then "Roundup," an invasion of France by 30 U.S. and 18 British divisions, could follow in April 1943. The British agreed but soon began to doubt the practicability of mounting an amphibious invasion of France at such an early date.

Attempts to conclude an Anglo-Soviet political agreement were renewed without result, but a 20-year Anglo-Soviet alliance was signed on May 26, 1942; and, though Churchill warned Molotov not to expect an early second front in Europe, Molotov seemed gratified by what he was told about Anglo-U.S. plans.

Visiting Roosevelt again in the latter part of June 1942, Churchill at Hyde Park, N.Y., and in Washington, D.C., pressed for a revised and enlarged joint operation in North Africa before the end of the year, instead of a buildup for the invasion of France; but the U.S. Joint Chiefs resolutely upheld the latter plan. After further debate and disagreement, in July the U.S. Joint Chiefs yielded at

The Arcadia Conference

The Anglo-Soviet Alliance and the Hyde Park Conference

last to British obstinacy in favour of a North African enterprise: it was decided that "Torch," as this combined Anglo-U.S. operation came to be called, should begin the following autumn.

Already, on July 17, 1942, Churchill had had to notify Stalin that convoys of Allied supplies to northern Russia must be suspended because of German submarine activity on the Arctic sea route (on June 2 a convoy from Iceland had lost 23 out of 34 vessels). Consequently, it was the more awkward to inform Stalin that there would be no second front in Europe before 1943. In mid-August 1942, when Churchill went to Moscow to break the news, Stalin raged against the retreat from the plan for a second front in Europe but had to admit the military logic of "Torch."

Libya and Egypt, autumn 1941–summer 1942. In the Western Desert, a major offensive against Rommel's front was undertaken on Nov. 18, 1941, by the British 8th Army, commanded by Cunningham under the command in chief of Wavell's successor in the Middle East, General Sir Claude Auchinleck. The offensive was routed. General Neil Methuen Ritchie took Cunningham's place on November 25, still more tanks were brought up, and a fortnight's resumed pressure constrained Rommel to evacuate Cyrenaica and to retreat to Agedabia. There, however, Rommel was at last, albeit meagrely, reinforced; and, after repulsing a British attack on December 26, he prepared a counteroffensive. When the British still imagined his forces to be hopelessly crippled, he attacked on Jan. 21, 1942, and, by a series of strokes, drove the 8th Army back to the Gazala–Bir Hakeim line, just west of Tobruk.

Both sides were subsequently further reinforced. Then, on the night of May 26–27, Rommel passed around Ritchie's southern flank with his three German divisions and two Italian ones, leaving only four Italian divisions to face the Gazala line. Though at first Rommel did some damage to the British tanks as they came into action piecemeal from a weak position, he failed to break through to the coast behind Gazala. In a single day one-third of Rommel's tank force was lost; and, after another unsuccessful effort to reach the coast, he decided, on May 29, to take up a defensive position.

The
Cauldron

The new German position, aptly known as the Cauldron, seemed indeed to be perilously exposed; and throughout the first days of June the British attacked it continually from the air and from the ground, imagining that Rommel's armour was caught at last. The British tanks, however, persisted in making direct assaults in small groups against the Cauldron and were beaten off with very heavy losses; and Rommel, meanwhile, secured his rear and his line of supply by overwhelming several isolated British positions to the south.

Whereas in May 1942 the British had had 700 tanks, with 200 more in reserve, against Rommel's 525, by June 10 their present armoured strength was reduced, through their wasteful tactics against the Cauldron, to 170, and most of the reserve was exhausted. Suddenly then, on June 11, Rommel struck eastward, to catch most of the remaining British armour in the converging fire of two panzer divisions. By nightfall on June 13 the British had barely 70 tanks left, and Rommel, with some 150 still fit for action, was master of the battlefield.

The British on June 14 began a precipitate retreat from the Gazala line toward the Egyptian frontier. A garrison of 33,000 men, however, with an immense quantity of material, was left behind in Tobruk—on the retention of which Churchill characteristically and most unfortunately insisted in successive telegrams from London. Rommel's prompt reduction of Tobruk, achieved on June 21, 1942, was felt by Great Britain as a national disaster second only to the loss of Singapore; and 80 percent of the transport with which Rommel chased the remnant of the 8th Army eastward consisted of captured British vehicles.

At this point Auchinleck relieved Ritchie of his command and in a realistic and soldierly way ordered a general British retreat back to the Alamein area. By June 30 the German tanks were pressing against the British positions between el-Alamein (al-'Alamayn) and the Qattara Depression, some 60 miles west of Alexandria, after an advance of more than 350 miles from Gazala. Hitler

and Mussolini could expect that within a matter of days Rommel would be the master of Egypt.

The ensuing First Battle of el-Alamein, which lasted throughout July 1942, marked the end of the German hopes of a rapid victory. Rommel's troops, having come so far and so fast, were exhausted; their first assaults failed to break the defense rallied by Auchinleck; and they were also subjected to disconcerting counterstrokes. At this point, the respite that Rommel had to grant to his men gave Auchinleck time to bring up reinforcements. By the end of July Rommel knew that it was he rather than Auchinleck who was now on the defensive.

Rommel
halted

Auchinleck had saved Egypt by halting Rommel's invasion, but his counterattacks had not driven it back. Early in August, when Churchill arrived in Cairo to review the situation, Auchinleck insisted on postponing the resumption of the offensive until September, so that his new forces could be properly acclimatized and trained for desert warfare. Impatient of this delay, Churchill removed Auchinleck from the command in chief in the Middle East and gave the post to General Sir Harold Alexander, while the command of the 8th Army was transferred eventually (after the sudden death of Churchill's first nominee) to General Bernard Law Montgomery. Paradoxically, Montgomery postponed the resumption of the offensive even longer than Auchinleck had desired.

While the British in the course of August raised their strength in armour at the front to some 700 tanks, Rommel received only meagre reinforcement in the shape of infantry. He had, however, about 200 gun-armed German tanks and also 240 Italian tanks (of an obsolete model). With this armament, in the night of Aug. 30–31, 1942, he launched a fresh attack, intending to capture by surprise the minefields on the southern sector of the British front and then to drive eastward with his armour for some 30 miles before wheeling north into the 8th Army's supply area on the coast. In the event, the minefields proved unexpectedly deep, and by daybreak Rommel's spearhead was only eight miles beyond them. Delayed on their eastward drive and already under attack from the air, the two German panzer divisions of the Afrika Korps had to make their wheel to the north at a much shorter distance from the breach than Rommel had planned. Their assault thus ran mainly into the position held by the British 22nd Armoured Brigade, to the southwest of the ridge 'Alam al-Halfa'. Shortage of fuel on the German side and reinforced defense on the British, together with intensification of the British bombing, spelled the defeat of the offensive, and Rommel on September 2 decided to make a gradual withdrawal.

The Germans' summer offensive in southern Russia, 1942. The German plan to launch another great summer offensive crystallized in the early months of 1942. Hitler's decision was influenced by his economists, who mistakenly told him that Germany could not continue the war unless it obtained petroleum supplies from the Caucasus. Hitler was the more responsive to such arguments because they coincided with his belief that another German offensive would so drain the Soviet Union's manpower that the U.S.S.R. would be unable to continue the war. His thinking was shared by his generals, who had been awed by the prodigality with which the Soviets squandered their troops in the fighting of 1941 and the spring of 1942. By this time at least 4,000,000 Soviet troops had been killed, wounded, or captured, while German casualties totaled only 1,150,000.

In the early summer of 1942 the German southern line ran from Orël southward east of Kursk, through Belgorod, and east of Kharkov down to the loop of the Soviet salient opposite Izyum, beyond which it veered southeastward to Taganrog, on the northern coast of the Sea of Azov. Before the Germans were ready for their principal offensive, the Red Army in May started a drive against Kharkov; but this premature effort actually served the Germans' purposes, since it not only preempted the Soviet reserves but also provoked an immediate counterstroke against its southern flank, where the Germans broke into the salient and reached the Donets River near Izyum. The Germans captured 240,000 Soviet prisoners in the encirclement that

followed. In May also the Germans drove the Soviet defenders of the Kerch Peninsula out of the Crimea; and on June 3 the Germans began an assault against Sevastopol, which, however, held out for a month.

The Germans' crossing of the Donets near Izyum on June 10, 1942, was the prelude to their summer offensive, which was launched at last on June 28: Field Marshal Maximilian von Weichs's Army Group B, from the Kursk–Belgorod sector of the front, struck toward the middle Don River opposite Voronezh, whence General Friedrich Paulus' 6th Army was to wheel southeastward against Stalingrad (Volgograd); and List's Army Group A, from the front south of Kharkov, with Kleist's 1st Panzer Army, struck toward the lower Don to take Rostov and to thrust thence northeastward against Stalingrad as well as southward into the vast oil fields of Caucasia. Army Group B swept rapidly across a 100-mile stretch of plain to the Don and captured Voronezh on July 6. The 1st Panzer Army drove 250 miles from its starting line and captured Rostov on July 23. Once his forces had reached Rostov, Hitler decided to split his troops so that they could both invade the rest of the Caucasus and take the important industrial city of Stalingrad on the Volga River, 220 miles northeast of Rostov. This decision was to have fatal consequences for the Germans, since they lacked the resources to successfully take and hold both of these objectives.

The German thrust into Caucasia

Maikop (Maykup), the great oil centre 200 miles south of Rostov, fell to Kleist's right-hand column on August 9, and Pyatigorsk, 150 miles east of Maikop, fell to his centre on the same day, while the projected thrust against Stalingrad, in the opposite direction from Rostov, was being developed. Shortage of fuel, however, slowed the pace of Kleist's subsequent southeastward progress through the Caucasian mountains; and, after forcing a passage over the Terek River near Mozdok early in September, he was halted definitively just south of that river. From the end of October 1942 the Caucasian front was stabilized; but the titanic struggle for Stalingrad, draining manpower that might have won victory for the Germans in Caucasia, was to rage on, fatefully, for three more months (see below). Already, however, it was evident that Hitler's new offensive had fallen short of its objectives, and the scapegoat this time was Halder, who was superseded by Kurt Zeitzler as chief of the army general staff.

The Allies' first decisive successes

The Solomons, Papua, Madagascar, the Aleutians, and Burma, July 1942–May 1943. On July 2, 1942, the U.S. Joint Chiefs of Staff ordered limited offensives in three stages to recapture the New Britain–New Ireland–Solomons–eastern New Guinea area: first, the seizure of Tulagi and of the Santa Cruz Islands, with adjacent positions; second, the occupation of the central and northern Solomons and of the northeast coast of New Guinea; third, the seizure of Rabaul and of other points in the Bismarck Archipelago.

Guadal-canal

On July 6 the Japanese landed troops on Guadalcanal, one of the southern Solomons, and began to construct an air base. The Allied high command, fearing further Japanese advances southeastward, sped into the area to dislodge the enemy and to obtain a base for later advances toward Japan's main base in the theatre, Rabaul. The U.S. 1st Marine Division poured ashore on August 7 and secured Guadalcanal's airfield, Tulagi's harbour, and neighbouring islands by dusk on August 8—the Pacific war's first major Allied offensive. During the night of August 8–9, Japanese cruisers and destroyers, attempting to hold Guadalcanal, sank four U.S. cruisers, themselves sustaining one cruiser sunk and one damaged and later sunk. On August 23–25, in the Battle of the Eastern Solomons, the Japanese lost a light carrier, a destroyer, and a submarine and sustained damage to a cruiser and to a seaplane carrier but sank an Allied destroyer and crippled a cruiser. On August 31 another U.S. carrier was disabled, and on September 15 Japanese submarines sank the carrier *Wasp* and damaged a battleship. Meanwhile, more than 6,000 Japanese reinforced their Guadalcanal

garrison, attacking the Marines' beachhead on August 20–21 and on September 12–14. On September 18 some U.S. reinforcements arrived, and mid-October saw about 22,-000 Japanese ranged against 23,000 U.S. troops. The sea battles of Cape Esperance and of the Santa Cruz Islands—in which two Japanese cruisers and two destroyers were sunk and three carriers and two destroyers damaged in return for the loss of one U.S. carrier and two destroyers, besides damage to six other Allied ships—thwarted an attempt to reinforce further the Japanese ground troops, whose attack proved a failure (October 20–29).

After October, Allied strength was built up. Another Japanese attempt at counter-reinforcement led to the naval Battle of Guadalcanal, fought on November 13–15: it cost Japan two battleships, three destroyers, one cruiser, two submarines, and 11 transports and the Allies (now under Admiral William F. Halsey) two cruisers and seven destroyers sunk and one battleship and one cruiser damaged. Only 4,000 Japanese troops out of 12,500 managed to reach land, without equipment; and on November 30 eight Japanese destroyers, attempting to land more troops, were beaten off in the Battle of Tassafaronga, losing one destroyer sunk and one crippled, at an Allied cost of one cruiser sunk and three damaged.

By Jan. 5, 1943, Guadalcanal's Allied garrison totaled 44,000, against 22,500 Japanese. The Japanese decided to evacuate the position, carrying away 12,000 men in early February in daring destroyer runs. In ground warfare Japanese losses were more than 24,000 for the Guadalcanal campaign, Allied losses about 1,600 killed and 4,250 wounded (figures that ignore the higher number of casualties from disease). On February 21, U.S. infantry began occupying the Russell Islands, to support advances on Rabaul.

Earlier, before Allied plans to secure eastern New Guinea had been implemented, the Japanese had landed near Gona on the north coast of Papua (the southeastern extremity of the great island) on July 24, 1942, in an attempt to reach Port Moresby overland, via the Kokoda Trail. Advanced Japanese units from the north, despite Australian opposition, had reached a ridge 32 miles from Port Moresby by mid-September. Then, however, they had to withdraw exhausted to Gona and to nearby Buna, where there were some 7,500 Japanese assembled by November 18. The next day U.S. infantry attacked them there. Each side was subsequently reinforced; but the Australians took Gona on December 9 and the Americans Buna village on December 14. Buna government station fell to the Allies on Jan. 2, 1943, Sanananda on January 18, and all Japanese resistance in Papua ceased on January 22.

The defense of Port Moresby

The retaking of Guadalcanal and Papua ended the Japanese drive south, and communications with Australia and New Zealand were now secure. Altogether, Papua cost Japan nearly 12,000 killed and 350 captured. Allied losses were 3,300 killed and 5,500 wounded. Allied air forces had played a particularly important role, interdicting Japanese supply lines and transporting Allied supplies and reinforcements.

Japan, having lost Guadalcanal, fought henceforth defensively, with worsening prospects. Its final effort to reinforce the Lae–Salamaua position in New Guinea from the stronghold of Rabaul was a disaster: in the Battle of the Bismarck Sea, on March 2–4, 1943, the Japanese lost four destroyers and eight transports, and only 1,000 of the 7,000 troops reached their destination. On March 25 the Japanese Army and Navy high commands agreed on a policy of strengthening the defense of strategic points and of counterattacking wherever possible, priority being given to the defense of the remaining Japanese positions in New Guinea, with secondary emphasis on the Solomon Islands. In the following three weeks, however, the Allies improved their own position in New Guinea, and Japanese intervention was confined to air attacks. Before the end of April, moreover, the Japanese Navy sustained a disaster: the guiding genius of the Japanese war effort, Yamamoto, was sent late in March to command the forces based on Rabaul but was killed in an American air ambush on a flight to Bougainville.

The Battle of the Bismarck Sea

Developments of the Allies' war against Japan also took

place outside the southwest Pacific area. British forces in the summer of 1942 invaded Vichy French-held Madagascar. A renewed British offensive in September 1942 overran the island; hostilities ceased on November 5, and a Free French administration of Madagascar took office on Jan. 8, 1943. In the North Pacific, meanwhile, the United States had decided to expel the Japanese from the Aleutians. Having landed forces on Adak in August 1942, they began air attacks against Kiska and Attu from Adak the next month and from Amchitka also in the following January, while a naval blockade prevented the Japanese from reinforcing their garrisons. Finally, U.S. troops, bypassing Kiska, invaded Attu on May 11, 1943—to kill most of the island's 2,300 defenders in three weeks of fighting. The Japanese then evacuated Kiska. Bases in the Aleutians thenceforth facilitated the Allies' bombing of the Kuril Islands.

Burma, autumn 1942–summer 1943. On the Burmese front the Allies found they could do little to dislodge the Japanese from their occupation of that country, and what little the Allies did attempt proved abortive. Brigadier General Orde Wingate's "Chindits," which were long-range penetration groups depending on supplies from the air, crossed the Chindwin River in February 1943 and were initially successful in severing Japanese communications on the railroad between Mandalay and Myitkyina. But the Chindits soon found themselves in unfavourable terrain and in grave danger of encirclement, and so they made their way back to India.

In May 1943, however, the Allies reorganized their system of command for Southeast Asia. Vice Admiral Lord Louis Mountbatten was appointed supreme commander of the South East Asia Command (SEAC), and Stilwell was appointed deputy to Mountbatten. Stilwell at the same time was chief of staff to Chiang Kai-shek. The British–Indian forces destined for Burma meanwhile constituted the 14th Army, under Lieutenant General William Slim, whose operational control Stilwell agreed to accept. Shortly afterward, Auchinleck succeeded Wavell as commander in chief in India.

Montgomery's Battle of el-Alamein and Rommel's retreat, 1942–43. While Churchill was still chafing in London about his generals' delay in resuming the offensive in Egypt, Montgomery waited for seven weeks after 'Alam al-Halfa' in order to be sure of success. He finally chose to begin his attack in the night of Oct. 23–24, 1942, when there would be moonlight for the clearing of gaps in the German minefields.

By mid-October the British 8th Army had 230,000 men and 1,230 gun-armed tanks ready for action, while the German–Italian forces numbered only 80,000 men, with only 210 tanks of comparable quality ready; and in air support the British enjoyed a superiority of 1,500 to 350. Allied air and submarine attacks on the Axis supply lines across the Mediterranean, moreover, had prevented Rommel's army from receiving adequate replenishments of fuel, ammunition, and food; and Rommel himself, who had been ill before 'Alam al-Halfa', was convalescing in Austria.

The British launched their infantry attack at el-Alamein at 10:00 PM on Oct. 23, 1942, but found the German minefields harder to clear than they had foreseen. Two days later, however, some of those tanks were deploying six miles beyond the original front. When Rommel, ordered back to Africa by Hitler, reached the front in the evening of October 25, half of the Germans' available armour was already destroyed. Nevertheless, the impetus of the British onslaught was stopped the next day, when German antitank guns took a heavy toll of armour trying to deepen the westward penetration. In the night of October 28 Montgomery turned the offensive northward from the wedge, but this drive likewise miscarried. In the first week of their offensive the British lost four times as many tanks as the Germans but still had 800 available against the latter's remaining 90.

When Montgomery switched the British line of attack back to its original direction, early on Nov. 2, 1942, Rommel was no longer strong enough to withstand him. After expensive resistance throughout the daytime, he ordered a

retreat to Fūka (Fūkah); but in the afternoon of November 3 the retreat was fatally countermanded by Hitler, who insisted that the Alamein position be held. The 36 hours wasted in obeying this long-distance instruction cost Rommel his chance of making a stand at Fūka: when he resumed his retreat, he had to race much farther back to escape successive British attempts to intercept him on the coast road by scythelike sweeps from the south. A fortnight after resuming his withdrawal from el-Alamein, Rommel was 700 miles to the west, at the traditional backstop of Agheila. As the British took their time to mount their attacks, he fell back farther by stages: after three weeks, 200 miles to Buerat (al-Bu'ayrāt); after three more weeks, in mid-January 1943, the whole distance of 350 miles past Tripoli to the Mareth Line within the frontiers of Tunisia. By that time the Axis position in Tunisia was being battered from the west, through the execution of "Torch."

Stalingrad and the German retreat, summer 1942–February 1943. The German 4th Panzer Army, after being diverted to the south to help Kleist's attack on Rostov late in July 1942 (see above), was redirected toward Stalingrad a fortnight later. Stalingrad was a large industrial city producing armaments and tractors; it stretched for 30 miles along the banks of the Volga River. By the end of August the 4th Army's northeastward advance against the city was converging with the eastward advance of the 6th Army, under General Friedrich Paulus, with 330,000 of the German Army's finest troops. The Red Army, however, put up the most determined resistance, yielding ground only very slowly and at a high cost as the 6th Army approached Stalingrad. On August 23 a German spearhead penetrated the city's northern suburbs, and the Luftwaffe rained incendiary bombs that destroyed most of the city's wooden housing. The Soviet 62nd Army was pushed back into Stalingrad proper, where, under the command of General Vasily I. Chuikov, it made a determined stand. Meanwhile, the Germans' concentration on Stalingrad was increasingly draining reserves from their flank cover, which was already strained by having to stretch so far—400 miles on the left (north), as far as Voronezh, 400 again on the right (south), as far as the Terek River. By mid-September the Germans had pushed the Soviet forces in Stalingrad back until the latter occupied only a nine-mile-long strip of the city along the Volga, and this strip was only two or three miles wide. The Soviets had to supply their troops by barge and boat across the Volga from the other bank. At this point Stalingrad became the scene of some of the fiercest and most concentrated fighting of the war; streets, blocks, and individual buildings were fought over by many small units of troops and often changed hands again and again. The city's remaining buildings were pounded into rubble by the unrelenting close combat. The most critical moment came on October 14, when the Soviet defenders had their backs so close to the Volga that the few remaining supply crossings of the river came under German machine-gun fire. The Germans, however, were growing dispirited by heavy losses, by fatigue, and by the approach of winter.

A huge Soviet counteroffensive, planned by generals G.K. Zhukov, A.M. Vasilevsky, and Nikolay Nikolayevich Voronov, was launched on Nov. 19–20, 1942, in two spearheads, north and south of the German salient whose tip was at Stalingrad. The twin pincers of this counteroffensive struck the flanks of the German salient at points about 50 miles north and 50 miles south of Stalingrad and were designed to isolate the 250,000 remaining men of the German 6th and 4th armies in the city. The attacks quickly penetrated deep into the flanks, and by November 23 the two prongs of the attack had linked up about 60 miles west of Stalingrad; the encirclement of the two German armies in Stalingrad was complete. The German high command urged Hitler to allow Paulus and his forces to break out of the encirclement and rejoin the main German forces west of the city, but Hitler would not contemplate a retreat from the Volga River and ordered Paulus to "stand and fight." With winter setting in and food and medical supplies dwindling, Paulus' forces grew weaker. In mid-December Hitler allowed one of the most talented German commanders, Field Marshal Erich von

Attu and Kiska *(margin)*

Strengths of the rival forces in North Africa *(margin)*

Rommel on the Mareth Line *(margin)*

Manstein, to form a special army corps to rescue Paulus' forces by fighting its way eastward, but Hitler refused to let Paulus fight his way westward at the same time in order to link up with Manstein. This fatal decision doomed Paulus' forces, since the main German forces now simply lacked the reserves needed to break through the Soviet encirclement singlehandedly. Hitler exhorted the trapped German forces to fight to the death, but on Jan. 31, 1943, Paulus surrendered; 91,000 frozen, starving men (all that was left of the 6th and 4th armies) and 24 generals surrendered with him.

Besides being the greatest battle of the war, Stalingrad proved to be the turning point of the military struggle between Germany and the Soviet Union. The battle used up precious German reserves, destroyed two entire armies, and humiliated the prestigious German war machine. It also marked the increasing skill and professionalism of a group of younger Soviet generals who had emerged as capable commanders, chief among whom was Zhukov.

Meanwhile, early in January 1943, only just in time, Hitler acknowledged that the encirclement of the Germans in Stalingrad would lead to an even worse disaster unless he extricated his forces from the Caucasus. Kleist was therefore ordered to retreat, while his northern flank of 600 miles was still protected by the desperate resistance of the encircled Paulus. Kleist's forces were making their way back across the Don at Rostov when Paulus at last surrendered. Had Paulus surrendered three weeks earlier (after seven weeks of isolation), Kleist's escape would have been impossible.

Even west of Rostov there were threats to Kleist's line of retreat. In January, two Soviet armies, the one under General Nikolay Fyodorovich Vatutin, the other under General Filipp Ivanovich Golikov, had crossed the Don upstream from Serafimovich and were thrusting southwestward to the Donets between Kamensk and Kharkov: Vatutin's forces, having crossed the Donets at Izyum, took Lozovaya Junction on February 11, Golikov's took Kharkov five days later. Farther to the north, a third Soviet army, under General Ivan Danilovich Chernyakhovsky, had initiated a drive westward from Voronezh on February 2 and had retaken Kursk on February 8. Thus, the Germans had to retreat from all the territory they had taken in their great summer offensive in 1942. The Caucasus returned to Soviet hands.

A sudden thaw supervened to hamper the Red Army's transport of supplies and reinforcements across the swollen courses of the great rivers. With the momentum of the Soviet counteroffensive thus slowed, the Germans made good their retreat to the Dnepr along the easier routes of the Black Sea littoral and were able, before the end of February 1943, to mount a counteroffensive of their own.

The invasion of northwest Africa, November–December 1942. When the U.S. and British strategists had decided on "Torch" (Allied landings on the western coast of North Africa) late in July 1942, it remained to settle the practical details of the operation. The purpose of "Torch" was to hem Rommel's forces in between U.S. troops on the west and British troops to the east. After considerable discussion, it was finally agreed that landings, under the supreme command of Major General Dwight D. Eisenhower, should be made on November 8 at three places in the vicinity of Casablanca on the Atlantic coast of Morocco and on beaches near Oran and near Algiers itself on the Mediterranean coast of Algeria. The amphibious landings would involve a total of about 110,000 troops, most of them Americans.

The conciliation of the French on whose colonial territory the landings would be made was a more delicate matter. All of French North Africa was still loyal to the Vichy government of Marshal Pétain, with which the United States, unlike Great Britain, was still formally maintaining diplomatic relations. Thus, the French commander in chief in Algeria, General Alphonse Juin, and his counterpart in Morocco, General Charles-Auguste Noguès, were subordinate to the supreme commander of all Vichy's forces, namely Admiral Jean-François Darlan. American diplomats and generals tried to gain these officers' collaboration with the Allies in the landings, for it was vital to

try to avoid a situation in which Vichy French troops put up armed resistance to the landings at the beaches.

The U.S.-British landings at Algiers began on November 8 and were met by little French resistance. The simultaneous landings near Oran met stiffer resistance, and on November 9 the whole U.S. plan of operations was dislocated by a French counterattack on the Arzew beachhead. Around Casablanca the U.S. landings were accomplished without difficulty, but resistance developed when the invaders tried to expand their beachheads. On November 10, however, the fighting was called off; and next day the French authorities in Morocco concluded an armistice with the Americans.

The landing in Algiers, meanwhile, was complicated by the fact that Darlan himself was in the city at the time. The situation was muddled, with some French troops loyal to Pétain while others backed de Gaulle and the anti-Vichy French general whom the Allies were sponsoring in North Africa, Henri Giraud.

On Nov. 11, 1942, in reaction to the Allied landings, German and Italian forces overran southern France, the metropolitan territory hitherto under Pétain's immediate authority. This event helped induce Noguès and the other French commanders in Algeria to assent to Darlan's proposals for a working agreement with the Allies, including recognition of Giraud as military commander in chief of the French forces. Concluded on November 13, the agreement was promptly endorsed by Eisenhower. French West Africa, including Senegal, with the port of Dakar, likewise followed Darlan's lead. The Germans, however, by mining the exit from the harbour of Toulon, forestalled plans for the escape of the main French fleet from metropolitan France to North Africa: on November 27, the French crews scuttled their ships to avoid capture. On Dec. 24, 1942, Darlan was assassinated; both Royalist and Gaullist circles in North Africa had steadfastly objected to him on political grounds. Giraud thereupon took his place, for a time, as French high commissioner in North Africa.

Tunisia, November 1942–May 1943. Axis troops had begun to arrive in Tunisia as early as Nov. 9, 1942, and were reinforced in the following fortnight until they numbered about 20,000 combat troops (which were subsequently heavily reinforced by air). Thus, when the British general Kenneth Anderson, designated to command the invasion of Tunisia from the west with the Allied 1st Army, started his offensive on November 25, the defense was unexpectedly strong. By December 5 the 1st Army's advance was checked a dozen miles from Tunis and from Bizerte. Further reinforcements enabled Colonel General Jürgen von Arnim, who assumed the command in chief of the Axis defense in Tunisia on December 9, to expand his two bridgeheads in Tunisia until they were merged into one. Germany and Italy had won the race for Tunis but were henceforth to succumb to the lure of retaining their prize regardless of the greater need of conserving their strength for the defense of Europe.

After Rommel had fallen back from Libya to the Mareth Line in mid-January 1943 (see above), two German armies, Arnim's and Rommel's, were holding the north and the south of the eastern littoral both against Anderson's 1st Army attacking from the west and against Montgomery's 8th from the southeast. Rommel judged that a counterstroke should be delivered first against the Allies in the west. Accordingly, on February 14 the Axis forces delivered a major attack against U.S. forces between the Fā'iḍ Pass in the north and Gafsa in the south. West of Fā'iḍ, the 21st Panzer Division, under General Heinz Ziegler, destroyed 100 U.S. tanks and drove the Americans back 50 miles. In the Kasserine Pass, however, the Allies put up some stiffer opposition.

When on February 19 Rommel received authority to continue his attack, he was ordered to advance not against Tébessa but northward from Kasserine against Thala— where, in fact, Alexander was expecting him. Having overcome the stubborn U.S. resistance in the Kasserine Pass on February 20, the Germans entered Thala the next day, only to be expelled a few hours later by Alexander's reserve troops. His chance having been forfeited, Rommel began a gradual withdrawal on February 22.

The delays ensuing from the frustration of Rommel's stroke against the 1st Army reduced the effectiveness of his stroke against the 8th. Whereas on Feb. 26, 1943, Montgomery had had only one division facing the Mareth Line, he quadrupled his strength in the following week, massing 400 tanks and 500 antitank guns. Rommel's attack, on March 6, was brought to an early halt, and 50 German tanks were lost. A sick man and a disappointed soldier, Rommel relinquished his command.

The Allied 1st Army resumed the offensive on March 17, with attacks by the U.S. II Corps, under General George Patton, on the roads through the mountains, with the aim of cutting the Afrika Korps' line of retreat up the coast to Tunis; but these attacks were checked by the Germans in the passes. In the night of March 20–21, however, the British 8th Army launched a frontal assault on the Mareth Line, combined with an outflanking movement by the New Zealand Corps toward el-Hamma (al-Ḥāmmah) in the Germans' rear; and a few days later, seeing the frontal assault to have failed, Montgomery switched the main weight of his attack to the flank. Threatened with encirclement, the Germans decided to abandon the Mareth Line, which the 8th Army occupied on March 28; but the German defenses at el-Hamma held out long enough to enable the rest of the Afrika Korps to retreat without much loss to a new line on the Wādī al-'Akārit, north of Gabès. The new line, however, was breached by the 8th Army on April 6; and, meanwhile, the Americans were also advancing on the Axis troops' rear from Gafsa. By the following morning the Afrika Korps was retreating rapidly northward along the littoral toward Tunis, and by April 11 it had joined hands with Arnim's forces for the defense of a 100-mile perimeter stretching around Tunis and Bizerte (Banzart).

Thanks to the rapidity of the Afrika Korps' retreat from Wādī al-'Akārit, the German high command had an opportunity to withdraw its forces from the rump of Tunisia to Sicily, but it chose instead to defend the indefensible rump. The defenders indeed withstood the converging assaults that the 8th and 1st armies delivered against the perimeter from April 20 to April 23; but on May 6 a concentrated attack by Allied artillery, aircraft, infantry, and tanks was launched on the two-mile front of the Medjerda (Majardah) Valley leading to Tunis; and on May 7 the city fell to the leading British armoured forces, while the Americans and the French almost simultaneously captured Bizerte. At the same time, the Germans' line of retreat into the Cap Bon Peninsula was severed by an armoured division's swift turn southeastward from Tunis. A general collapse of the German resistance followed, the Allies taking more than 250,000 prisoners, including 125,000 German troops and Arnim himself. North Africa had been cleared of Axis forces and was now completely in Allied hands. Its capture insured the safety of Allied shipping and naval movements throughout the Mediterranean, and North Africa would serve as a base for future Allied operations against Italy itself.

The **Atlantic, the Mediterranean, and the North Sea, 1942–45.** The year 1942 was, on the whole, a favourable one for the German U-boats. First, the U.S. entry into the war entitled them to infest the U.S. coast of the North Atlantic; and it was not until the middle of the year that the Allies' introduction of the convoy system from the Caribbean northward constrained the raiders to go so far afield as the waters between Brazil and West Africa. Second, U-tankers were developed; *i.e.*, large converted U-boats equipped to provide fuel, torpedoes, and other supplies to U-boats operating in remote waters. In the course of 1942, the U-boats sank more than 6,266,000 tons of shipping; and, since in the same period their operational strength rose from 91 to 212, it seemed conceivable that they might soon score their desired target of 800,000 tons of sinkings per month.

March 1943 saw the climax of the U-boats' good fortune: their strength rose to 240; they sank in that single month 627,377 tons of shipping; and, in the greatest convoy battle of the war, when 20 of them attacked two convoys merged into one, they sank 21 ships (141,000 tons) out of 77 with the loss of only one of their own number.

The anticlimax followed, thanks to five developments of the Allies' counteraction: "support groups" were reintroduced; aircraft carriers became progressively available for escorts; more and more long-range Liberator aircraft began to cover the convoys offshore; ships were equipped with a radar set of very short wavelength, the probing of which was undetectable to the U-boats; and a regular offensive against U-boats on their transit routes was launched from the air (56 were destroyed in April–May 1943). The U-boats sank 327,943 tons in April, 264,852 in May, only 95,753 in June 1943; and for the rest of the war monthly totals were less than 100,000 tons except in July and September 1943 and in March 1944.

Late in 1944 the U-boats were equipped with the snorkel breathing tube, which provided them with the necessary oxygen to recharge their batteries under water and so converted them from submersible torpedo boats into almost complete submarines virtually undetectable to radar. About the same time a new model of U-boat, with greater underwater speed and endurance, came into operation. These improvements came too late, however, because the Allies' surface and air resources for the protection of the convoys were already overwhelming.

Air warfare, 1942–43. Early in 1942 the RAF bomber command, headed by Sir Arthur Harris, began an intensification of the Allies' growing strategic air offensive against Germany. These attacks, which were aimed against factories, rail depots, dockyards, bridges, and dams and against cities and towns themselves, were intended to both destroy Germany's war industries and to deprive its civilian population of their housing, thus sapping their will to continue the war. The characteristic feature of the new program was its emphasis on area bombing, in which the centres of towns would be the points of aim for nocturnal raids.

Already in March 1942 an exceptionally destructive bombing raid, using the Germans' own incendiary method, had been made on Lübeck; and intensive attacks were also made on Essen (site of the Krupp munitions works) and other Ruhr towns. In the night of May 30–31 more than 1,000 bombers were dispatched against Cologne, where they did heavy damage to one-third of that city's built-up area. Such operations, however, became highly expensive to the bomber command, particularly because of the defense put up by the German night fighter force. Interrupted for two months during which the bombers concentrated their attention on U-boat bases on the Bay of Biscay, the air offensive against Germany was resumed in March 1943. In the following 12 months, moreover, its resources were to be increased formidably, so that by March 1944 the bomber command's average daily operational strength had risen to 974 from about 500 in 1942. These numbers helped the RAF to concentrate effectively against major industrial targets, such as those in the Ruhr. The phases of the resumed offensive were: (1) the Battle of the Ruhr, from March to July 1943, comprising 18,506 sorties and costing 872 aircraft shot down and 2,126 damaged, its most memorable operation being that of the night of May 16–17, when the Möhne Dam in the Ruhr Basin and the Eder Dam in the Weser Basin were breached, (2) the Battle of Hamburg, from July to November 1943, comprising 17,021 sorties and costing 695 bombers lost and 1,123 damaged but, nevertheless, thanks in part to the new Window antiradar and "H₂S" radar devices, achieving an unprecedented measure of devastation, since four out of its 33 major actions, with a little help from minor attacks, killed about 40,000 people and drove nearly 1,000,000 from their homes, and (3) the Battle of Berlin, from November 1943 to March 1944, comprising 20,224 sorties but costing 1,047 bombers lost and 1,682 returned damaged and achieving, on the whole, less devastation than the Battle of Hamburg.

The U.S. 8th Air Force, based in Great Britain, also took part in the strategic offensive against Germany from January 1943. Its bombers, Flying Fortresses and Liberators, attacked industrial targets in daylight. They proved, however, to be very vulnerable to German fighter attack whenever they went beyond the range of their own escort of fighters—that is to say, farther than the distance from Norfolk to Aachen: the raid against the important ball-

bearing factory at Schweinfurt, for instance, on Oct. 14, 1943, lost 60 out of the 291 bombers participating, and 138 of those that returned were damaged. Not until December 1943 was the P-51B (Mustang III) brought into operation with the 8th Air Force—a long-range fighter that portended a change in the balance of air power. The Germans, meanwhile, continued to increase their production of aircraft and, in particular, of their highly successful fighters.

German-occupied Europe. Hitler's racist ideology and his brutal conception of power politics caused him to pursue certain aims in those European countries conquered by the Germans in the period 1939–42. Hitler intended that those western and northern European areas in which civil administrations were installed—The Netherlands and Norway—would at some later date become part of the German Reich, or nation. Those countries left by Germany under military administration (which originally had been imposed everywhere), such as France and Serbia, would eventually be included more loosely in a German-dominated European bloc. Poland and the Soviet Union, on the other hand, were to be a colonial area for German settlement and economic exploitation.

Without regard to these distinctions, the SS, the elite corps of the Nazi Party, possessed exceptional powers throughout German-dominated Europe and in the course of time came to perform more and more executive functions, even in those countries under military administration. Similarly, the powers that Hitler gave to his chief labour commissioner, Fritz Sauckel, for the compulsory enrollment of foreign workers into the German armaments industry were soon applied to the whole of German-dominated Europe and ultimately turned 7,500,000 people into forced or slave labourers. Above all, however, there was the Final Solution of the "Jewish question" as ordered by Hitler, which meant the physical extermination of the Jewish people throughout Europe wherever German rule was in force or where German influence was decisive.

The Final Solution—that is to say the step beyond half-measures such as the concentration of Poland's Jews into overcrowded ghettoes—was introduced concurrently with Germany's preparations for the military campaign against the Soviet Union, since Hitler believed that the annihilation of the Communists entailed not only the extermination of the Soviet ruling class but also what he believed to be its "biological basis"—the millions of Jews in western Russia and the Ukraine. Accordingly, with the start of the invasion of the Soviet Union in 1941, special mobile killing squads began systematically shooting the Jewish population on conquered Soviet territory in the rear of the advancing German armies; in a few months, up to the end of 1941, they had killed about 1,400,000 people. Meanwhile, plans were made in 1941 to similarly exterminate the Jews of central and western Europe. At the Wannsee Conference of Nazi and SS chiefs in January 1942, it was agreed that those Jews would be deported and sent to camps in eastern Poland where they would be killed en masse or made to work as slave labourers until they perished. In the period from May 1942 to September 1944 more than 4,200,000 Jews were killed in such death camps as Auschwitz (Oświęcim), Treblinka, Belzec, Chełmno, Majdanek, and Sobibor. About 5,700,000 Jews died in the course of the Final Solution.

While Hitler destined the Jews in his empire to physical extermination, he regarded the Slavs, principally the Poles and the Russians, as "subhumans" who were to be subjected to continual decimation and used as a pool of cheap labour, that is to say, reduced to slavery. Poland became the training ground for this purpose. Upon the German conquest of Poland in 1939, Hitler ordered the SS to kill a large proportion of the Polish intelligentsia. A reign of terror against the nationalistic-minded Polish ruling classes began, and by the war's end a total of 3,000,000 Poles (in addition to 3,000,000 Polish Jews) had been killed. Hitler further willed that the whole mass of Slavs and Balts in the occupied portions of the Soviet Union should be indiscriminately subjected to German domination and should be economically exploited without hindrance or compassion. In the event, the Ukraine was

the major area subject to economic exploitation and also became the main source of slave labour. When the German armies first entered the Ukraine in July 1941, many Ukrainians had welcomed the Germans as their liberators from Stalinist terror and collectivization. But this goodwill soon turned to resentment as the Germans requisitioned large quantities of grain from the farms, forcibly deported several million Ukrainians for work in Germany, and engaged in brutal reprisals against civilians for acts of resistance or sabotage.

These inhumane occupation policies were practiced to a greater or lesser extent in all the countries occupied by the Germans, and the result was the beginning in 1940–41 of armed, underground resistance movements in those countries. Underground resistance was especially effective in the Soviet Union because it functioned behind fronts on which the German armies were still engaged in battle with the Red Army. The Soviet Partisans, as they were called, could thus covertly receive arms, equipment, and direction from the Soviet forces at the front itself. Soviet Partisans, like the members of other nations' Resistance movements, harassed and disrupted German military and economic activities by blowing up ammunition dumps and communications and transport facilities, sabotaging factories, ambushing small German units, and gathering military intelligence for use by the Allied armies. By 1944 the Resistance organizations in the Soviet Union, Poland, Yugoslavia, France, and Greece had grown quite large and were holding down many German divisions that were badly needed at the battlefront. In eastern Europe and Yugoslavia, the Resistance came to control large tracts of land in more inaccessible areas such as forests, mountain ranges, and swamplands. Some Resistance organizations, such as the Partisans in Yugoslavia and the National Liberation Movement in Greece, were Communist ones, while others, such as the Maquis in France and the Home Army in Poland, comprised people of many different political persuasions, though they were invariably anti-Fascists.

The German occupation authorities' attempts to eradicate the Resistance in most cases merely fanned the flames, due to the Germans' use of indiscriminate reprisals against civilians. It is generally agreed that by 1944 the Germans had earned the overwhelming antipathy of most of the people in the occupied nations of Europe. It should be noted, however, that the German occupation was in general far harsher in eastern Europe and the Balkans than in western Europe. In the Soviet Union, Poland, Yugoslavia, and Greece, a process of Resistance guerrilla warfare and Nazi reprisals began in 1941 and rose to a crescendo in 1943–44 as the fury of Nazi racism resulted in a war of annihilation upon the Slavic peoples.

Casablanca and Trident, January–May 1943. To decide what should be done after victory in North Africa, Roosevelt and Churchill, with their advisers, met at Casablanca in mid-January 1943. After long argument, it was eventually agreed that Sicily should be the next Axis area to be taken, in July. For the war against Japan, it was decided that two offensive operations should be undertaken: MacArthur should move toward the Japanese base at Rabaul, on the island of New Britain; and convergent movements on Burma should be made by the British from the mainland of India and by the Americans from the sea. Politically, the Casablanca Conference owes its importance to the fact that, at its end, Roosevelt publicly announced a demand for the unconditional surrender of Germany, Italy, and Japan.

Only four months after Casablanca it became necessary to hold another Anglo-U.S. conference. In mid-May 1943, Roosevelt, Churchill, and their advisers met, in Washington, D.C., for the conference code-named Trident. There the Sicilian project was effectively confirmed, and the date May 1, 1944, was prescribed—definitively in the U.S view, provisionally in the British—for the landing of 29 divisions in France; but the question whether the conquest of Sicily should be followed, as the British proposed, by an invasion of Italy was left unsettled.

The Eastern Front, February–September 1943. The German counteroffensive of February 1943 threw back the Soviet forces that had been advancing toward the Dnepr

River on the Izyum sector of the front, and by mid-March the Germans had retaken Kharkov and Belgorod and reestablished a front on the Donets River. Hitler also authorized the German forces to fall back, in March, from their advanced positions facing Moscow to a straighter line in front of Smolensk and Orël. Finally, there was the existence of the large Soviet bulge, or salient, around Kursk, between Orël and Belgorod, which extended for about 150 miles from north to south and protruded 100 miles into the German lines. This salient irresistibly tempted Hitler and Zeitzler into undertaking a new and extremely ambitious offensive instead of remaining content to hold their newly shortened front.

Hitler concentrated all efforts on this offensive without regard to the risk that an unsuccessful attack would leave him without reserves to maintain any subsequent defense of his long front. The Germans' increasing difficulty in building up their forces with fresh drafts of men and equipment was reflected in the increased delay that year in opening the summer offensive. Three months' pause followed the close of the winter campaign.

By contrast, the Red Army had improved much since 1942, both in quality and in quantity. The flow of new equipment had greatly increased, as had the number of new divisions, and its numerical superiority over the Germans was now about 4 to 1. Better still, its leadership had improved with experience: generals and junior commanders alike had become more skilled tacticians. That could already be discerned in the summer of 1943, when the Soviets waited to let the Germans lead off and commit themselves deeply to an offensive, and so stood well-poised to exploit the Germans' loss of balance in lunging.

The German offensive against the Kursk salient was launched on July 5, 1943, and into it Hitler threw 20 infantry divisions and 17 armoured divisions having a total of about 3,000 tanks. But the German tank columns got entangled in the deep minefields that the Soviets had laid, forewarned by the long preparation of the offensive. The Germans advanced only 10–30 miles, and no large bag of Soviet prisoners was taken, since the Red Army had withdrawn their main forces from the salient before the German attack began. After a week of effort the German armoured divisions were seriously reduced by the well-prepared Soviet antitank defenses in the salient. On July 12, as the Germans began to pull out, the Soviets launched a counteroffensive upon the German positions in the salient and met with great success, taking Orël on August 5. By this time the Germans had lost 2,900 tanks and 70,000 men in the Battle of Kursk, which was the largest tank battle in history. The Soviets continued to advance steadily, taking Belgorod and then Kharkov. In September the Soviet advance was accelerated, and by the end of the month the Germans in the Ukraine had been driven back to the Dnepr.

The Southwest and South Pacific, June–October 1943. A Pacific military conference held in Washington, D.C., in March 1943 produced a new schedule of operations calling for the development of some counterattacks against the Japanese. The reduction of the threat from the large Japanese naval base at Rabaul, by encirclement if not by the capture of that stronghold, was a primary objective for MacArthur.

Between June 22 and June 30, 1943, two U.S. regiments invaded Woodlark and Kiriwina islands (northeast of the tip of Papua), whence aircraft could range over not only the Coral Sea but also the approaches to Rabaul and to the Solomons. At the same time, U.S. and Australian units advanced from Buna along the coast of New Guinea toward Lae and Salamaua, while other Australian forces simultaneously advanced from Wau in the hinterland; and in the night of June 29–30, U.S. forces secured Nassau Bay as a base for further advances against the same positions.

U.S. landings on New Georgia and on Rendova in the Solomons, however, also made in the night of June 29–30, provoked the Japanese into strong counteraction: between July 5 and July 16, in the battles of Kula Gulf and of Kolombangara, the Allies lost one cruiser and two destroyers and had three more cruisers crippled; and the Japanese, though they lost a cruiser and two destroyers,

were able to land considerable reinforcements (from New Britain). Only substantial counter-reinforcement secured the New Georgia group of islands for the Allies, who, moreover, began on August 15 to extend their operation to the island of Vella Lavella also. In the last two months of the struggle, which ended with the Japanese evacuation of Vella Lavella on October 7, the Japanese sank an Allied destroyer and crippled two more but lost a further six of their own; and their attempt to defend the Solomon Islands cost them 10,000 lives, as against the Americans' 1,150 killed and 4,100 wounded.

Meanwhile, U.S. planes on August 17–18 had attacked Japanese bases at Wewak (on the New Guinea coast far to the west of Lae) and destroyed more than 200 aircraft there. On September 4 an Australian division landed near Lae, and the next day U.S. paratroops dropped at Nadzab, above Lae on the Markham River, where they were soon joined by an Australian airborne division. Salamaua fell to the Allies on September 12, Lae on September 16, and Finschhafen, on the Huon Peninsula behind Lae, on October 2. On Sept. 30, 1943, the Japanese made a new policy decision: a last defense line was to be established from western New Guinea and the Carolines to the Marianas by spring 1944, to be held at all costs, and also to be used as a base for counterattacks. Japanese last defense line

The Allied landings in Europe and the defeat of the Axis powers

Sicily and the fall of Mussolini, July–August 1943. Hitler's greatest strategic disadvantage in opposing the Allies' imminent reentry into Europe lay in the immense stretch of Germany's conquests; from the west coast of France to the east coast of Greece. It was difficult for him to gauge where the Allies would strike next. The Allies' greatest strategic advantage lay in the wide choice of alternative objectives and in the powers of distraction they enjoyed through their superior sea power. Hitler, while always having to guard against a cross-Channel invasion from England's shores, had cause to fear that the Anglo-American armies in North Africa might land anywhere on his southern front between Spain and Greece.

Having failed to save its forces in Tunisia, the Axis had only 10 Italian divisions of various sorts and two German panzer units stationed on the island of Sicily at midsummer 1943. The Allies, meanwhile, were preparing to throw some 478,000 men into the island—150,000 of them in the first three days of the invasion. Under the supreme command of Alexander, Montgomery's British 8th Army and Patton's U.S. 7th Army were to be landed on two stretches of beach 40 miles long, 20 miles distant from one another, the British in the southeast of the island, the Americans in the south. The Allies' air superiority in the Mediterranean theatre was so great by this time—more than 4,000 aircraft against some 1,500 German and Italian ones—that the Axis bombers had been withdrawn from Sicily in June to bases in north-central Italy.

On July 10 Allied seaborne troops landed on Sicily. The coastal defenses, manned largely by Sicilians unwilling to turn their homeland into a battlefield for the Germans' sake, collapsed rapidly enough. The British forces had cleared the whole southeastern part of the island in the first three days of the invasion. The Allies' drive toward Messina then took the form of a circuitous movement by the British around Mount Etna in combination with an eastward drive by the Americans, who took Palermo, on the western half of the northern coast, on July 22. Meanwhile, the German armoured strength in Sicily had been reinforced.

After the successive disasters sustained by the Axis in Africa, many of the Italian leaders were desperately anxious to make peace with the Allies. The invasion of Sicily, representing an immediate threat to the Italian mainland, prompted them to action. On the night of July 24–25, 1943, when Mussolini revealed to the Fascist Grand Council that the Germans were thinking of evacuating the southern half of Italy, the majority of the council voted for a resolution against him, and he resigned his powers. On The arrest of Mussolini

German and Allied movements in Europe from the end of 1942 to 1945, and (inset) the Normandy Invasion, June–July 1944.

From *Grosser Historischer Weltatlas*, vol 3. *Neuzeit*, 2nd ed. (1967). Bayerischer Schulbuch-Verlag, Munich

July 25 the king, Victor Emmanuel III, ordered the arrest of Mussolini and entrusted Marshal Pietro Badoglio with the formation of a new government. The new government entered into secret negotiations with the Allies, despite the presence of sizable German forces in Italy.

A few days after the fall of Mussolini, Field Marshal Albert Kesselring, the German commander in chief in Italy, decided that the Axis troops in Sicily must be evacuated; the local Italian commander thought so too. While rearguard actions held up the Allies at Adrano (on the western face of Mount Etna) and at Randazzo (to the north), 40,000 Germans and 60,000 Italian troops were safely withdrawn across the Strait of Messina to the mainland, mostly in the week ending on Aug. 16, 1943—the day before the Allies' entry into Messina.

The Allies sustained about 22,800 casualties in their conquest of Sicily. The Axis powers suffered about 165,000 casualties, of whom 30,000 were Germans.

The Quadrant Conference (Quebec I). The success of the Sicilian operation and the fall of Mussolini converted

the American military and political leadership into supporters of a campaign in Italy. Furthermore, Lieutenant General Sir Frederick Morgan, who after Casablanca had been designated chief of staff to the Supreme Allied Commander (COSSAC), produced a detailed and realistic plan for the long-envisaged invasion of France from Great Britain, thus enabling the U.S. strategists to calculate more precisely how much of the Allies' resources were needed for that purpose and how much could be spared for operations in the Mediterranean and for the Pacific. With regard to the Pacific, plans sponsored by Admiral Nimitz for operations against the Gilbert and Marshall islands apart from the enterprise against Rabaul were approved early in August 1943.

The new turn of strategical thought necessitated a new Anglo-U.S. conference, which took place in Quebec in mid-August 1943 and was code-named "Quadrant." After vigorous debate, the question of the timing of "Overlord" was eventually left open, but it was agreed that the strength of the assault force should exceed the original estimate by

25 percent, that the cross-Channel landing should be supported by a landing in southern France, and that a U.S. officer should be in command of "Overlord." It was also decided that a new Southeast Asia theatre of war should be organized, under British command.

The Allies' invasion of Italy and the Italian volte-face, 1943. From Sicily, the Allies had a wide choice of directions for their next offensive. Calabria, the "toe" of Italy, was the nearest and most obvious possible destination, and the "shin" was also vulnerable; and the "heel" was also very attractive. The two army corps of Montgomery's 8th Army crossed the Strait of Messina and landed on the "toe" of Italy on Sept. 3, 1943; but, though the initial resistance was practically negligible, they made only very slow progress, as the terrain, with only two good roads running up the coasts of the great Calabrian "toe" prevented the deployment of large forces. On the day of the landing, however, the Italian government at last agreed to the Allies' secret terms for a capitulation. It was understood that Italy would be treated with leniency in direct proportion to the part that it would take, as soon as possible, in the war against Germany. The capitulation was announced on September 8.

The landing on the "shin" of Italy, at Salerno, just south of Naples, was begun on September 9, by the mixed U.S.–British 5th Army, under General Mark Clark. Transported by 700 ships, 55,000 men made the initial assault, and 115,000 more followed up. At first they were faced only by the German 16th Panzer Division; but Kesselring, though he had only eight weak divisions to defend all southern and central Italy, had had time to plan since the fall of Mussolini and had been expecting a blow at the "shin." His counterstroke made the success of the Salerno landing precarious for six days, and it was not until October 1 that the 5th Army entered Naples.

By contrast, the much smaller landing on the "heel" of Italy, which had been made on September 2 (the day preceding the invasion of the "toe"), took the Germans by surprise. Notwithstanding the paucity of its strength in men and in equipment, the expedition captured two good ports, Taranto and Brindisi, in a very short time; but it lacked the resources to advance promptly. Nearly a fortnight passed before another small force was landed at Bari, the next considerable port north of Brindisi, to push thence unopposed into Foggia.

It was the threat to their rear from the "heel" of Italy and from Foggia that had induced the Germans to fall back from their positions defending Naples against the 5th Army. When the Italian government, in pursuance of a Badoglio–Eisenhower agreement of September 29, declared war against Germany on Oct. 13, 1943, Kesselring was already receiving reinforcements and consolidating the German hold on central and northern Italy. The 5th Army was checked temporarily on the Volturno River, only 20 miles north of Naples, then more lastingly on the Garigliano River, while the 8th Army, having made its way from Calabria up the Adriatic coast, was likewise held on the Sangro River. Autumn and midwinter passed without the Allies' making any notable impression on the Germans' Gustav Line, which ran for 100 miles from the mouth of the Garigliano through Cassino and over the Apennines to the mouth of the Sangro.

The western Allies and Stalin: Cairo and Tehrān, 1943. Relations between the western Allies and the U.S.S.R. were still delicate. Besides their inability to satisfy Soviet demands for convoys of supplies and for an early invasion of France, the Americans and the British were embarrassed by the discrepancy between their political war aims and Stalin's.

The longest-standing difference was about Poland. While Poles were still fighting on the Allies' side and acknowledging the authority of General Władysław Sikorski's London-based Polish government in exile, Stalin was trying to get the Allies to consent to the U.S.S.R.'s retention, after the war, of all the territory taken from Poland by virtue of the German–Soviet pacts of 1939. On Jan. 16, 1943, the Soviet government announced that Poles from the border territories in dispute were being treated as Soviet citizens and drafted into the Red Army. On April 25, the Soviet government severed relations with the London Poles, and Moscow subsequently began to build up its own puppet government for postwar Poland.

Besides the quarrel over Poland, the western Allies and the U.S.S.R. were also at variance with regard to the postwar fate of other European states still under German domination; but the Americans and the British were really more interested in maintaining the Soviet war effort against Germany than in insisting, at the risk of offense to Stalin, on the detailed application of their own loudly but vaguely enunciated war aims.

Sextant, the conference of Nov. 22–27, 1943, for which Churchill, Roosevelt, and Chiang Kai-shek met in Cairo, was, on Roosevelt's insistence, devoted mainly to discussing plans for a British–U.S.–Chinese operation in northern Burma. Little was produced by Sextant except the Cairo Declaration, published on December 1, a further statement of war aims. It prescribed inter alia that Japan was to surrender all Pacific islands acquired since 1914, to retrocede Manchuria, Formosa, and the Pescadores to China, and to give up all other territory "taken by violence and greed"; and, in addition, it was stipulated that Korea was in due course to become independent.

From Cairo, Roosevelt and Churchill went to Tehrān, to meet Stalin at the Eureka conference of November 28–December 1. Stalin renewed the Soviet promise of military intervention against Japan, but he primarily wanted an assurance that "Overlord" (the invasion of France) would indeed take place in 1944. Reassured about this by Roosevelt, he declared that the Red Army would attack simultaneously on the Eastern Front. On the political plane, Stalin now demanded the Baltic coast of East Prussia for the U.S.S.R. as well as the territories annexed in 1939–40. The main communique of the conference was accompanied by a joint declaration guaranteeing the postwar restoration of Iran. Returning to Cairo, Roosevelt and Churchill spent six more days, December 2–7, in staff talks to compose their differences on strategy. They finally agreed that "Overlord" (with Eisenhower in command) should have first claim on resources.

German strategy, from 1943. From late 1942 German strategy, every feature of which was determined by Hitler, was solely aimed at protecting the still very large area under German control—most of Europe and part of North Africa—against a future Soviet onslaught on the Eastern Front and against future Anglo-U.S. offensives on the southern and western fronts. The Germans' vague hopes that the Allies would shrink from such costly tasks or that the "unnatural" coalition of western capitalism and Soviet Communism would break up before achieving victory were disappointed; and so Hitler, in accordance with his dictum that "Germany shall either be a world power or not be at all," consciously resolved to preside over the downfall of the German nation. He gave inflexible orders whereby whole armies were made to stand their ground in tactically hopeless positions and were forbidden to surrender under any circumstances. The initial success of this strategy in preventing a German rout during the Soviet winter counteroffensive of 1941–42 had blinded Hitler to its impracticability in the very different military circumstances on the Eastern Front by 1943, by which time the Germans simply lacked sufficient numbers of troops to defend an extremely long front against much more numerous Soviet forces. (By December 1943 the 3,000,000 German troops there were opposed by about 5,500,000 Soviet troops.)

The strategy of keeping his armies stationary was made easier for Hitler by the complete ascendancy he had achieved over his generals, who disputed with Hitler only at the risk of losing their commands or worse. Frequent changes were made in the command of the various army groups and armies, with the result that during 1943–44 most of the talented commanders who had been associated with Germany's past successes were removed, and everyone who was suspected of a critical attitude at headquarters was silenced.

From late 1943 on, Hitler's strategy, which from a political standpoint remains inexplicable to most Western historians, was to strengthen the German forces in west-

ern Europe at the expense of those on the Eastern Front. In view of the danger of the great Anglo-U.S. invasion of western Europe that seemed imminent by early 1944, the loss of some part of his eastern conquests evidently seemed to Hitler to be less serious. Hitler continued to insist on the primacy of the war in the west after the start of the Allied invasion of northern France in June 1944, and while his armies made strenuous efforts to contain the Allied bridgehead in Normandy for the next two months, Hitler accepted the annihilation of the German Army Group Centre on the Eastern Front by the Soviet summer offensive (from June 1944), which brought the Red Army in a few weeks' time to the Vistula River and the borders of East Prussia. But the Western Front likewise crumbled in a few weeks, whereupon the Allies advanced to Germany's western borders. Then, still adhering to his guiding principle, Hitler assembled on the Western Front all that was left of his forces there and tried to drive the British and Americans back in what became known as the Battle of the Bulge. This campaign had some successes but meant that Germany's last battleworthy units were used on the Western Front while the Red Army, heavily outnumbering the remaining German troops in the east, resumed its drive on the eastern frontiers of Germany and reached the Oder River by the end of January 1945.

The Eastern Front, October 1943–April 1944. By the end of the first week of October 1943, the Red Army had established several bridgeheads on the right bank of the Dnepr River. Then, while General N.F. Vatutin's drive against Kiev was engaging the Germans' attention, General Ivan Stepanovich Konev suddenly pushed so far forward from the Kremenchug bridgehead (more than halfway downstream between Kiev and Dnepropetrovsk) that the German forces within the great bend of the Dnepr to the south would have been isolated if Manstein had not stemmed the Soviet advance just in time to extricate them. By early November the Red Army had reached the mouth of the Dnepr also, and the Germans in the Crimea were isolated. Kiev, too, fell to Vatutin on November 6, Zhitomir, 80 miles to the west, and Korosten, north of Zhitomir, in the next 12 days. Farther north, however, the Germans, who had already fallen back from Smolensk to a line covering the upper Dnepr, repelled with little difficulty five rather predictable Soviet thrusts toward Minsk in the last quarter of 1943.

Vatutin's forces from the Zhitomir–Korosten sector advanced westward across the prewar Polish frontier on Jan. 4, 1944; and, though another German flank attack, by troops drawn from adjacent fronts, slowed them down, they had reached Lutsk, 100 miles farther west, a month later. Vatutin's left wing, meanwhile, wheeled southward to converge with Konev's right, so that 10 German divisions were encircled near Korsun, on the Dnepr line south of Kiev. Vainly trying to save those 10 divisions, the Germans had to abandon Nikopol, in the Dnepr bend far to the south, with its valuable manganese mines.

March 1944 saw a triple thrust by the Red Army: Zhukov, succeeding to Vatutin's command, drove southwest toward Tarnopol, to outflank the Germans on the upper stretches of the southern Bug River. General Rodion Yakovlevich Malinovsky, in the south, advanced across the mouth of the latter river from that of the Dnepr; and between them Konev, striking over the central stretch of the Bug, passed the Dnestr, 70 miles ahead, and succeeded in crossing it. When Zhukov had crossed the upper Prut River and Konev was threatening Iaşi on the Moldavian stretch of the river, the Carpathian Mountains were the only natural barrier remaining between the Red Army and the Hungarian Plain. German troops occupied Hungary on March 20, since Hitler suspected that the Hungarian regent, Admiral Miklós Horthy, might not resist the Red Army to the utmost.

A German counterstroke from the Lwów area of southern Poland against Zhukov's extended flank early in April not only put an end to the latter's overhasty pressure on the Tatar (Yablonitsky) Pass through the Carpathians but also made possible the withdrawal of some of the German forces endangered by the Red Army's March operation. Konev, too, was halted in front of Iaşi; but his left swung

[margin: The Soviet advance into Poland]

[margin: The German occupation of Hungary]

southward down the Dnestr to converge with Malinovsky's drive on Odessa. That great port fell to the Red Army on April 10. On May 9 the Germans in the Crimea abandoned Sevastopol, caught as they were between Soviet pincers from the mainland north of the isthmus and from the east across the Strait of Kerch.

At the northern end of the Eastern Front, a Soviet offensive in January 1944 had been followed by an orderly German retreat from the fringes of the long-besieged Leningrad area to a shorter line exploiting the great lakes farther to the south. The retreat was beneficial to the Germans but sacrificed their land link with the Finns, who now found themselves no better off than they had been in 1939–40. Finland in February 1944 sought an armistice from the U.S.S.R., but the latter's terms proved unacceptable.

The war in the Pacific, October 1943–August 1944. Considering that it might be necessary for them to invade Japan proper, the Allies drew up new plans in mid-1943. The main offensive, it was decided, should be from the south and from the southeast, through the Philippines and through Micronesia (rather than from the Aleutians in the North Pacific or from the Asian mainland). While occupation of the Philippines would disrupt Japanese communications with the East Indian isles west of New Guinea and with Malaya, the conquest of Micronesia, from the Gilberts by way of the Marshalls and Carolines to the Marianas, would not only offer the possibility of drawing the Japanese into a naval showdown but also win bases for heavy air raids on the Japanese mainland prior to invasion.

For the approach to the Philippines, it was prerequisite, on the one hand, to complete the encirclement of Rabaul, thereby nullifying the threat from the Japanese positions in the Solomon Islands and in the Bismarck Archipelago (New Britain, New Ireland, etc.) and, on the other, to reduce the Japanese hold on western New Guinea. Great emphasis, however, was put on the advance across the central Pacific through Micronesia, to be begun via the Gilberts.

The encirclement of Rabaul. Allied moves to isolate the large Japanese garrison on Rabaul proceeded by land and air. The encirclement of Rabaul by land began during October and November 1943 with the capture by New Zealand troops of the Treasury Islands in the Solomons and was accompanied on November 1 by a U.S. landing at Empress Augusta Bay on the west of Bougainville. U.S. reinforcements subsequently repulsed Japanese counterattacks in December, when they sank two destroyers, and in March 1944, when they killed almost 6,000 men. What remained of the Japanese garrison on Bougainville was no longer capable of fighting, though it did not surrender until the end of the war.

Continuing the approach to Rabaul, U.S. troops landed on December 15 at Arawe on the southwestern coast of New Britain, thereby distracting Japanese attention from Cape Gloucester, on the northwestern coast, where a major landing was made on December 26. By Jan. 16, 1944, the airstrip at Cape Gloucester had been captured and defense lines set up. Talasea, halfway to Rabaul, fell in March 1944. The conquest of western New Britain secured Allied control of the Vitiaz and Dampier straits between that island and New Guinea.

By constructing air bases on each island that they captured, the Allies systematically blocked any westward movement that the Japanese might have made: New Zealand troops took the Green Islands southeast of New Guinea on February 15; and U.S. forces invaded Los Negros in the Admiralty Islands on February 29 and captured Manus on March 9.

With the fall of the Emirau Islands on March 20, the Allies' stranglehold on Rabaul and Kavieng was practically complete, so that they could thenceforth disregard the 100,000 Japanese immobilized there.

Western New Guinea. Before they could push northward to the Philippines, the Allies had to subdue Japanese-held western New Guinea. U.S. troops took Saidor, on the Huon Peninsula, on Jan. 2, 1944, and established an air base there; and the Australians took Sio, to the east of

Saidor, on January 16. Then reinforcements were landed at Mindiri, west of Saidor, on March 5, and Australian infantry began to move westward up the coast, to take Bogadjim, Madang, and Alexishafen.

Bypassing Hansa Bay (which was eventually captured on June 15) and Wewak, whither the Japanese had retreated, the Allies, on April 22, 1944, made two simultaneous landings at Hollandia: having in the past weeks already destroyed 300 Japanese planes, they captured the airfields there in four days' time. In the following months Hollandia was converted into a major base and command post for the Southwest Pacific area. The Allies also took Aitape, on the coast east of Hollandia, and held it against counterattacks by more than 200,000 Wewak-based Japanese during July and August. Biak, the isle guarding the entrance to Geelvink Bay, west of Hollandia, was invaded by U.S. troops on May 27, 1944; but the Japanese defense of it was maintained until early August. Though westernmost New Guinea fell likewise to the Allies in August 1944, the Japanese garrison at Wewak held out until May 10, 1945.

Hollandia taken by the Allies

The central Pacific. Though the U.S. Joint Chiefs of Staff envisaged no major offensive westward across the Pacific toward Formosa until mid-1944, they nevertheless decided to launch a limited offensive in the central Pacific in 1943, hoping thereby both to speed the pace of the war and to draw the Japanese away from other areas. Accordingly, Nimitz' central Pacific forces invaded the Gilberts on Nov. 23, 1943. Makin fell easily, but well-fortified Japanese defenses on Tarawa cost the U.S. Marines 1,000 killed and 2,300 wounded. Japanese losses in the Gilberts totaled about 8,500 men.

Having been forced to cede the Gilberts, the Japanese elected next to defend the Marshalls, in order both to absorb Allied forces and to strain the latters' extended lines of supply. Nimitz subjected Kwajalein Atoll, which he chose first to attack, to so heavy a preliminary bombardment that the U.S. infantry could land on it on Jan. 31, 1944; and U.S. forces moved on to Eniwetok on February 17.

In support of the landings on the Marshalls, the U.S. fleet on Feb. 17, 1944, started a series of day and night attacks against the Japanese base at Truk in the Caroline Islands, where they destroyed some 300 aircraft and 200,000 tons of merchant shipping. Henceforth, the Allies could confidently ignore Truk and bypass it.

The Allies' next objective, for which they required more than 500 ships and 125,000 troops, was to reduce the Mariana Islands, lying 1,000 miles from Eniwetok and 3,500 miles from Pearl Harbor. Against this threat, after the destruction at Truk, the Japanese hastily drew up a new defense plan, "Operation A," relying on their remaining 1,055 land-based aircraft in the Marianas, in the Carolines, and in western New Guinea and on timely and decisive intervention by a sea force, which should include nine aircraft carriers with 450 aircraft. But in the spring of 1944 the Japanese air strength was still further depleted, and, moreover, on March 31 the sponsor of the plan, Admiral Koga Mineichi (Yamamoto's successor), and his staff were killed in an air disaster. When, on June 15, two U.S. Marine divisions went ashore on Saipan Island in the Marianas, the 30,000 Japanese defenders put up so fierce a resistance that an army division was needed to reinforce the Marines. Using the same defensive tactics as on other small islands, the Japanese had fortified themselves in underground caves and bunkers that afforded protection from American artillery and naval bombardment. Notwithstanding this, the Japanese defenders were gradually compressed into smaller and smaller pockets, and they themselves ended most organized resistance with a suicidal counterattack on July 7, the largest of its kind during the war.

Saipan taken

The loss of Saipan was such a disaster for Japan that when the news was announced in Tokyo the prime minister, Tōjō Hideki, and his entire Cabinet resigned. To realists in the Japanese high command, the loss of the Marianas spelled the ultimate loss of the war, but no one dared say so. Tōjō's Cabinet was succeeded by that of General Koiso Kuniaki, which was pledged to carrying on the fight with renewed vigour.

Air power enthusiasts have called the conquest of Saipan "the turning point of the war in the Pacific," for it enabled the United States to establish air bases there for the big B-29 bombers, which had been developed for the specific purpose of bombing Japan. The first flight of 100 B-29s took off from Saipan on Nov. 24, 1944, and bombed Tokyo, the first bombing raid on the Japanese capital since 1942.

While the Japanese were still resisting on Saipan, the Japanese Combined Fleet, under Admiral Ozawa Jisaburō, was approaching from Philippine and East Asian anchorages, in accordance with "Operation A," to challenge the U.S. 5th Fleet, under Admiral Raymond Spruance. Ozawa, with only nine aircraft carriers against 15 for the United States, was obviously inferior in naval power, but he counted heavily on help from land-based aircraft on Guam, Rota, and Yap. The encounter, which took place west of the Marianas and is known as the Battle of the Philippine Sea, has been called the greatest carrier battle of the war. It began on June 19 when Ozawa sent 430 planes in four waves against Spruance's ships. The result was a disaster for the Japanese. U.S. airmen shot down more than 300 planes and sank two carriers, and as the Japanese fleet retreated northward toward Okinawa it lost another carrier and almost 100 more planes. The United States lost about 130 planes. The hasty and incomplete training of the Japanese pilots and the inadequate armour plating of their planes were decisive factors in the numerous aerial combats of this battle, which was ultimately of more strategic importance than the fall of Saipan. Nimitz' forces could thereafter occupy other major islands in the Marianas: Guam on July 21 and Tinian on July 24. The Marianas cost the Japanese 46,000 killed or captured, the Americans only 4,750 killed.

The Battle of the Philippine Sea

The Burmese frontier and China, November 1943–summer 1944. For the dry season of 1943–44 both the Japanese and the Allies were resolved on offensives in Southeast Asia. On the Japanese side, Lieutenant General Kawabe Masakazu planned a major Japanese advance across the Chindwin River, on the central front, in order to occupy the plain of Imphāl and to establish a firm defensive line in eastern Assam. The Allies, for their part, planned a number of thrusts into Burma: Stilwell's NCAC forces, including his three Chinese divisions and "Merrill's Marauders" (U.S. troops trained by Wingate on Chindit lines), were to advance against Mogaung and Myitkyina; while Slim's 14th Army was to launch its XV Corps southeastward into Arakan and its IV Corps eastward to the Chindwin. Because the Japanese had habitually got the better of advanced British forces by outflanking them, Slim formulated a new tactic to ensure that his units would stand against attack in the forthcoming campaign, even if they should be isolated: they were to know that, when ordered to stand, they could certainly count both on supplies from the air and on his use of reserve troops to turn the situation against the Japanese attackers.

On the southern wing of the Burmese front, the XV Corps's Arakan operation, launched in November 1943, had achieved most of its objectives by the end of January 1944. When the Japanese counterattack surrounded one Indian division and part of another, Slim's new tactic was brought into play, and the Japanese found themselves crushed between the encircled Indians and the relieving forces.

The Japanese crossing of the Chindwin into Assam, on the central Burmese front, when the fighting in Arakan was dying down, played into Slim's hands, since he could now profit from the Allies' superiority in aircraft and in tanks. The Japanese were able to approach Imphāl and to surround Kohīma, but the British forces protecting these towns were reinforced with several Indian divisions that were taken from the now-secure Arakan front. With air support, Slim's reinforced forces now defended Imphāl against multiple Japanese thrusts and outflanking movements until, in mid-May 1944, he was able to launch two of his divisions into an offensive eastward, while still containing the last bold effort of the Japanese to capture Imphāl. By June 22 the 14th Army had averted the Japanese menace to Assam and won the initiative for its own advance into Burma. The Battle of Imphāl–Kohīma

cost the British and Indian forces 17,587 casualties (12,600 of them sustained at Imphāl), the Japanese forces 30,500 dead (including 8,400 from disease) and 30,000 wounded.

On the northern Burmese front, Stilwell's forces were already approaching Mogaung and Myitkyina before the southern crisis of Imphāl–Kohima; and the subsidiary Chindit operation against Indaw was going well ahead when, on March 24, 1944, Wingate himself was killed in an air crash. Meanwhile, Chiang Kai-shek was constrained by U.S. threats of a suspension of lend-lease to finally authorize some action by the 12 divisions of his Yunnan Army, which on May 12, 1944, with air support, began to cross the Salween River westward in the direction of Myitkyina, Bhamo, and Lashio. Myitkyina airfield was taken by Stilwell's forces, with "Merrill's Marauders," on May 17, Mogaung was taken by the Chindits on June 26, and finally Myitkyina itself was taken by Stilwell's Chinese divisions on August 3. All of northwest and much of northern Burma was now in Allied hands.

In China proper, a Japanese attack toward Ch'ang-sha, begun on May 27, won control not only of a further stretch of the north–south axis of the Peking–Han-K'ou railroad but also of several of the airfields from which the Americans had been bombing the Japanese in China and were intending to bomb them in Japan.

The Italian front, 1944. The Allies' northward advance up the Italian peninsula to Rome was still blocked by Kesselring's Gustav Line, which was hinged on Monte Cassino. To bypass that line, the Allies landed some 50,-000 seaborne troops, with 5,000 vehicles, at Anzio, only 33 miles south of Rome, on Jan. 22, 1944. The landing surprised the Germans and met, at first, with very little opposition; but, instead of driving on over the Alban Hills to Rome at once, the force at Anzio spent so much time consolidating its position there that Kesselring was able, with his reserves, to develop a powerful counteroffensive against it on February 3. The beachhead was thereby reduced to a very shallow dimension, while the defenses at Monte Cassino held out unimpaired against a new assault by Clark's 5th Army.

For a final effort against the Gustav Line, Alexander decided to shift most of the 8th Army, now commanded by Major General Sir Oliver Leese, from the Adriatic flank of the peninsula to the west, where it was to strengthen the 5th Army's pressure around Monte Cassino and on the approaches to the valley of the Liri (headstream of the Garigliano). The combined attack, which was started in **Battle of** the night of May 11–12, 1944, succeeded in breaching the **Monte** German defenses at a number of points between Cassino **Cassino** and the coast. Thanks to this victory, the Americans could push forward up the coast, while the British entered the valley and outflanked Monte Cassino, which fell to a Polish corps of the 8th Army on May 18. Five days later, the Allies' force at Anzio struck out against the investing Germans (whose strength had been diminished in order to reinforce the Gustav Line); and by May 26 it had achieved a breakthrough. When the 8th Army's Canadian Corps penetrated the last German defenses in the Liri Valley, the whole Gustav Line began to collapse.

Concentrating all available strength on his left wing, Alexander pressed up from the south to effect a junction with the troops thrusting northward from Anzio. The Germans in the Alban Hills could not withstand the massive attack. On June 5, 1944, the Allies entered Rome. The propaganda value of their occupying the Eternal City, Mussolini's former capital, was offset, however, by an unforeseen strategical reality: Kesselring's forces retreated not in the expected rout but gradually, to the line of the Arno River; Florence, 160 miles north of Rome, did not fall to the Allies until August 13; and by that time the Germans had made ready yet another chain of defenses, the Gothic Line, running from the Tyrrhenian coast midway between Pisa and La Spezia, over the Apennines in a reversed S curve, to the Adriatic coast between Pesaro and Rimini.

Alexander might have made more headway against Kesselring's new front if some of his forces had not been subtracted, in August 1944, for the American-sponsored but eventually unnecessary invasion of southern France ("Operation Anvil," finally renamed "Dragoon" [see be-

low]). As it was, the 8th Army, switched back from the **Alex-** west to the Adriatic coast, achieved only an indecisive **ander's** breakthrough toward Rimini. After this September offen- **offensive** sive, the autumn rains set in, to make even more difficult **weakened** Alexander's indirect movements, against Kesselring's resolute opposition, toward the mouth of the Po River.

DEVELOPMENTS FROM SUMMER 1944 TO AUTUMN 1945

The Allied invasions of western Europe, June–November 1944. The German Army high command had long been expecting an Allied invasion of northern France but had no means of knowing where precisely the stroke would come: while Rundstedt, commander in chief in the west, thought that the landings would be made between Calais and Dieppe (at the narrowest width of the Channel between England and France), Hitler prophetically indicated the central and more westerly stretches of the coast of Normandy as the site of the attack; and Rommel, who was in charge of the forces on France's Channel coast, finally came around to Hitler's opinion. The fortifications of those stretches were consequently improved, but Rundstedt and Rommel still took different views about the way in which the invasion should be met: while Rundstedt recommended a massive counterattack on the invaders after their landing, Rommel, fearing that Allied air supremacy might interfere fatally with the adequate massing of the German forces for such a counterattack, advocated instead immediate action on the beaches against any attempted landing. The Germans had 59 divisions spread over western Europe from the Low Countries to the Atlantic and Mediterranean coasts of France; but approximately half of this number was static, and the remainder included only 10 armoured or motorized divisions.

Postponed from May, the western Allies' "Operation Overlord," their long-debated invasion of northern France, took place on June 6, 1944—the war's most celebrated D-Day—when 156,000 men were landed on the beaches of Normandy between the Orne estuary and the southeastern end of the Cotentin Peninsula: 83,000 British and Cana- **Normandy** dian troops on the eastern beaches, 73,000 Americans on **invaded** the western. Under Eisenhower's supreme direction and Montgomery's immediate command, the invading forces initially comprised the Canadian 1st Army (Lieutenant General Henry Duncan Graham Crerar); the British 2nd Army (Lieutenant General Sir Miles Dempsey); and the British 1st and 6th airborne divisions, the U.S. 1st Army, and the U.S. 82nd and 101st airborne divisions (all under Lieutenant General Omar N. Bradley).

By 9:00 AM on D-Day the coastal defenses were generally breached, but Caen, which had been scheduled to fall on D-Day and was the hinge of an Allied advance, held out until July 9, the one panzer division already available there on June 6 having been joined the next day by a second. Though the heavy fighting at Caen attracted most of the German reserves, the U.S. forces in the westernmost sector of the front likewise met a very stubborn resistance. But when they had taken the port of Cherbourg on June 26 and proceeded to clear the rest of the Cotentin, they could turn southward to take Saint-Lô on July 18.

The Allies could not have made such rapid progress in northern France if their air forces had not been able to interfere decisively with the movement of the German reserves. Allied aircraft destroyed most of the bridges over the Seine River to the east and over the Loire to the south. The German reserves thus had to make long detours in order to reach the Normandy battle zone and were so constantly harassed on the march by Allied strafing that they suffered endless delays and only arrived in driblets. And even where reserves could have been brought up, their movement was sometimes inhibited by hesitation and dissension on the Germans' own side. Hitler, though he had rightly predicted the zone of the Allies' landings, came to mistakenly believe, after D-Day, that a second and larger invasion was to be attempted east of the Seine and so was reluctant to allow reserves to be moved westward over that river. He also forbade the German forces already engaged in Normandy to retreat in time to make an orderly withdrawal to new defenses.

Rundstedt, meanwhile, was slow in obtaining Hitler's

authority for the movement of the general reserve's SS panzer corps from its position north of Paris to the front; and Rommel, though he made prompt use of the forces at hand, had been absent from his headquarters on D-Day itself, when a forecast of rough weather had seemed to make a cross-Channel invasion unlikely. Subsequently, Rundstedt's urgent plea for permission to retreat provoked Hitler, on July 3, to appoint Kluge as commander in chief in the west in Rundstedt's place; and Rommel was badly hurt on July 17, when his car crashed under attack from Allied planes.

There was something else, besides the progress of the Allies, to demoralize the German commanders—the failure and the aftermath of a conspiracy against Hitler. Alarmed at the calamitous course of events and disgusted by the crimes of the Nazi regime, certain conservative but anti-Nazi civilian dignitaries and military officers had formed themselves into a secret opposition, with Karl Friedrich Goerdeler (a former chief mayor of Leipzig) and Colonel General Ludwig Beck (a former chief of the army general staff) among its leaders. From 1943 this opposition canvased the indispensable support of the active military authorities with some notable success: General Friedrich Olbricht (chief of the General Army Office) and several of the serving commanders, including Rommel and Kluge, became implicated to various extents. Apart from General Henning von Tresckow, however, the group's most dynamic member was Colonel Graf Claus von Stauffenberg, who as chief of staff to the chief of the army reserve from July 1, 1944, had access to Hitler. Finally, it was decided to kill Hitler and to use the army reserve for a coup d'état in Berlin, where a new regime under Beck and Goerdeler should be set up. On July 20, therefore, Stauffenberg left a bomb concealed in a briefcase in the room where Hitler was conferring at his headquarters in East Prussia. The bomb duly exploded; but Hitler survived, and the coup in Berlin miscarried. The Nazi reaction was savage: besides 200 immediately implicated conspirators, 5,000 people who were more remotely linked with the plot or were altogether unconnected with it were put to death. Kluge committed suicide on August 17, Rommel on October 14. Fear permeated and paralyzed the German high command in the weeks that followed.

On July 31, 1944, the Americans on the Allies' right, newly supported by the landing of the U.S. 3rd Army under Patton, broke through the German defenses at Avranches, the gateway from Normandy into Brittany. On August 7 a desperate counterattack by four panzer divisions from Mortain, east of Avranches, failed to seal the breach, and American tanks poured southward through the gap and flooded the open country beyond. Though some of the U.S. forces were then swung southwestward in the hope of seizing the Breton ports in pursuance of the original prescription of "Overlord" and though some went on in more southerly directions toward the crossings of the Loire, others were wheeled eastward—to trap, in the Falaise "pocket," a large part of the German forces retreating southward from the pressure of the Allies' left at Caen. The Americans' wide eastward flanking maneuver after the breakout speedily produced a general collapse of the German position in northern France.

Meanwhile, more and more Allied troops were being landed in Normandy. On August 1, two army groups were constituted: the 21st (comprising the British and Canadian armies) under Montgomery, and the 12th (for the Americans) under Bradley. By the middle of August an eastward wheel wider than that which had cut off the Falaise pocket had brought the Americans to Argentan, southeast of Falaise and level with the British and Canadian advance on the left (north) of the Allies' front, so that a concerted drive eastward could now be launched; and on August 19 a U.S. division successfully crossed the Seine at Mantes-Gassicourt. Already on August 17 the Americans on the Loire had taken Orléans. The clandestine French Resistance in Paris rose against the Germans on August 19; and a French division under General Jacques Leclerc, pressing forward from Normandy, received the surrender of the German forces there and liberated the city on August 25.

The German forces would have had ample time to pull back to the Seine River and to form a strong defensive barrier line there had it not been for Hitler's stubbornly stupid orders that there should be no withdrawal. It was his folly that enabled the Allies to liberate France so quickly. The bulk of the German armoured forces and many infantry divisions were thrown into the Normandy battle and kept there by Hitler's "no withdrawal" orders until they collapsed and a large part of them were trapped. The fragments were incapable of further resistance, and their retreat (which was largely on foot) was soon outstripped by the British and American mechanized columns. More than 200,000 German troops were taken prisoner in France, and 1,200 German tanks had been destroyed in the fighting. When the Allies approached the German border at the beginning of September, after a sweeping drive from Normandy, there was no organized resistance to stop them from driving on into the heart of Germany.

Meanwhile, "Operation Dragoon" (formerly "Anvil") was launched on Aug. 15, 1944, when the U.S. 7th Army and the French 1st Army landed on the French Riviera, where there were only four German divisions to oppose them. While the Americans drove first into the Alps to take Grenoble, the French took Marseille on August 23 and then advanced eastward through France up the Rhône Valley, to be rejoined by the Americans north of Lyon early in September. Both armies then moved swiftly northeastward into Alsace.

In the north, however, some discord had arisen among the Allied commanders after the crossing of the Seine. Whereas Montgomery wanted to concentrate on a single thrust northeastward through Belgium into the heavily industrialized Ruhr Valley (an area vital to Germany's war effort), the U.S. generals argued for continuing to advance eastward through France on a broad front, in accordance with the pre-invasion plan. Eisenhower, by way of compromise, decided on August 23 that Montgomery's drive into Belgium should have the prior claim on resources until Antwerp should have been captured but that thereafter the pre-invasion plan should be resumed.

Consequently, Montgomery's 2nd Army began its advance on August 29, entered Brussels on September 3, took Antwerp, with its docks intact, on September 4, and went on, three days later, to force its way across the Albert Canal. The U.S. 1st Army, meanwhile, supporting Montgomery on the right, had taken Namur on the day of the capture of Antwerp and was nearing Aachen. Far to the south, however, Patton's U.S. 3rd Army, having raced forward to take Verdun on August 31, was already beginning to cross the Moselle River near Metz on September 5, with the obvious possibility of achieving a breakthrough into Germany's economically important Saarland. Eisenhower, therefore, could no longer devote a preponderance of supplies to Montgomery at Patton's expense.

Montgomery nevertheless attempted a thrust to cross the Rhine River at Arnhem, the British 1st Airborne Division being dropped ahead there to clear the way for the 2nd Army; but the Germans were just able to check the thrust, thus isolating the parachutists, many of whom were taken prisoner. By this time, indeed, the German defense was rapidly stiffening as the Allies approached the German frontiers: the U.S. 1st Army spent a month grinding down the defenses of Aachen, which fell at last on October 20 (the first city of prewar Germany to be captured by the western Allies); and the 1st Canadian Army, on the left of the British 2nd, did not clear the Schelde estuary west of Antwerp, including Walcheren Island, until early November. Likewise, Patton's 3rd Army was held up before Metz.

The Allies' amazing advance of 350 miles in a few weeks was thus brought to a halt. In early September the U.S. and British forces had had a combined superiority of 20 to 1 in tanks and 25 to 1 in aircraft over the Germans, but by November 1944 the Germans still held both the Ruhr Valley and the Saarland, after having been so near collapse in the west in early September that one or the other of those prizes could have easily been taken by the Allies. The root of the Allied armies' sluggishness in September was that none of their top planners had foreseen such a complete collapse of the Germans as occurred in August

The plot against Hitler [margin note]

Southern France invaded [margin note]

1944. They were therefore not prepared, mentally or materially, to exploit it by a rapid offensive into Germany itself. The Germans thus obtained time to build up their defending forces in the west, with serious consequences both for occupied Europe and the postwar political situation of the Continent.

The Eastern Front, June–December 1944. After a successful offensive against the Finns on the Karelian Isthmus had culminated in the capture of Viipuri (Vyborg) on June 20, 1944, the Red Army on June 23 began a major onslaught on the Germans' front in Belorussia. The attackers' right wing took the bastion town of Vitebsk (Vitebskaya) and then wheeled southward across the highway from Orsha to Minsk; their left wing, under General Konstantin Konstantinovich Rokossovsky, broke through just north of the Pripet Marshes and then drove forward for 150 miles in a week, severing the highway farther to the west, between Minsk and Warsaw. Minsk itself fell to the Red Army on July 3; and, though the Germans extricated a large part of their forces from the Soviet enveloping movement, the Soviet tanks raced ahead, bypassing any attempts to block their path, and were deep into Lithuania and northeastern Poland by mid-July. Then the Soviet forces south of the Pripet Marshes struck too, capturing Lwów and pushing across the San River. This increase of pressure on the Germans enabled Rokossovsky's mobile columns to thrust still farther westward: they reached the Vistula River, and one of them, on July 31, even penetrated the suburbs of Warsaw. The Polish underground in Warsaw thereupon rose in revolt against the Germans and briefly gained control of the city. But three SS armoured divisions arrived to suppress the revolt in Warsaw, and the Soviet Red Army stood idly by across the Vistula while the Germans crushed the insurrection. Although the Soviet halt outside Warsaw was a purposeful move, it is true that the unprecedented length and speed of the Red Army's advance—450 miles in five weeks—had overstrained the Soviet communications. The halt on the Vistula was to last six months.

On August 20, however, two Soviet thrusts were launched in another direction—against the German salient in Bessarabia. A new government came to power in Romania on August 23 and not only suspended hostilities against the U.S.S.R. but also, on August 25, declared war against Germany. This long-premeditated volte-face opened the way for three great wheeling movements by the Red Army's left wing through the vast spaces of southeastern and central Europe: southwestward across Bulgaria, where they met no opposition; westward up the Danube Valley and over the Yugoslav frontier; and northwestward through the Carpathians into Transylvania. The Germans could only try to hold the threatened centres of communication long enough for the withdrawal of their forces from Greece and from southern Yugoslavia. Belgrade fell to a concerted action by the Red Army and Tito's Partisan forces on Oct. 20, 1944; and a rapid drive from the Transylvanian sector into the Hungarian Plain brought Soviet forces up to the suburbs of Budapest on November 4. Budapest, however, was stubbornly defended: by the end of the year, it was enveloped but still holding out.

At the northern end of the Eastern Front, Finland had capitulated early in September, and the following weeks saw a series of scythelike strokes by the Red Army against the German forces remaining in Estonia, Latvia, and Lithuania. By mid-October the remnants of those forces were cornered in Courland, but the subsequent Soviet attempt to break through from Lithuania into East Prussia was repelled.

Air warfare, 1944. The Allies' strategic air offensive against Germany began to attain its maximum effectiveness in the opening months of 1944. Both the U.S. air forces concerned, namely, the 8th in England and the 15th in Italy, were increased in numbers and improved in technical proficiency. By the end of 1943 the 8th Bomber Command alone could mount attacks of 700 planes, and early in 1944 regular 1,000-bomber attacks became possible. Even more important was the arrival in Europe of effective long-range fighters, chief of which, the P-51 Mustang, was capable of operating at maximum bomber

range. The U.S. fighters could now get the better of the Luftwaffe in the air over Germany, so that whereas 9.1 percent of bombers going out had been lost and 45.6 percent damaged in October 1943, the corresponding figures were only 3.5 percent and 29.9 percent in February 1944, though in that very month a massive and very difficult attack at extreme range had been made on the German aircraft industry. Carl Spaatz, commanding general of the U.S. Strategic Air Forces in Europe, in May 1944 initiated an offensive against Germany's synthetic-oil production—an offensive that was to become more and more harmful to the German war effort after the loss of Romania's oil fields to the Soviet Union. Meanwhile, the Luftwaffe's resistance dwindled almost to nothing as its fighter plane production dropped and most of its remaining trained pilots died in aerial combat.

The RAF Bomber Command launched nearly 10,000 sorties in March 1944 and dropped some 27,500 tons of bombs, about 70 percent of this effort being concentrated on Germany; but in the following months its offensive was largely diverted to the intensive preparation and, later, to the support of the Allied landings in France. Nevertheless, it joined usefully in the U.S. offensive against German oil production, continued to play its part in the Battle of the Atlantic, and also assumed the task of bombing the launching ramps of the Germans' "V" missiles. By early 1945, the unending Allied bombing and strafing raids on bridges, roads, rail facilities, locomotives, and supply columns had paralyzed the German transportation system.

The "V" missiles, flying bombs and long-range rockets, were the new weapons on which Hitler had vainly been counting to reduce Great Britain to readiness for peace. His faith in them had indeed been a major motive for his insistence on holding the sites, in northernmost France, from which they were initially to be aimed at London. The V1 missiles were first launched on June 13, 1944, mostly from sites in the Pas-de-Calais; the V2 missiles were launched a few months later, on September 8, from sites in The Netherlands (after the Allies' occupation of the Pas-de-Calais on their way to Belgium). The V2 offensive was maintained until March 1945. | Germany's "V" weapons

Allied policy and strategy: Octagon (Quebec II) and Moscow, 1944. The progress of the Soviet armies toward central and southeastern Europe made it all the more urgent for the western Allies to come to terms with Stalin about the fate of the "liberated" countries of eastern Europe. London had already proposed to Moscow in May 1944 that Romania and Bulgaria should be zones for Soviet military operation, Yugoslavia and Greece—whose royalist governments in exile were under British protection—for British; and Roosevelt had approved this proposition in June.

The Soviet Union had in February 1944 sent a military mission to Tito's Communist Partisans in Yugoslavia (the Partisans had become the sole Yugoslavian recipients, since the Tehrān Conference, of western aid, though their royalist rivals, the Chetniks, were not publicly disavowed by Churchill until May 25). Along with this, a would-be government of Greece had been set up in March by the EAM (National Liberation Front), which was a Communist movement controlling a military organization, the ELAS (National Popular Liberation Army), in opposition to the EDES (Greek Democratic National Army), which was loyal to the British-backed government in exile. The Polish question, moreover, was still unresolved, and in July the Soviets established, at Lublin, a Committee of National Liberation independent of the London Poles. In Romania, despite the government's change of side in August, the Soviets proceeded to disband the Romanian Army; and early in September they declared war on Bulgaria, invaded that country, and sponsored a Communist revolution there.

With this background, Churchill and Roosevelt met again for their second Quebec Conference, code-named "Octagon," which lasted from September 11 to 16. The most important decision made at the conference was that Roosevelt and Churchill together approved the European Advisory Commission's scheme for the division of defeated Germany into U.S., British, and Soviet zones of | "Octagon" and the Moscow Conference

occupation (the southwest, the northwest, and the east, respectively) and also the radical plan elaborated by the U.S. secretary of the treasury, Henry Morgenthau, Jr., for turning Germany "into a country primarily agricultural and pastoral" without "war-making industries." The Morgenthau Plan, however, was subsequently revoked.

The next conference of the Allies was held in Moscow Oct. 9–20, 1944, between Churchill and Stalin, with U.S. ambassador W. Averell Harriman also present at most of their talks. Disagreement persisted over Poland. Stalin, however, consented readily to Churchill's provisional suggestion for zones of influence in southeastern Europe: the U.S.S.R. should be preponderant in Romania and in Bulgaria, the western powers in Greece, and western and Soviet influences should counterbalance one another evenly in Yugoslavia and in Hungary. The timing of the next western and Soviet offensives against Germany was also agreed, and some accord was reached about the scale of the eventual Soviet participation in the war against Japan.

The Philippines and Borneo, from September 1944. On July 27–28, 1944, Roosevelt had approved MacArthur's argument that the next objective in the Pacific theatre of the war should be the Philippine Archipelago (which was comparatively near to the already conquered New Guinea). The initial steps toward the Philippines were taken almost simultaneously, in mid-September 1944: MacArthur's forces from New Guinea seized Morotai, the northeasternmost isle of the Moluccas, which was on the direct route to Mindanao, southernmost landmass of the Philippines; and Nimitz' fleet from the east landed troops in the Palau Islands.

Already by mid-September the Americans had discovered that the Japanese forces were unexpectedly weak not only on Mindanao but also on Leyte, the smaller island north of the Surigao Strait. With this knowledge they decided to bypass Mindanao and to begin their invasion of the Philippines on Leyte. On Oct. 17–18, 1944, American forces seized offshore islets in Leyte Gulf, and on October 20 they landed four divisions on the east coast of Leyte.

The threat to Leyte was the signal for the Japanese to put into effect their recently formulated plan "Sho-Go" ("Operation Victory"), whereby the Allies' next attempts at invasion were to be countered by concerted air attacks. Though in the case of Leyte the Japanese Army and Navy air forces in the immediate theatre numbered only 212 planes, it was hoped that the dispatch of four carriers under Vice Admiral Ozawa, with 106 planes, southward from Japanese waters would lure the U.S. aircraft carriers away from Leyte Gulf and that the suicidal "kamikaze" tactics of the Japanese airmen would save the situation. (Kamikaze pilots deliberately crashed their bomb-armed planes into enemy ships.) At the same time, however, a Japanese naval force from Singapore was to sail to Brunei Bay and there split itself into two groups that would converge on Leyte Gulf from the north and from the southwest: the stronger group, under Vice Admiral Kurita Takeo, would enter the Pacific through the San Bernardino Strait between the Philippine islands of Samar and Luzon; the other, under Vice Admiral Nishimura Teiji, would pass through the Surigao Strait.

Kurita's fleet (five battleships, 12 cruisers, 15 destroyers) lost two of its heavy cruisers to U.S. submarine attack on October 23, when it was off Palawan; and one of the mightiest of Japan's battleships, the *Musashi*, was sunk by aerial attack the next day. On October 25, however, Kurita made his way unopposed through the San Bernardino Strait, since the commander of the U.S. 3rd Fleet, Admiral Halsey, had diverted his main strength toward the bait dangled by Ozawa farther to the north. Three groups of U.S. escort carriers, met by Kurita on his way toward Leyte Gulf, suffered heavy damage; but, meanwhile, Nishimura's fleet (two battleships, one heavy cruiser, four destroyers) had been detected on its way to the Surigao Strait and, on its entry into Leyte Gulf in the early hours of October 25, had been practically annihilated by the U.S. 7th Fleet. Kurita consequently turned back from his rendezvous in Leyte Gulf; and the Japanese defeat in the war's greatest naval confrontation was sealed by Ozawa's losses to Halsey: all of his four carriers, together with

The Battle of Leyte Gulf

a light cruiser and two destroyers. The Japanese Navy's "Sho-Go" as it transpired in the Battle of Leyte Gulf had not only failed to inflict serious damage on the Americans but had resulted in serious losses for the Japanese. These losses amounted to three battleships, one large aircraft carrier, three light carriers, six heavy cruisers, four light cruisers, and 11 destroyers, while the United States lost only one light carrier, two escort carriers, and three destroyers. The battle reduced the Japanese Navy to vestigial strength and cleared the way for the U.S. occupation of the Philippines.

Defeat in the gulf, however, did not prevent the Japanese from landing reinforcements on the west coast of Leyte. They put up so stubborn a resistance that the Americans themselves had to be reinforced before Ormoc fell on Dec. 10, 1944; it was not before December 25 that the Americans could claim control of all Leyte—though there was still some mopping up to be done. Altogether, the defense of Leyte cost the Japanese some 75,000 combatants killed or taken prisoner.

From Leyte the Americans proceeded first, on December 15, to the invasion of Mindoro, the largest of the islands immediately south of Luzon. Kamikaze counterattacks made this conquest more costly; and they were to be continued after the Americans had surprised the Japanese by landing, on Jan. 9, 1945, at Lingayen Gulf on the west coast of Luzon itself, the most important island of the Philippines. The local Japanese commander, Lieutenant General Yamashita Tomoyuki, with no hope of reinforcement, opted for tying the enemy forces down as long as possible by a static defense in three mountainous sectors—west, northwest, and east of the Central Plains behind Manila.

Manila itself was also strongly defended by the Japanese. One U.S. corps, however, was approaching it from Lingayen over the Central Plains; a second corps was landed at Subic Bay, at the northern end of the Bataan Peninsula, on Jan. 29, 1945, to make contact with the former corps at Dinalupihan a week later; and troops made an amphibious landing at Nasugbu, south of Manila Bay, on January 31. Manila was then invested, and during the siege the bay was cleared by the occupation of the southern tip of Bataan Peninsula on February 15 and by the reduction of Corregidor Island in the following fortnight. On March 3 Manila fell at last to the Americans.

The retaking of Manila

The Japanese resistance on Luzon continued in the mountains, and east of Manila it went on until mid-June 1945. Mindanao, meanwhile, was likewise being reduced. A U.S. division landed at Zamboanga, on the southwestern peninsula, on March 10, 1945, and a corps began the occupation of the core of the island on April 17.

The last phase of the U.S. campaign in the Philippines coincided with the opening of the reconquest of Borneo from the Japanese, chiefly by Australian forces. Tarakan Island, off the northeast coast, was invaded on May 1; Brunei on the northwest coast was invaded on June 10; and Balikpapan, on the east coast far to the south of Tarakan, was attacked on July 1. The subsequent collapse of the Japanese defenses around Balikpapan deprived Japan of the oil supplies of southern Borneo.

Burma and China, October 1944–May 1945. Chiang Kai-shek's demand for the recall of the talented but abrasive Stilwell was satisfied in October 1944, and some reorganization of the Allies' commands in Southeast Asia followed. While Lieutenant General Daniel Sultan took Stilwell's place, Major General A.C. Wedemeyer became commander of U.S. forces in the China theatre and Sir Oliver Leese commander of the land forces under Mountbatten.

On the northern wing of the Burma front, a three-pronged drive by NCAC forces southward from Myitkyina to the Irrawaddy River had been planned by Stilwell. Launched under Sultan, the triple drive was at first only partially successful: the right took Indaw and Katha early in December and effected a junction with Slim's British 14th Army, and the centre reached Shwegu, across the river; but the left, though it took Bhamo, was checked 60 miles west of Wan-t'ing. Sultan thereupon decided to push farther southward, both on the right against Kyaukme,

on the Burma Road northeast of Mandalay, and on the left against Wan-t'ing. Threatened with envelopment, the Japanese fell back from Wan-t'ing, which Sultan's troops promptly occupied. Convoys up the Burma Road from Wan-t'ing to K'un-ming were resumed on Jan. 18, 1945.

The Burma Road reopened

For central Burma, meanwhile, Slim had thought, after his victory at Imphāl, that he must immediately seize the crossings of the Chindwin River at Sittaung and at Kalewa and then advance southward against Mandalay itself. He did indeed effect the Chindwin crossings, but in mid-December 1944 he saw that the Japanese were in any case going to withdraw altogether to the left bank of the Irrawaddy. Thereupon, he changed his plan: his objective should rather be Meiktila, which lay east of the Irrawaddy and was a vital centre of Japanese communications between Mandalay and Rangoon to the south. To conceal his new intention, he allowed one of the corps already directed against Mandalay to continue its eastward advance, but the other corps was surreptitiously moved over a circuitous route of 300 miles southward to Pakokku, which lay south of the Chindwin-Irrawaddy confluence and northwest of Meiktila. While the crossing of the Irrawaddy by the former corps on both sides of Mandalay distracted the attention of the Japanese, the latter corps took Meiktila on March 3, 1945, and held it against fierce counterattacks. Mandalay fell 10 days later, and the whole area was under the 14th Army's control by the end of the month. When the action was over, two Japanese armies had lost one-third of their fighting strength.

It remained for Slim to capture the Burmese capital, Rangoon. Allied ground forces advanced on Rangoon along two routes from the north: one corps, having moved down the Sittang Valley east of the Irrawaddy, took Pegu; the other, moving down the river, took Prome (Pye). The monsoon, however, was imminent, and to forestall it a small combined operation was undertaken: parachute troops were dropped at Elephant Point, on the coast south of Rangoon, on May 1, 1945; and an Indian division, landing at Rangoon itself the next day, took the city without opposition, just when the monsoon rains were beginning to fall. The recapture of Burma was essentially complete with the taking of Rangoon.

Rangoon liberated

The German offensive in the west, winter 1944–45. Hitler still hoped to drive the Allies back and still adhered to his principle of concentrating on the war in the west. Late in 1944, therefore, he assembled on the Western Front all the manpower that had become available as a consequence of his second "total mobilization": a decree of October 18 had raised a *Volkssturm,* or "home guard," for the defense of the Third Reich, conscripting all able-bodied men between the ages of 16 and 60 years.

In mid-November all six Allied armies on the Western Front had launched a general offensive; but, though the French 1st Army and the U.S. 7th had reached the Rhine River in Alsace, there were only small gains on other sectors of the front. Meanwhile, the German defense was being continuously strengthened with hastily shifted reserves and with freshly raised forces, besides the troops that had managed to make their way back from France. The German buildup along the front was by now progressing faster than that of the Allies, despite Germany's great inferiority of material resources. In mid-December 1944 the Germans gave the Allied armies a shock by launching a sizable counteroffensive. The Germans amassed 24 divisions for the attack. Under the overall command of the reinstated Rundstedt, this attack was to be delivered through the wooded hill country of the Ardennes against the weakest sector of the U.S.-manned front, between Monschau (southwest of Aachen) and Echternach (northwest of Trier). While the 5th Panzer Army on the left, under the talented commander General Hasso von Manteuffel, with its own left flank covered by the German 7th Army, was to wheel northwestward after the breakthrough and to cross the Meuse River of Namur in a drive on Brussels, the 6th Panzer Army on the right, under SS General Sepp Dietrich, was to wheel more sharply northward against the Allies' important supply port of Antwerp. Thus, it was hoped, the British and Canadian forces at the northern end of the front could be cut off from their

supplies and crushed, while the U.S. forces to the south were held off by the German left.

The offensive was prepared with skill and secrecy and was launched on Dec. 16, 1944, at a time when mist and rain would minimize the effectiveness of counteraction from the air. The leading wedge of the attack by eight German armoured divisions along a 75-mile front took the Allies by surprise; and the 5th Panzer Army, which achieved the deeper penetration, reached points within 20 miles of the crossings of the Meuse River at Givet and at Dinant. U.S. detachments, however, stood firm, albeit outflanked, at Bastogne and at other bottlenecks in the Ardennes; and there followed what is popularly remembered as the Battle of the Bulge. By December 24 the German drive had narrowed but deepened, having penetrated about 65 miles into the Allied lines along a 20-mile front. But by this time the Allies had begun to respond. Montgomery, who had taken charge of the situation in the north, swung his reserves southward to forestall the Germans on the Meuse. Bradley, commanding the Allied forces south of the German wedge, sent his 3rd Army under Patton to the relief of Bastogne, which was accomplished on December 26. The weather cleared, and as many as 5,000 Allied aircraft began to bomb and strafe the German forces and their supply system. During Jan. 8–16, 1945, the German attackers were compelled to withdraw, lest the salient that they had driven into the Allied front be cut off in its turn. Though their abortive offensive inflicted much damage and upset the Allies' plans, the Germans spent too much of their strength on it and thereby forfeited whatever chance they had had of maintaining prolonged resistance later. The Germans sustained 120,000 casualties and the Americans sustained about 75,000 in the Battle of the Bulge.

The Battle of the Bulge

The Soviet advance to the Oder, January–February 1945. At the end of 1944 the Germans still held the western half of Poland, and their front was still 200 miles east of where it had been at the start of the war in 1939. The Germans had checked the Soviets' summer offensive and had established a firm line along the Narew and Vistula rivers southward to the Carpathians, and in October they repelled the Red Army's attempted thrust into East Prussia. Meanwhile, however, the Soviet left, moving up from the eastern Balkans, had been gradually pushing around through Hungary and Yugoslavia in a vast flanking movement; and the absorption of German forces in opposing this side-door approach detracted considerably from the Germans' capacity to maintain their main Eastern and Western fronts.

The Soviet high command was now ready to exploit the fundamental weaknesses of the German situation. Abundant supplies for their armies had been accumulated at the railheads. The mounting stream of American-supplied trucks had by this time enabled the Soviets to motorize a much larger proportion of their infantry brigades and thus, with the increasing production of their own tanks, to multiply the number of armoured and mobile corps for a successful breakthrough.

Before the end of December ominous reports were received by Guderian—who, in this desperately late period of the war, had been made chief of the German general staff. German Army intelligence reported that 225 Soviet infantry divisions and 22 armoured corps had been identified on the front between the Baltic and the Carpathians, assembled to attack. But when Guderian presented the report of these massive Soviet offensive preparations, Hitler refused to believe it, exclaiming: "It's the biggest imposture since Genghis Khan! Who is responsible for producing all this rubbish?"

If Hitler had been willing to stop the Ardennes counteroffensive in the west, troops could have been transferred to the Eastern Front; but he refused to do so. At the same time he refused Guderian's renewed request that the 30 German divisions now isolated in Courland (on the Baltic seacoast in Lithuania) should be evacuated by sea and brought back to reinforce the gateways into Germany. As a consequence, Guderian was left with a mobile reserve of only 12 armoured divisions to back up the 50 weak infantry divisions stretched out over the 700 miles of the main front.

The Soviet offensive opened on Jan. 12, 1945, when Konev's armies were launched against the German front in southern Poland, starting from their bridgehead over the Vistula River near Sandomierz. After it had pierced the German defense and produced a flanking menace to the central sector, Zhukov's armies in the centre of the front bounded forward from their bridgeheads nearer Warsaw. That same day, January 14, Rokossovsky's armies also joined in the offensive, striking from the Narew River north of Warsaw and breaking through the defenses covering this flank approach to East Prussia. The breach in the German front was now 200 miles wide.

On Jan. 17, 1945, Warsaw was captured by Zhukov, after it had been surrounded; and on January 19 his armoured spearheads drove into Łódź. That same day Konev's spearheads reached the Silesian frontier of prewar Germany. Thus, at the end of the first week the offensive had been carried 100 miles deep and was 400 miles wide—far too wide to be filled by such scanty reinforcements as were belatedly provided.

The crisis made Hitler renounce any idea of pursuing his offensive in the west; but, despite Guderian's advice, he switched the 6th Panzer Army not to Poland but to Hungary in an attempt to relieve Budapest. The Soviets could thus continue their advance through Poland for two more weeks. While Konev's spearheads crossed the Oder River in the vicinity of Breslau (Wrocław) and thus cut Silesia's important mineral resources off from Germany, Zhukov made a sweeping advance in the centre by driving forward from Warsaw, past Poznań, Bydgoszcz, and Toruń, to the frontiers of Brandenburg and of Pomerania. At the same time Rokossovsky pushed on, through Allenstein (Olsztyn), to the Gulf of Danzig, thus cutting off the 25 German divisions in East Prussia. To defend the yawning gap in the centre of the front, Hitler created a new army group and put Heinrich Himmler in command of it with a staff of favoured SS officers. Their fumbling helped to clear the path for Zhukov, whose mechanized forces by Jan. 31, 1945, were at Küstrin, on the lower Oder, only 40 miles from Berlin.

Zhukov's advance now came to a halt. Konev, however, could still make a northwesterly sweep down the left bank of the middle Oder, reaching Sommerfeld, 80 miles from Berlin, on February 13, and the Neisse River two days later. The Germans' defense benefited from being driven back to the straight and shortened line formed by the Oder and Neisse rivers. This front, extending from the Baltic coast to the Bohemian frontier, was less than 200 miles long. The menace of the Soviets' imminent approach to Berlin led Hitler to decide that most of his fresh drafts of troops must be sent to reinforce the Oder; the way was thus eased for the crossing of the Rhine River by the American and British armies.

On Feb. 13, 1945, the Soviets took Budapest, the defense of which had entailed the Germans' loss of Silesia.

Yalta.   Roosevelt's last meeting with Stalin and Churchill took place at Yalta, in the Crimea, Feb. 4–11, 1945. The conference is chiefly remembered for its treatment of the Polish problem: the western Allied leaders, abandoning their support of the Polish government in London, agreed that the Lublin committee—already recognized as the provisional government of Poland by the Soviet masters of the country—should be the nucleus of a provisional government of national unity, pending free elections. But while they also agreed that Poland should be compensated in the west for the eastern territories that the U.S.S.R. had seized in 1939, they declined to approve the Oder–Neisse line as a frontier between Poland and Germany, considering that it would put too many Germans under Polish rule. For the rest of "liberated Europe" the western Allied leaders obtained nothing more substantial from Stalin than a declaration prescribing support for "democratic elements" and "free elections" to produce "governments responsive to the will of the people."

For Germany the conference affirmed the project for dividing the country into occupation zones, with the difference that the U.S. zone was to be reduced in order to provide a fourth zone, for the French to occupy. Roosevelt and Churchill, however, had already discarded the

The Soviet drive into Germany

Morgenthau Plan for the postwar treatment of Germany; and Yalta found no comprehensive formula to replace it. The three leaders simply pledged themselves to furnish the defeated Germans with the necessities for survival; to "eliminate or control" all German industry that could be used for armaments; to bring major war criminals to trial; and to set up a commission in Moscow for the purpose of determining what reparation Germany should pay.

The German collapse, spring 1945.   Before their ground forces were ready for the final assault on Germany, the western Allies intensified their aerial bombardment. This offensive culminated in a series of five attacks on Dresden, launched by the RAF with 800 aircraft in the night of Feb. 13–14, 1945, and continued by the U.S. 8th Air Force with 400 aircraft in daylight on February 14, with 200 on February 15, with 400 again on March 2, and, finally, with 572 on April 17. The motive of these raids was allegedly to promote the Soviet advance by destroying a centre of communications important to the German defense of the Eastern Front; but, in fact, the raids achieved nothing to help the Red Army militarily and succeeded in obliterating the greater part of one of the most beautiful cities of Europe and in killing at least 35,000 people and perhaps 135,000.

The destruction of Dresden

The main strength of the ground forces being built up meanwhile for the crossing of the Rhine was allotted to Montgomery's armies on the northern sector of the front. Meanwhile, some of the U.S. generals sought to demonstrate the abilities of their own less generously supplied forces. Thus, Patton's 3rd Army reached the Rhine at Coblenz (Koblenz) early in March, and, farther downstream, General Courtney H. Hodges' 1st Army seized the bridge over the Rhine at Remagen south of Bonn and actually crossed the river, while, still farther downstream, Lieutenant General William H. Simpson's 9th Army reached the Rhine near Düsseldorf. All three armies were ordered to mark time until Montgomery's grand assault was ready; but, meanwhile, they cleared the west bank of the river, and, eventually, in the night of March 22–23, the 3rd Army crossed the Rhine at Oppenheim, between Mainz and Mannheim, almost unopposed.

At last, in the night of March 23–24, Montgomery's attack by 25 divisions was launched across a stretch—30 miles long—of the Rhine near Wesel after a stupendous bombardment by more than 3,000 guns and waves of attacks by bombers. Resistance was generally slight; but Montgomery would not sanction a further advance until his bridgeheads were consolidated into a salient 20 miles deep. Then the Canadian 1st Army, on the left, drove ahead through The Netherlands, the British 2nd went northeastward to Lübeck and to Wismar on the Baltic, and the U.S. armies swept forward across Germany, fanning out to reach an arc that stretched from Magdeburg (9th Army) through Leipzig (1st) to the borders of Czechoslovakia (3rd) and of Austria (7th and French 1st).

Guderian had tried to shift Germany's forces eastward to hold the Red Army off; but Hitler, despite his anxiety for Berlin, still wished to commit the 11th and 12th armies—formed from his last reserves—to driving the western Allies back over the Rhine and, on March 28, replaced Guderian with General Hans Krebs as chief of the general staff.

The dominant desire of the Germans now, both troops and civilians, was to see the British and American armies sweep eastward as rapidly as possible to reach Berlin and occupy as much of the country as possible before the Soviets overcame the Oder line. Few of them were inclined to assist Hitler's purpose of obstruction by self-destruction. On March 19 (the eve of the Rhine crossing), Hitler had issued an order declaring that "the battle should be conducted without consideration for our own population." His regional commissioners were instructed to destroy "all industrial plants, all the main electricity works, waterworks, gas works" together with "all food and clothing stores" in order to create "a desert" in the Allies' path. When his minister of war production, Albert Speer, protested against this drastic order, Hitler retorted: "If the war is lost, the German nation will also perish. So there is no need to consider what the people require for continued existence." Appalled at such callousness, Speer was shaken

out of his loyalty to Hitler: he went behind Hitler's back to the army and industrial chiefs and persuaded them, without much difficulty, to evade executing Hitler's decree. The Americans and the British, driving eastward from the Rhine, met little opposition and reached the Elbe River 60 miles from Berlin, on April 11. There they halted.

On the Eastern Front, Zhukov enlarged his bridgehead across the Oder early in March. On their far left the Soviets reached Vienna on April 6; and on the right they took Königsberg on April 9. Then, on April 16, Zhukov resumed the offensive in conjunction with Konev, who forced the crossings of the Neisse; this time the Soviets burst out of their bridgeheads, and within a week they were driving into the suburbs of Berlin. Hitler chose to stay in his threatened capital, counting on some miracle to bring salvation and clutching at such straws as the news of the death of Roosevelt on April 12. By April 25 the armies of Zhukov and Konev had completely encircled Berlin, and on the same day they linked up with the Americans on the Elbe River.

Isolated and reduced to despair, Hitler married his mistress, Eva Braun, during the night of April 28–29, and on April 30 he committed suicide with her in the ruins of the Chancellery, as the advancing Soviet troops were less than a half mile from his bunker complex; their bodies were hurriedly cremated in the garden. The "strategy" of Hitler's successor, Dönitz, was one of capitulation and of saving as many as possible of the westward-fleeing civilians and of his German troops from Soviet hands. During the interval of surrender, 1,800,000 German troops (55 percent of the Army of the East) were transferred into the British–U.S. area of control.

On the Italian front, the Allied armies had long been frustrated by the depletion of their forces for the sake of other enterprises; but early in 1945 four German divisions were transferred from Kesselring's command to the Western Front, and in April the thin German defenses in Italy were broken by an Allied attack. A surrender document that had been signed on April 29 (while Hitler was still alive) finally brought the fighting to a conclusion on May 2.

The surrender of the German forces in northwestern Europe was signed at Montgomery's headquarters on Lüneburg Heath on May 4; and a further document, covering all the German forces, was signed with more ceremony at Eisenhower's headquarters at Reims, in the presence of Soviet as well as U.S., British, and French delegations. At midnight on May 8, 1945, the war in Europe was officially over.

Potsdam. The last inter-Allied conference of World War II, code-named "Terminal," was held at the suburb of Potsdam, outside ruined Berlin, from July 17 to Aug. 2, 1945. It was attended by the Soviet, U.S., and British heads of government and foreign ministers: respectively, Stalin and Molotov; President Harry S. Truman (Roosevelt's successor) and James F. Byrnes; and Churchill and Eden, the last-named pair being replaced by Clement Attlee and Ernest Bevin after Great Britain's change of government following a general election.

Operations against Japan were discussed, and the successful testing of an atomic bomb in the United States was divulged to Stalin. Pending the Soviet entry into the war against Japan, a declaration was issued on July 26 calling on Japan to surrender unconditionally and forecasting the territorial spoliation of the empire and the military occupation of Japan proper as well as the prosecution of war criminals, yet still promising that the Japanese people would not be enslaved or the nation destroyed.

Time was spent discussing the peace settlement and its procedure. Stalin induced Truman and Attlee to consent provisionally to the Soviet Union's demands that it should take one-third of Germany's naval and merchant fleet; have the right to exact reparations from its occupied zones of Germany and of Austria and also from Finland, Hungary, Romania, and even Bulgaria; and should furthermore receive a percentage of reparation from the western-occupied zones. The total amounts of all these exactions were, however, to be determined at a later date.

There was a profound disagreement at the conference about the Balkan areas occupied by the Red Army in which representatives of the western powers were allowed little say, and about the area east of the Oder–Neisse line, all of which the Soviets had arbitrarily put under Polish administration. The western statesmen protested at these lone-handed arrangements but perforce accepted them.

The end of the Japanese war, February–September 1945. While the campaign for the Philippines was still in progress, U.S. forces were making great steps in the direct advance toward their final objective, the Japanese homeland. Aerial bombardment was, of course, the prerequisite of the projected invasion of Japan—which was to begin, it was imagined, with landings on Kyushu, the southernmost of the major Japanese islands.

Iwo Jima and the bombing of Tokyo. With U.S. forces firmly established in the Mariana Islands, the steady long-range bombing of Japan by B-29s under the command of General Curtis E. LeMay continued throughout the closing months of 1944 and into 1945. But it was still 1,500 miles from Saipan to Tokyo, a long flight even for the B-29s. Strategic planners therefore fixed their attention on the little volcanic island of Iwo Jima in the Bonin Islands, which lay about halfway between the Marianas and Japan. If Iwo Jima could be eliminated as a Japanese base, the island could then be immensely valuable as a base for U.S. fighter planes defending the big bombers.

The Japanese were determined to hold Iwo Jima. As they had done on other Pacific islands, they had created underground defenses there, making the best possible use of natural caves and the rough, rocky terrain. The number of Japanese defenders on the island, under command of Lieutenant General Kuribayashi Tadamichi, was more than 20,000.

Day after day before the actual landing the island was subjected to intense bombardment by naval guns, by rockets, and by air strikes using napalm bombs. But the results fell far short of expectations. The Japanese were so well protected that no amount of conventional bombing or shelling could knock them out. U.S. Marines landed on Iwo Jima on Feb. 19, 1945, and encountered an obstinate resistance. Meanwhile, kamikaze counterattacks from the air sank the light carrier *Bismarck Sea* and damaged other ships; and, though the U.S. flag was planted on Mount Suribachi on February 23, the isle was not finally secured until March 16. Iwo Jima had cost the lives of 6,000 Marines, as well as the lives of nearly all the Japanese defenders; but in the next five months more than 2,000 B-29 bombers were able to land on it.

Meanwhile, a new tactic had been found for the bombing of Japan from bases in the Marianas. Instead of high-altitude strikes in daylight, which had failed to do much damage to the industrial centres attacked, low-level strikes at night, using napalm firebombs, were tried, with startling success. The first, in the night of March 9–10, 1945, against Tokyo, destroyed about 25 percent of the city's buildings (most of them flimsily built of wood and plaster), killed more than 80,000 people, and made 1,000,000 homeless. This result indicated that Japan might be defeated without a massive invasion by ground troops, and so similar bombing raids on such major cities as Nagoya, Ōsaka, Kōbe, Yokohama, and Toyama followed. Japan literally was being bombed out of the war.

Okinawa. Plans for invasion, however, were not immediately discarded. Okinawa, largest of the Ryukyu Islands strung out northeastward from Taiwan, had been regarded as the last stepping-stone to be taken toward Kyushu, which was only 350 miles away from it. It had therefore been subjected to a series of air raids from October 1944, culminating in March 1945 in an attack that destroyed hundreds of Japanese planes; but there were still at least 75,000 Japanese troops on the island, commanded by Lieutenant General Ushijima Mitsuru. The invasion of Okinawa was, in fact, to be the largest amphibious operation mounted by the Americans in the Pacific war.

Under the overall command of Nimitz, with Admiral Raymond Spruance in charge of the actual landings and with Lieutenant General Simon Bolivar Buckner commanding the ground forces, the operation began with the occupation of the Kerama Islets, 15 miles west of Okinawa, on March 26, 1945. Five days later a landing was made on

[margin notes:]
Hitler's suicide and the surrender of the Germans

Low-level incendiary bombing by night

Keise-Jima, whence artillery fire could be brought to bear on Okinawa itself. Then, on April 1, some 60,000 U.S. troops landed on the central stretch of Okinawa's west coast, seizing two nearby airfields and advancing to cut the island's narrow waist. Koiso's government in Tokyo resigned on April 5, and the U.S.S.R. on the same day refused to renew its treaty of nonaggression with Japan.

The first major counterattack on Okinawa by the Japanese, begun on April 6, involved not only 355 kamikaze air raids but also the *Yamato,* the greatest battleship in the world (72,000 tons, with nine 18.1-inch [460-millimetre] guns), which was sent out on a suicidal mission with only enough fuel for the single outward voyage and without sufficient air cover. The Japanese hoped the *Yamato* might finish off the Allied fleet after the latter had been weakened by kamikaze attacks. In the event, the *Yamato* was hit repeatedly by bombs and torpedoes and was sunk on April 7. Equally suicidal was a new Japanese weapon, *baka,* which claimed its first victim, the U.S. destroyer *Abele,* off Okinawa on April 12. *Baka* was a rocket-powered glider crammed with explosives which was towed into range by a bomber and was then released to be guided by its solitary pilot into the chosen target for their mutual destruction.

The U.S. ground forces invading Okinawa met little opposition on the beaches because Ushijima had decided to offer his main resistance inland, out of range of the enemy's naval guns. The southern half of the island this resistance was bitterest: it lasted until June 21, and Ushijima killed himself the next day. The campaign for Okinawa was ended officially on July 2. For U.S. troops it had been the longest and bloodiest Pacific campaign since Guadalcanal in 1942. Taking the island had cost the Americans 12,000 dead and 36,000 wounded, with 34 ships sunk and 368 damaged, and the Japanese losses exceeded 100,000 dead.

On April 3, 1945, two days after the first landing on Okinawa, the U.S. command in the Pacific was reorganized: MacArthur was henceforth to be in command of all army units and also in operational control of the U.S. Marines for the invasion of Japan; Nimitz was placed in command of all navy units.

Hiroshima and Nagasaki. Throughout July 1945 the Japanese mainlands, from the latitude of Tokyo on Honshu northward to the coast of Hokkaido, were bombed just as if an invasion was about to be launched. In fact, something far more sinister was in hand, as the Americans were telling Stalin at Potsdam.

In 1939 physicists in the United States had learned of experiments in Germany demonstrating the possibility of nuclear fission and had understood that the potential energy might be released in an explosive weapon of unprecedented power. On Aug. 2, 1939, Albert Einstein had warned Roosevelt of the danger of Nazi Germany's forestalling other states in the development of an atomic bomb. Eventually, the U.S. Office of Scientific Research and Development was created in June 1941 and given joint responsibility with the war department in the Manhattan Project to develop a nuclear bomb. After four years of intensive and ever-mounting research and development efforts, an atomic device was set off on July 16, 1945, in a desert area at Alamogordo, N.M., generating an explosive power equivalent to that of more than 15,000 tons of TNT. Thus the atomic bomb was born. Truman, the new U.S. president, calculated that this monstrous weapon might be used to defeat Japan in a way less costly of U.S. lives than a conventional invasion of the Japanese homeland. Japan's unsatisfactory response to the Allies' Potsdam Declaration decided the matter. On Aug. 6, 1945, an atomic bomb carried from Tinian Island in the Marianas in a specially equipped B-29 was dropped on Hiroshima, at the southern end of Honshu: the combined heat and blast pulverized everything in the explosion's immediate vicinity, generated spontaneous fires that burned almost 4.4 square miles completely out, and killed between 70,-000 and 80,000 people, besides injuring more than 70,000 others. A second bomb, dropped on Nagasaki on August 9, killed between 35,000 and 40,000 people, injured a like number, and devastated 1.8 square miles.

The use of the atomic bomb

The Japanese surrender. News of Hiroshima's destruction was only slowly understood in Tokyo. Many members of the Japanese government did not appreciate the power of the new Allied weapon until after the Nagasaki attack. Meanwhile, on August 8, the U.S.S.R. had declared war against Japan. The combination of these developments tipped the scales within the government in favour of a group that had, since the spring, been advocating a negotiated peace. On August 10 the Japanese government issued a statement agreeing to accept the surrender terms of the Potsdam Declaration on the understanding that the emperor's position as a sovereign ruler would not be prejudiced. In their reply the Allies granted Japan's request that the emperor's sovereign status be maintained, subject only to their supreme commander's directives. Japan accepted this proviso on August 14, and the emperor Hirohito urged his people to accept the decision to surrender. It was a bitter pill to swallow, though, and every effort was made to persuade the Japanese to accept the defeat that they had come to regard as unthinkable. Even princes of the Japanese Imperial house were dispatched to deliver the Emperor's message in person to distant Japanese Army forces in China and in Korea, hoping thus to mitigate the shock. A clique of diehards nevertheless attempted to assassinate the new prime minister, Admiral Suzuki Kantarō; but by September 2, when the formal surrender ceremonies took place, the way had been smoothed.

Truman designated MacArthur as the Allied powers' supreme commander to accept Japan's formal surrender, which was solemnized aboard the U.S. flagship *Missouri* in Tokyo Bay: the Japanese foreign minister, Shigemitsu Mamoru, signed the document first, on behalf of the Emperor and his government. He was followed by General Umezu Yoshijiro on behalf of the Imperial General Headquarters. The document was then signed by MacArthur, Nimitz, and representatives of the other Allied powers. Japan concluded a separate surrender ceremony with China in Nanking on Sept. 9, 1945. With this last formal surrender, World War II came to an end.

COSTS OF THE WAR

Killed, wounded, prisoners, or missing. The statistics on World War II casualties are inexact. Only for the United States and the British Commonwealth can official figures showing killed, wounded, prisoners or missing for the armed forces be cited with any degree of assurance. For most other nations, only estimates of varying reliability exist. Statistical accounting broke down in both Allied and Axis nations when whole armies were surrendered or dispersed. Guerrilla warfare, changes in international boundaries, and mass shifts in population vastly complicated postwar efforts to arrive at accurate figures even for the total dead from all causes.

Civilian deaths from land battles, aerial bombardment, political and racial executions, war-induced disease and famine, and the sinking of ships probably exceeded battle casualties. These civilian deaths are even more difficult to determine, yet they must be counted in any comparative evaluation of national losses. There are no reliable figures for the casualties of the Soviet Union and China, the two countries in which casualties were undoubtedly greatest. Mainly for this reason, estimates of total dead in World War II vary anywhere from 35,000,000 to 60,000,000—a statistical difference of no small import. Few have ventured even to try to calculate the total number of persons who were wounded or permanently disabled.

However inexact many of the figures, their main import is clear. The heaviest proportionate human losses occurred in eastern Europe where Poland lost perhaps 20 percent of its prewar population, Yugoslavia and the Soviet Union around 10 percent. German losses, of which the greater proportion occurred on the Eastern Front, were only slightly less severe. The nations of western Europe, however great their suffering from occupation, escaped with manpower losses that were hardly comparable with those of World War I. In East Asia, the victims of famine and pestilence in China are to be numbered in the millions, in addition to other millions of both soldiers and civilians who perished in battle and bombardment.

Table 7: World War II Casualties

*Figures for deaths, insofar as possible, exclude those who died of natural causes or were suicides.   †As far as possible the figures in this column exclude those who died in captivity.   ‡Figures for all Commonwealth nations include those still missing in 1946, some of whom may be presumed dead.   §This figure comprises 60,595 killed in aerial bombardment, 30,248 in the merchant marine service, 624 in women's auxiliary services, and 1,206 in the Home Guard.   ‖ The figures for China comprise casualties of the Chinese Nationalist forces during 1937–45, as reported in 1946, and do not include figures for local armies and Communists. Estimates of 2,200,000 military dead and 22,000,000 civilian deaths appear in some compilations but are of doubtful accuracy.   ¶Czech military figures include only those who fought on the Allied side, not Sudeten Germans and others who served in the German Army.   ⁹Includes merchant marine personnel who served with Allies.   δFrench military casualties include those dead from all causes in the campaign of 1939–40, those of Free French, of rearmed French units that fought with Allies during 1942–45, and of French units that fought with Axis forces in Syria and North Africa during 1941–42 (1,200 dead).   These figures released in 1946 are possibly too high. Merchant seamen are included with military dead.   *Military figures drawn from statement released by Polish government in 1946 and include casualties in the campaign of 1939, those of the underground, of Polish forces serving with British and Soviet armies, and those incurred in the Warsaw uprising. Civilian casualty figures, which include 3,200,000 Jews, are based on this statement as modified by the calculations of population experts.   △Military figures include those of Army Ground and Air Forces, and those of the Navy, Marines, and Coast Guard. There were an additional 115,187 deaths of U.S. servicemen from non-battle causes. Civilians listed in 1946 as dead or missing include 5,638 of the merchant marine service.   +Available estimates of Soviet casualties vary widely. A Soviet officer who served with the high command in Berlin and left the Soviet service in 1949 placed total military losses at 13,600,000—8,500,000 dead or missing in battle; 2,600,000 dead in prison camps; 2,500,000 died of wounds—and estimated civilian casualties at 7,000,000. These figures have been widely accepted in Germany, but most U.S. compilations, based on Soviet announcements, list 6,000,000 to 7,500,000 battle deaths. Calculations made on the basis of population distribution by age and sex in the 1959 U.S.S.R. census give some credence to the higher figures, for they seem to indicate losses of from 15,000,000 to 20,000,000 males of military age in World War II. The figures used here are a compromise estimate, not intended to obscure the fact that Soviet casualties are, in reality, unknown in the West.   ⊗Estimates based on fragmentary data.   **Military estimates include men from outside Germany who served with the German armed forces and are based on the assumption that about 1,000,000 of the 1,250,000 men still listed as missing in Soviet territory in 1955 were dead. In addition, perhaps 250,000 military personnel died of natural causes, committed suicide, or were executed. Civilian figures are for Germany and Austria only, and they do not include an estimated 2,384,000 German deaths during 1944–46 resulting from Soviet invasion and forced transfers of population in the eastern provinces given to Poland after the war.   ††Figures for dead include those listed as still missing in compilation made by the Italian government in 1952 (131,419 military personnel and 3,651 civilians), but not 49,144 military deaths from natural causes or suicide. Known dead from enemy action amounted to 110,823, making a total of 159,957 military deaths from all causes if the missing are not included. Of this number, 92,767 occurred before the 1943 Armistice, 67,190 afterward.   ‡‡Based on an estimate of 1,600,000 total military deaths on the assumption that about half of those listed as missing in Soviet territory in 1949 were dead. About 300,000 of these probably resulted from causes not related to battle.

Table 7 contains what appear to be the best available statistics on armed forces casualties of all types resulting from battle, of civilian deaths from war-related causes, and estimated total deaths in each of the major nations involved in World War II. Figures rounded to thousands (and this device has been employed in all cases for total deaths) are estimates of varying reliability while omissions in any category indicate that any estimate would be the wildest of conjectures. Estimated casualties of resistance movements have been included in military figures, other victims of Nazi persecution in the civilian ones. In the latter category fall about 5,700,000 Jews, more than half of them from Poland, who died in Nazi concentration and death camps.

Human and material cost. There can be no real statistical measurement of the human and material cost of World War II. The money cost to governments involved has been estimated at more than $1,000,000,000,000 but this

figure cannot represent the human misery, deprivation, and suffering, the dislocation of peoples and of economic life, or the sheer physical destruction of property that the war involved.

Europe. The Nazi overlords of occupied Europe drained their conquered territories of resources to feed the German war machine. Industry and agriculture in France, Belgium, The Netherlands, Denmark, and Norway were forced to produce to meet German needs with a resulting deprivation of their own peoples. Italy, though at first a German ally, fared no better. The resources of the occupied territories in eastern Europe were even more ruthlessly exploited. Millions of able-bodied men and women were drained away to perform forced labour in German factories and on German farms. The whole system of German economic exploitation was enforced by cruel and brutal methods, and the guerrilla resistance it aroused was destructive in itself and provoked German reprisals that were even more

destructive, particularly in Poland, Yugoslavia, and the occupied portions of the Soviet Union.

Great Britain, which escaped the ravages of occupation, suffered heavily from the German aerial blitz of 1940–41 and later from V-bombs and rockets. On the other side, German cities were leveled by Allied bombers, and in the final invasion of Germany from both east and west there was much retaliatory devastation, destruction, and pillage.

The destruction of physical plant was immense and far exceeded that of World War I, when it was largely confined to battle areas. France estimated the total cost at an amount equivalent to three times the total French annual national income. Belgium and The Netherlands suffered damage roughly in similar proportions to their resources. In Great Britain about 30 percent of the homes were destroyed or damaged; in France, Belgium, and The Netherlands about 20 percent. Agriculture in all the occupied countries suffered heavily from the destruction of facilities and farm animals, the lack of machinery and fertilizers, and the drain on manpower. Internal transport systems were completely disrupted by the destruction or confiscation of rail cars, locomotives, and barges, and the bombing of bridges and key rail centres. By 1945 the economies of the continental nations of western Europe were in a state of virtually complete paralysis.

In eastern Europe the devastation was even worse. Poland reported 30 percent of its buildings destroyed, as well as 60 percent of its schools, scientific institutions, and public administration facilities, 30–35 percent of its agricultural property, and 32 percent of its mines, electrical power, and industries. Yugoslavia reported 20.7 percent of its dwellings destroyed. In the battlegrounds of the western portion of the Soviet Union, the destruction was even more complete. In Germany itself, the U.S. Strategic Bombing Survey found that in 49 of the largest cities, 39 percent of the dwelling units were destroyed or seriously damaged. Central business districts had generally been reduced to rubble, leaving only suburban rings standing around a destroyed core.

Millions throughout Europe were rendered homeless. There were an estimated 21,000,000 refugees, more than half of them "displaced persons" who had been deported from their homelands to perform forced labour. Other millions who had remained at home were physically exhausted by five years of strain, suffering, and undernourishment. The roads of Europe were swamped by refugees all through 1945 and into 1946 as more than 5,000,000 Soviet prisoners of war and forced labourers returned eastward to their homeland and more than 8,000,000 Germans fled or were evacuated westward out of the Soviet-occupied portions of Germany. Millions of other persons of almost every European nationality also returned to their own countries or emigrated to new homes in other lands.

The Far East. The devastation of World War II in China was inflicted on a country that was already suffering from the economic ills of overpopulation, underdevelopment, and a half-century of war, political disunity, and unrest. The territory occupied by Japanese forces was roughly equivalent to that occupied by the Axis in Europe and the period of occupation was longer. That area of China unoccupied by the Japanese was virtually cut off from the outside world after the Japanese conquest of Burma in early 1942, and its economy continually tottered on the brink of collapse. In both areas, famines, epidemics, and civil unrest were recurrent, much farmland was flooded, and millions of refugees fled their homes, some several times. Cities, towns, and villages were laid waste by aerial bombardment and marching armies. The transportation system, poor to begin with, was thoroughly disrupted. Most of the limited number of hospitals and health institutions in China were destroyed or lost.

In India famine was recurrent, and the Indian economy was severely strained to support the burden the Allied military authorities placed upon it. The Philippines suffered from three years of Japanese occupation and exploitation and from the destruction wrought in the reconquest of the islands by the Americans in 1944–45. The harbour at Manila was wrecked by the retreating Japanese, and many portions of the city were demolished by bombardment.

In Japan the U.S. Strategic Bombing Survey found the damage to urban centres comparable to that in Germany. In the aggregate, 40 percent of the built-up areas of 66 Japanese cities was destroyed, and approximately 30 percent of the entire urban population of Japan lost their homes and many of their possessions. Hiroshima and Nagasaki suffered the peculiar and lasting damage done by atomic explosion and radiation.

BIBLIOGRAPHY

World War I: DWIGHT E. LEE (ed.), *The Outbreak of the First World War: Causes and Responsibilities,* 4th ed. (1975), is a good introduction to the debate on the origins of the war. A more detailed account is provided in LUIGI ALBERTINI, *The Origins of the War of 1914,* 3 vol. (1952–57, reprinted 1980; originally published in Italian, 1942–43). A comprehensive general account of the war is BERNADOTTE E. SCHMITT and HAROLD C. VEDELER, *The World in the Crucible, 1914–1919* (1984). The standard military histories are BASIL HENRY LIDDELL HART, *A History of the World War, 1914–1918,* enl. ed. (1934, reprinted 1970); CYRIL B. FALLS, *The Great War* (1959); and MARC FERRO, *The Great War, 1914–1918* (1973, reprinted 1987; originally published in French, 1969). J.E. EDMONDS (comp.), *A Short History of World War I* (1951, reprinted 1968); and JOHN TERRAINE, *The Great War, 1914–1918: A Pictorial History* (1965, reprinted 1978), are useful introductions. Naval operations during the war are discussed in ARTHUR J. MARDER, *From the Dreadnought to Scapa Flow: The Royal Navy in the Fisher Era, 1904–1919,* 5 vol. (1961–70). International diplomacy during the war is treated in Z.A.B. ZEMAN, *The Gentlemen Negotiators* (1971; U.K. title, *A Diplomatic History of the First World War*).

World War II: Good summaries of the origins of World II include JOACHIM REMAK, *The Origins of the Second World War* (1976); and ANTHONY P. ADAMTHWAITE, *The Making of the Second World War* (1979). The origins of the war in the Pacific are treated in HERBERT FEIS, *The Road to Pearl Harbor: The Coming of the War Between the United States and Japan* (1950, reprinted 1971). The classic comprehensive military histories of the war are BASIL HENRY LIDDELL HART, *History of the Second World War* (1970, reissued 1979); J.F.C. FULLER, *The Second World War, 1939–45: A Strategical and Tactical History* (1948, reprinted 1968). An excellent overall history of Europe during the war is GORDON WRIGHT, *The Ordeal of Total War, 1939–45* (1968). The first phase of the war is treated in JOHN LUKACS, *The Last European War, 1939–1941* (1976). Treatments of the war in the Pacific include JOHN COSTELLO, *The Pacific War* (1981); AKIRA IRIYE, *Power and Culture: The Japanese-American War, 1941–1945* (1981); and WILLIAM CRAIG, *The Fall of Japan* (1967, reissued 1979). The standard naval histories are S.W. ROSKILL, *The War at Sea, 1939–1945,* 3 vol. in 4 (1954–61); and FRIEDRICH RUGE, *Der Seekrieg: The German Navy's Story, 1939–1945* (1957; U.K. title, *Sea Warfare, 1939–1945: A German Viewpoint;* originally published in German, 1954). Aerial operations are treated in R.J. OVERY, *The Air War, 1939–1945* (1980, reprinted 1987); and CHARLES WEBSTER and NOBLE FRANKLAND, *The Strategic Air Offensive Against Germany, 1939–1945,* 4 vol. (1961). Allied cooperation and diplomacy are treated in WILLIAM HARDY MCNEILL, *America, Britain, and Russia: Their Cooperation and Conflict, 1941–1946* (1953, reprinted 1970); HERBERT FEIS, *Churchill, Roosevelt, Stalin: The War They Waged and the Peace They Sought,* 2nd ed. (1967); and CHRISTOPHER THORNE, *Allies of a Kind: The United States, Britain, and the War Against Japan, 1941–1945* (1978). Decisions concerning the atomic bomb are outlined in HERBERT FEIS, *The Atomic Bomb and the End of World War II,* rev. ed. (1966); and MARTIN J. SHERWIN, *A World Destroyed: The Atomic Bomb and the Grand Alliance* (1975, reprinted 1987).

(J.R.-S./Ed.)

Writing

W riting is a form of human communication by means of a set of visible marks that are related, by convention, to some particular structural level of language. This definition highlights the fact that writing is in principle the representation of language rather than a direct representation of thought and the fact that spoken language has a number of levels of structure including sentences, words, syllables, and phonemes (the smallest units of speech used to distinguish one word or morpheme from another), any one of which a writing system can "map onto" or represent. Indeed, the history of writing is in part a matter of the discovery and representation of these structural levels of spoken language in the attempt to con-struct an efficient, general, and economical writing system capable of serving a range of socially valuable functions. Literacy is a matter of competence with a writing system and with the specialized functions that written language serves in a particular society.

This article treats the nature and origin of writing and its development in the world's major cultural regions. For discussion of the study of writing as a tool of historical research, see the sections *Epigraphy* and *Paleography* in HISTORY, THE STUDY OF.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* section 514.

The article is divided into the following sections:

The nature and origin of writing

WRITING AS A SYSTEM OF SIGNS

Languages are systems of symbols; writing is a system for symbolizing these symbols. A writing system may be defined as any conventional system of marks or signs that represents the utterances of a language. Writing renders language visible; while speech is ephemeral, writing is concrete and, by comparison, permanent. Both speaking and writing depend upon the underlying structures of language. Consequently, writing cannot ordinarily be read by someone not familiar with the linguistic structure underlying the oral form of the language. Yet writing is not merely the transcription of speech; writing frequently involves the use of special forms of language, such as those involved in literary and scientific works, which would not be produced orally. In any linguistic community the written language is a distinct and special dialect; usually there is more than one written dialect. Scholars account for these facts by suggesting that writing is related directly to language but not necessarily directly to speech. Consequently, spoken and written language may evolve somewhat distinctive forms and functions. These alternative relations may be depicted as follows:

writing
↑
speaking   writing   speaking
↑   ↖   ↗
language   language
It is the fact that writing is an expression of language rather than simply a way of transcribing speech that gives to writing, and hence to written language and to literacy, their special properties. As long as writing was seen merely as transcription, as it was by such pioneering linguists as Ferdinand de Saussure and Leonard Bloomfield earlier in the 20th century, its conceptual significance was seriously underestimated. Once writing was seen as providing a new medium for linguistic expression, its distinctness from speech was more clearly grasped. Scholars such as Milman Parry, Marshall McLuhan, Eric Havelock, Jack Goody, and Walter Ong were among the first to analyze the conceptual and social implications of using written as opposed to oral forms of communication.

Writing is merely one, albeit the most important, means of communicating by visible signs. Gestures—such as a raised hand for greeting or a wink for intimate agreement—are visible signs but they are not writing in that

they do not transcribe a linguistic form. Pictures, similarly, may represent events but do not represent language and hence are not a form of writing.

But the boundary between pictures and writing becomes less clear when pictures are used conventionally to convey particular meanings. In order to distinguish pictures from pictorial signs it is necessary to notice that language has two primary levels of structure that the French linguist André Martinet referred to as the "double articulation" of language: the meaning structures on one hand and the sound patterns on the other. Indeed, linguists define grammar as a system for mapping—establishing a system of relations between—sound and meaning. These levels of structure admit of several subdivisions, any one of which may be captured in a writing system. The basic unit of the meaning system is called a morpheme; one or more morphemes make up a word. Thus the word *boys* is composed of two morphemes, *boy* and plurality. Grammatically related words make up clauses that express larger units of meaning. Still larger units make up such discourse structures as propositions and less well-defined units of meaning such as prayers, stories, and poems.

The basic linguistic unit of the sound system is called a phoneme; it is a minimal, contrastive sound unit that distinguishes one utterance from another. Phonemes may be further analyzed in terms of a set of underlying distinctive features, features specifying the ways the sound is physically produced by passing breath through the throat and positioning the tongue and lips. Phonemes may be thought of as roughly equivalent to the sound segments known as consonants and vowels, and combinations of these segments make up syllables.

Writing systems can serve to represent any of these levels of sound or any of the levels of meaning, and, indeed, examples of all of these levels of structure have been exploited by some writing system or other. Writing systems, consequently, fall into two large general classes, those that are based on some aspect of meaning structure, such as a word or morpheme, and those that are based on some aspect of the sound system, such as the syllable or phoneme.

The earlier failure to recognize these levels of structure in language led some scholars to believe that some writing systems, so-called ideograms and pictograms, have been invented to express thought directly, bypassing language altogether. The 17th-century German philosopher Gottfried Leibniz set out to invent the perfect writing system, which would reflect systems of thought directly and thereby be readable by all human beings regardless of their mother tongues. We now know that such a scheme is impossible. Thought is too intimately related to language to be represented independently of it.

More recently there have been attempts to invent forms for communicating explicit messages without assuming a knowledge of any particular language. Such messages are communicated by means of pictorial signs. Thus the skirted human figure painted on the door to a toilet, the human figure with an upraised hand on the Pioneer spacecraft, the Amerindian drawing of a horse and rider upside down painted on a rock near a precipitous trail, and the visual patterns branded on range cattle are all attempts to use visual marks to communicate without making any appeal to the structure of any particular language.

However, such signs function only because they represent a high level of linguistic structure and because they function to express one of a highly restricted range of meanings already known to the reader and not because they express ideas or thoughts directly. The sign on the toilet door is an elliptical way of writing "women's washroom," just as the word "women" had been earlier. The plaque on the spacecraft can be read as a greeting only if the reader already knows how to express a human greeting symbolically. The inverted horse and rider expressed the message that horses and riders should avoid the trail. And the brand can be read as the name of the owner's ranch.

Such signs, therefore, express meanings, not thoughts, and they do so by representing meaning structures larger than can be expressed by a single word. They do so by expressing these meanings elliptically. Such signs are readable because the reader has to consider only a restricted

Some of the pictorial signs used at the 1984 Summer Olympic Games in Los Angeles, Calif.
By courtesy of the Comité International Olympique

set of possible meanings. While such pictorial signs could not be turned into a general writing system, they can be extremely efficient in serving a restricted set of functions.

The differences between such pictorial signs and other forms of writing are sufficiently great for some scholars to maintain that they are not legitimate types of writing. These differences are that pictorial signs are "motivated," that is, they visually suggest their meanings, and that they express whole propositions rather than single words. Other scholars would include such signs as a form of writing because they are a conventional means for expressing a particular linguistic meaning. Scholars agree that such a collection of signs could express only an extremely limited set of meanings.

A similar case is the ancient mosaic found at the entrance of a house in Pompeii, depicting a snarling dog on a chain and bearing the inscription *cave canem*, "beware of the dog." Even nonreaders could "read" the message; the picture is therefore a form of writing rather than of picture making. Such pictorial signs, including logotypes, trademarks, and brand names, are so common in modern urban societies that even very young children learn to read them. Such reading ability is described as "environmental" literacy, not associated with books and schooling.

Similarly, number systems have posed a problem for theorists because such symbols as the Arabic numerals *1, 2, 3*, etc., which are conventional across many languages, appear to express thought directly without any intermediary linguistic structure. However, it is more useful to think of these numerals as a particular orthography for representing the meaning structure of these numbers rather than their sound structures. The advantages of this orthography are that the orthography permits the user to carry out mathematical operations, such as carrying, borrowing, and the like, and that the same orthography may be assigned different phonological equivalents in different languages using the same number system. Thus, the numeral *2* is pronounced "two" in English, "deux" in French, "zwei" in German, and so on. Yet it represents not a thought but the word, a piece of language.

It is for these reasons that writing is said to be a system for transcribing language, not for representing thought directly. There are, of course, other systems for representing thought, including such activities as picture making, dance, and mime. These, however, are not representations of ordinary language; rather, they constitute what the American philosopher Nelson Goodman has called the "languages of art." These "languages," or semiotic systems, are systems of signs that are used for expressive and representational purposes. Each of these semiotic systems may, in turn, be represented by a notational system, a system for representing the semiotic system. Thus writing can be defined formally as a notational system for representing some level or levels of linguistic form.

Writing is so pervasive in everyday life that many people take it to be synonymous with language, and this confusion affects their understanding of language. The word *word* denotes ambiguously both the oral form and the written

form, and so people may confuse them. This occurs, for example, when people think that the sounds of language are made up of letters. Even Aristotle used the same word, *gramma*, to refer to the basic units of both speech and writing. Yet it is important to distinguish them. People may have competence in a language and yet know nothing about its written form. Similarly, writing is so fundamental to a modern, literate society that its significance has often been overestimated. Since the 18th century it has been common to identify literacy with civilization, indeed with all civil virtues. When European countries colonized other regions they thought it as important to teach "savages" to read and write as to convert them to Christianity. Modern anthropology has helped to revise what now seems a quaint set of priorities by showing not only that there are no genuinely primitive languages, but that differing languages mask no unbridgeable differences between human beings. All human beings are rational, speak a language of enormous expressive power, and live in, maintain, and transmit to their young a complex social and moral order.

Scholars of literature have in the past half-century amassed compelling evidence to demonstrate that a complex social order and a rich verbal culture can exist in nonliterate societies. The American scholar Milman Parry, writing in the 1920s, showed that the Homeric epic poems, long regarded as models of literary virtuosity, were in fact the product not of a literate but of an oral tradition. These poems were produced by bards who could not write and were delivered in recitals to audiences who could not read. Writing made possible the recording of these poems, not their composition. The hard and fast dividing line that put civilization and literacy on one side and savagery and irrationality on the other has been abandoned. To be unlettered is no longer confused with being ignorant.

Similarly, it was once generally held that all writing systems represent some stage in a progression toward the ideal writing system, the alphabet. The accepted view today is that all writing systems represent relatively optimal solutions to a large and unique set of constraints, including the structure of the language represented, the functions that the system serves, and the balance of advantages to the reader as opposed to the writer. Consequently, while there are important differences between speaking and writing and between various forms of writing, these differences vary in importance and in effect from language to language and from society to society.

THE FUNCTIONS OF WRITING

Given that literacy is not a prerequisite of rationality and civilization, it may be asked why writing systems were invented and why, when they were, they so completely displaced preexisting oral traditions. Many accounts have been given of the dramatic impact on an "oral" culture of the encounter with written text. Isak Dinesen, in her autobiographical *Out of Africa,* reported on the response of Kikuyu tribesmen to their first exposures to written texts: "I learned that the effect of a piece of news was many times magnified when it was imparted by writing. The messages that would have been received with doubt and scorn if they had been given by word of mouth were now taken as gospel truth."

Certainly writing has been observed to displace oral traditions. The American scholar Albert Lord wrote: "When writing is introduced and begins to be used for the same purposes as the oral narrative song, when it is employed for telling stories and is widespread enough to find an audience capable of reading, this audience seeks its entertainment and instruction in books rather than in the living songs of men, and the older art gradually disappears."

The adoption and use of writing systems depend primarily on their ability to preserve language and information through time and across space. But the use of a writing system for this purpose is shaped in part by the nature of the system and by the cultural practices in the society that has adopted it. These uses tend, therefore, to be local and specific and characteristic of a particular literate society.

The Canadian economist Harold Innis classified writing systems into two basic types: those that bind through time, exemplified by Egyptian hieroglyphics carved in stone and Akkadian cuneiform incised in clay; and those that bind across space, exemplified by the portable papyri used by the Romans. Writing used to store information for posterity may be considered to serve an archival function. Such writing may be used not only for constructing, accumulating, and preserving records of political, religious, scientific, and literary interest but also for the more mundane purpose of keeping trade accounts and records. Writing used to transmit information across space, as in letters, encyclicals, newspapers, and the like, may be considered to serve a communicative function. Writing used for purely private ends, to record notes, diaries, or other personal data, may be considered to serve a mnemonic function.

Almost any notational form may be used for mnemonic purposes, for only the person who "wrote" the message needs to be able to "read" it. The carved notches in a wooden counting stick or the pebbles in a counting sack corresponding to the number of cattle under the care of a cowherd are suitable aide-mémoire, since the writer knows what the notches or pebbles represent. But such a system could not be read by others; it would not be clear what the notches represented or even that they represented anything at all. For a writing system to be communicative, the signs must be conventionalized so that the meaning can be grasped by other readers. Such a system may be restricted to a small set of familiar messages that can be read by a limited circle of acquaintances. But for a writing system to serve an archival function it must be sufficiently conventionalized to permit decoding and interpretation by readers who may know nothing about the writer or his message. It is only with the development of explicit writing systems capable of representing the nuances conveyed in speech that writing can be used archivally or communicatively.

TYPES OF WRITING SYSTEMS

A writing system, technically referred to as a script or orthography, consists of a set of visible marks, forms, or structures called characters or graphs that are related to some structure in the linguistic system. Roughly speaking, if a character represents a meaningful unit, such as a morpheme or a word, the orthography is called a logographic writing system; if it represents a syllable, it is called a syllabic writing system; if a segment of a syllable, it is called a consonantal writing system or an unvocalized syllabary; and if a phoneme, it is called an alphabetic system. (A phonetic alphabet, such as the one devised by the International Phonetic Association, is one designed to transcribe any oral language into a common script.) Finally, a writing system based upon the articulatory features that underlie the phoneme, such as voicing and place of articulation, is called a featural writing system. These relations may be depicted as follows:

	linguistic structure	orthographic structure
meaning-based	text	—
	topic	—
	speech act	pictorial signs
	word	
	morpheme	logographic writing
sound-based	syllable	syllabic writing
	segment	consonantal writing
	phoneme	alphabetic writing
	phone	phonetic alphabet
	feature	featural writing system

While relatively pure examples of these different types of script are known, most writing systems that have been used for general purposes combine properties of more than one type.

Pictorial signs, such as the informational signs at a modern international airport (insofar as they can properly be called writing) can bear explicit linguistic messages only because of the extremely limited set of alternatives a reader is required to choose among. Such writing is of little use for conveying new messages since there is no convention for decoding them, and to that extent it cannot be a general writing system. It can, however, serve a limited set of purposes efficiently.

General writing systems all analyze the linguistic form

into constituents of meaning or sound. Chinese script is primarily a logographic script; each word or morpheme is represented by a single graph or character. Two words, even if they sound exactly the same, will be represented by entirely dissimilar characters. But as the number of distinguishable words in a language can run into the tens of thousands (written English has a recorded vocabulary of some 1,500,000 words), the number of logographic characters to be memorized is extremely large.

Syllabaries provide a distinctive symbol for each distinct syllable. A syllable is a unit of speech composed of a vowel sound or a combination of consonant and vowel sounds; the sounds *pa, pe, pi, po, pu* are different syllables and are easily distinguished in a word. The word *paper* has two syllables, *pa-per.* A syllabary such as Linear B, the Mycenaean script dating from about 1400 BC, would have a graph for each of those syllables. Syllables are the most readily distinguishable units of speech, and consequently, the earliest of the sound-based, or phonographic, writing systems are syllabic. The number of syllables in a language, while differing considerably from language to language, is always quite large, hence some hundreds of graphs may be required to make a functioning syllabary. Even then such writing systems are far from explicit, for any string of syllabic graphs may be read in a number of different ways. Reading of such a script would rely upon the reader's prior knowledge and ability to work from the context, along with some guesswork.

Consonantal writing systems, as the name implies, represent the consonantal value of a syllable while ignoring the vocalic element. Such a system, therefore, would represent the syllables *pa, pe, pi, po, pu* with a single character. Such scripts have graphs for consonant sounds but not for vowel sounds, with the result that a certain amount of guesswork is involved in determining which syllable is being represented. This ambiguity, however, should not be overemphasized. When a consonantal system is used to represent a language like English, in which vowels differentiate root morphemes (in English, *pat, pet, pit, pot, put* are all different morphemes), discarding the vowel results in a highly ambiguous written expression that can be understood only by a reader who already had a good idea of the content of the written message. But in Semitic languages, such as Hebrew and Arabic, the absence of characters representing vowels is much less serious, because in these languages vowel differences generally do not distinguish morphemes. Vowel differences mark inflections, such as tense and aspect, that, while of some importance to the representation of meaning, are both more readily recovered from context and less likely to change the overall meaning. The failure to notice the intimate relation between the morphophonemic structure of the language and the type of orthography has led some scholars to underestimate the efficiency of consonantal writing systems and, perhaps, to overestimate the centrality of the invention of the alphabet to the evolution of Western culture.

Alphabetic writing systems represent the phonological structure of the language. The smallest pronounceable segment of speech is a syllable, but a syllable may be analyzed into the distinctive underlying constituents called phonemes. The syllable *pa* is produced by passing a column of air through the vocal chords, an action that constitutes the vocalic element, bounded at the outset by sudden release of air through the lips, an action that constitutes the consonantal element. The achievement of the alphabet is to analyze the syllable into its underlying consonant and vowel constituents. The economy of representation comes from the fact that a large number of syllables can be generated from a small set of these constituents. An alphabet consisting of 21 consonants and five vowels can generate 105 simple consonant-and-vowel syllables and more than 2,000 consonant-vowel-consonant syllables. In short, an alphabet can represent a full range of phonological differences. It is a script particularly suited to representing a language in which morphological differences are marked in phonological differences; it is less useful for a language, such as Chinese, in which one syllable represents a large number of morphemes. For the Chinese language a logographic system is more efficient.

Featural writing systems exploit the fact that even phonemes are not the most fundamental units of analysis of speech. Rather, phonemes may be analyzed into sets of distinctive features. The phonemes represented by the letters *n* and *d* share the feature of the tongue touching the alveolar ridge above the upper teeth. Featural writing systems analyze the sounds described as consonants and vowels into their shared and distinguishing features. Examples of writing systems that employ at least in part a featural approach are the Korean Han'gŭl script created, according to tradition, by King Sejong in the 15th century and Pitman shorthand, a system for rapid writing invented in Britain in the 19th century. In Han'gŭl, vowels are represented by long horizontal or vertical lines distinguished by small marks, while consonants are represented by two-dimensional signs that suggest the articulations involved: pairs of lines representing lips together, tongue touching the roof of the mouth, an open throat, and the like. As the phonological system is organized around some dozen such features, an efficient script can be constructed out of 24 basic graphs. In addition, such a script makes syllables visually discriminable by organizing them into blocks to facilitate rapid reading. Such properties led the British linguist Geoffrey Sampson to say: "Whether or not it is ultimately the best of all conceivable scripts for Korean, Han'gul must unquestionably rank as one of the great intellectual achievements of humankind."

No orthography is a pure system. The clearest example of logographic writing, Chinese, consists not only of characters representing meanings but also of secondary characters based on sound similarity for representing meanings that were difficult to picture. It therefore relies upon both word-based and sound-based principles. On the other hand, alphabets, which are primarily sound-based, also use fixed letter strings to represent the same meaningful unit even if the pronunciation of that unit varies in different contexts. So, for example, the common spelling for the root *photo* is preserved in the words *photograph* and *photography* even though they are pronounced somewhat differently. Conversely, alphabets often provide different graphic representations for homophones (words that sound identical but have different meanings) the more clearly to distinguish their meanings, as in *meat, meet, mete; pain, pane; be, bee.* The morphemic unit is so fundamental to the reading process that some linguists have concluded that for an orthography to be practical and efficient, it is more important to provide an invariant visual form for each meaningful unit than for each sound unit.

The shaping of a writing system to make it suitable for a wide range of cultural purposes required other developments besides the invention of a system of characters for representing linguistic form. To facilitate fast and accurate recognition, the form of writing was improved by introducing spaces between the words, developing conventions for punctuation and paragraphing, and simplifying graphic forms. This evolution continued through the invention of printing and the invention of type fonts. And to exploit the aesthetic properties of the writing system, artistic forms of writing were developed (see below *Calligraphy*).

HISTORY OF WRITING SYSTEMS

While speaking is a universal human competence that has been characteristic of the species from the beginning and that is acquired by all normal human beings without systematic instruction, writing is a technology of relatively recent history that must be taught to each generation of children. Historical accounts of the evolution of writing systems have until recently concentrated on a single aspect, increased efficiency, with the Greek invention of the alphabet being regarded as the culmination of a long historical evolution. This efficiency is a product of a limited and manageable set of graphs that can express the full range of meanings in a language. As Eric Havelock wrote, "At a stroke the Greeks provided a table of elements of linguistic sound not only manageable because of economy, but for the first time in the history of *homo sapiens,* also accurate." Ignace Gelb distinguished four stages in this evolution, beginning with picture writing, which expressed ideas directly; followed by word-based writing systems;

Consonantal systems (margin note, left column)

Featural systems (margin note, right column)

then by sound-based syllabic writing systems, including unvocalized syllabaries or consonantal systems; and concluding with the Greek invention of the alphabet.

The invention of the alphabet is a major achievement of Western culture. It is also unique; the alphabet was invented only once, though it has been borrowed by many cultures. It is a model of analytic thinking, breaking down perceptible qualities like syllables into more basic constituents. And because it is capable of conveying subtle differences in meaning, it has come to be used for the expression of a great many of the functions served by speech. The alphabet requires little of the reader beyond familiarity with its orthography. It allows the reader to decipher words newly encountered and permits the invention of spellings for new patterns of sound, including proper names (a problem that is formidable for nonalphabetic systems). Finally, its explicitness permits readers to make a relatively sharp distinction between the tasks of deciphering and interpreting. Less explicit orthographies require the reader first to grasp the meaning of a passage as a whole in order to decide which of several possible word meanings a particular graphic string represents.

It must be remembered, however, that efficiency depends not only on the nature of the writing system but also on the functions required of it by its users, for orthographies are invented to serve particular cultural purposes. Furthermore, an orthography invented to satisfy one purpose may acquire new applications. For instance, writing systems invented to serve mnemonic purposes were subsequently elaborated and used for communicative and archival purposes. Orthographies were not invented as art forms but once invented could serve aesthetic functions.

Notions of explicitness of representation depend on the morphophonemic structure of the language. An alphabet was a notable advance for representing the Greek language but not necessarily for representing a Semitic language. Moreover, for languages such as Chinese and Japanese, which have simple syllabic structure and a great number of homophones, a writing system that depended on phonological structure, such as a syllabary or an alphabet, would be extremely inefficient. It is with such factors in mind that more recent accounts of writing systems have stressed how many different orthographies may function efficiently, given the particular language they are used to represent. Just as linguists have abandoned the notion of progressive evolution of languages, with some languages ranking as more primitive than others, so historians of writing have come to treat existing orthographies as appropriate to the languages they represent.

Nonetheless, all contemporary orthographies have a history of development, and there are many common features in these histories. It is unlikely that writing was invented only once and then borrowed by different cultural groups. While all Western writing systems may be traced back to the beginnings of symbol-making in Sumer, there is no reason to believe that Oriental writing systems were borrowed from the Sumerian form. Consequently, there are two quite separate histories of writing, that of the writing system developed by the Sumerians and that of the one developed by the Chinese.

Sumerian writing. The outline of the development of the Sumerian writing system has been worked out by paleographers. It has long been known that the earliest writing system in the world was Sumerian script, which in its later stages was known as cuneiform. The earliest stages of development are still a matter of much speculation based on fragmentary evidence. The French-American archaeologist Denise Schmandt-Besserat, building on a hypothesis advanced by Pierre Amiet of the Louvre, has demonstrated a series of small steps leading from the use of tokens for simple bookkeeping purposes to the development of written tablets on which graphs of the script stand for morphemes of spoken Sumerian. Archaeologists have discovered in lower Mesopotamia (now southern Iraq) large numbers of small, distinctively shaped clay objects. These are thought to date back as far as early as 8000 BC, about the time that hunter-gatherer societies were giving way to an agricultural way of life. A greatly elaborated set of these clay shapes, some shaped like jars and some like various

animals, and occasionally inserted in clay envelopes, date from 3500 BC, about the time of the rise of cities. Some of the envelopes have markings corresponding to the clay shapes inside. Moreover, these markings are more or less similar to the shapes drawn on clay tablets that date back to about 3100 BC and that are unambiguously related to the Sumerian language. These markings are thought to constitute a logographic form of writing consisting of some 1,200 different characters representing numerals, names, and such material objects as cloth and cow.

The theory advanced to explain this transformation by Schmandt-Besserat is that the clay shapes are tokens representing agricultural goods such as grain, sheep, and cattle and that they were used as a form of bookkeeping. The multiplication of types of tokens could correspond to the increase in the number of kinds of goods that were exchanged with the rise of urbanization in the 4th millennium BC. Tokens placed in an envelope might have constituted a sort of "bill of lading" or a record of indebtedness. To serve as a reminder of the contents of the envelope, so that every reader would not need to break open the envelope to read the contents, corresponding shapes were impressed upon the envelope. But if the content was marked on the envelope, there was no need to put the tokens in an envelope at all; the envelope could be flattened into a convenient surface and the shapes impressed on it. Now that there was no need for the tokens at all, their message was simply inscribed into the clay. These shapes, drawn in the wet clay with a reed stylus or pointed stick, constituted the first writing.

The historical record is much more explicit after 3200 BC and reveals clearly the stages involved in the evolution from a limited system of notation suitable for recording particular events into a full, general-purpose orthography. Archaic Sumerian used mostly graphs representing numerals, names for objects, and names of persons. Graphs for numerals were geometric shapes, while those for objects were often stylized pictures of the things they represented. Yet the system was a genuine logographic writing system generally adequate to economic and administrative purposes (see below *Systems of writing: Cuneiform*). With the substitution of a blunt writing stylus for a pointed one, the symbols become less picturelike and more conventionalized. The writing system takes the name cuneiform from the shape of the strokes that form the symbols (from Latin *cuneus,* "wedge").

The next major stage in the evolution of Sumerian writing was the adoption of the phonographic principle, the use of a sign to represent a common sound rather than a common meaning. The graph representing "water" appears to have been used also to represent the locative suffix "in" because the latter sounded the same as, or similar to, the word "water." It is as if in English a person used the word for ball to stand for the person named Bill on the grounds that it is easy to represent the ball with a circular graph while there is no obvious way to represent Bill, and the two words sound similar. The Sumerian script, however, remained primarily logographic and resorted to phonographic signs only when forced to, for representing unpicturable words and for distinguishing ambiguous graphs. Sumerian script was adopted in the 3rd millennium BC by the Akkadians, who greatly expanded the phonographic properties of the script. The Assyrians and the Babylonians, both speaking dialects of the Akkadian language, were responsible for most of the cuneiform writing in a form known today as Akkadian cuneiform.

While cuneiform had many graphs that represented syllables, many syllables were not represented. The methods used for representing syllables that did not have distinctive graphs were quite unsystematic. The first writing system consistently based on the sound structure of a language was Linear B, a Mycenaean Greek orthography developed around 1400 BC and deciphered in modern times by an English architect, Michael Ventris, in 1952. The script is strictly syllabic; each consonant-vowel pair is given a distinctive graph. As an example, a set of syllables that an alphabetic system would represent with the consonant p plus a vowel are all represented in Linear B by different graphs. Although the script is highly systematic, it provides
a limited representation of the phonology of Mycenaean Greek. Greek contains many syllables that are not simple consonant-vowel combinations, and not all consonantal sounds are followed by vowels. Linear B is thus an incomplete script for representing the phonological structures of the spoken language. Hence, there are usually several ways of reading a series of Linear B graphs, and a correct reading depends upon the reader's knowing what the text is about.

The final stage in the evolution of writing systems was the discovery of the alphabetic principle, the procedure of breaking the syllable into its constituent consonantal and vowel sounds. According to Geoffrey Sampson, the British linguist, "Most, and probably all, 'alphabetic' scripts derive from a single ancestor: the Semitic alphabet, created sometime in the 2nd millennium [BC]." The Semitic script was invented by speakers of some Semitic language, possibly Phoenician, who lived in the northern part of the Fertile Crescent. Modern versions of Semitic script include the Hebrew script and the Arabic script. Their most prominent characteristic is that they have graphs for consonants but not for vowels.

The inventors of the Semitic orthography apparently took the acrophonic principle, that of representing sounds by pictures of things whose names begin with that sound, from Egyptian hieroglyphic, a form of writing not different in principle from Akkadian cuneiform. The hieroglyphic sign ∿∿∿ , depicting waves of water, represented the sound /n/, the first sound of the spoken word for water. By means of this principle a 22-graph system was constructed with a memorized order, beginning *alef, bet, gimel,* that was suitable for representing a full range of meanings. These graphs represented the consonants of the language, vowels remaining unrepresented. This fact has led some scholars, notably Gelb and Havelock, to claim that Semitic scripts are not true alphabets but rather unvocalized syllabaries. Other scholars, noting that the graphs represent consonants rather than syllables—for example, *pa, pe, pi, po,* and *pu* would all be represented by the same character—insist that the script is an alphabet. The controversy is circumvented by referring to Semitic scripts, following Sampson, as consonantal writing systems. While such a script would be greatly limited in explicitness or completeness for a language with complex syllable structure such as English, it is relatively complete for Semitic languages in which vowel differences are rarely contrastive.

To illustrate, the following oral forms have in common the three consonantal phonemes /k/, /t/, and /b/ with different vowel sounds interdigitated. The meanings all contain the root meaning "write," and the vowel differences mark subject, tense, and aspect: *katab* "he wrote," *katabi* "I wrote," *katebu* "they wrote," *ketob* "write," *koteb* "writing," *katub* "being written." All are written simply *ktb.*

Because vowel sounds generally distinguish grammatical rather than lexical meaning, some Semitic writing systems never developed any device for representing them. This is not necessarily a flaw in the orthography. Indicating the vowels could cause some confusion for the reader because instead of a single root there would now be a multiplicity of written words, each reflecting a particular grammatical context. Nonetheless, ignoring the vowels does result in an orthography that is far from explicit or complete; many ambiguities in decoding remain. Consequently, some scripts, such as Hebrew, added *matres lectionis,* literally, "mothers of reading," a pointing system to distinguish the vowel sounds. These were used especially for preserving the precise reading of sacred texts. To this day they are used in books written to be read by beginning readers and in poetry and other writings of which the prior knowledge of the reader may not be sufficient to reduce the residual ambiguity.

The transition from consonantal writing to alphabetic writing, writing with full representation of both consonants and vowels, occurred when the Semitic script was adapted to the Greek language. This occurred about 1000–900 BC. Scholars have traditionally considered the Greek invention as a stroke of genius. While not minimizing the significance of the Greek invention, it is now recognized that the invention of the alphabet was, in fact, the rather straightforward consequence of applying a script invented for representing one kind of language to a quite different kind.

The letters used by the Greeks to represent consonantal sounds were borrowed rather directly from the Semitic script. What was distinctive was that the Greeks used six of the Semitic letters, those that represented sounds that did not occur in Greek, to represent vowel sounds. Greek, like English, is an Indo-European language that uses vowel distinctions to make lexical contrasts. Moreover, words may consist simply of vowels, words may begin with vowels, and words with adjacent vowels are not uncommon. Such forms are rare in Semitic languages in which simple consonant-vowel syllable structures predominate and in which vowel differences usually mark only grammatical inflections. Sampson has suggested that in the Semitic language some of the consonants that preceded a vowel sound may have been nonphonemic to the Greeks, who thus in hearing the syllable would have heard only a vowel corresponding to a vowel already prominent in the Greek language. *(margin: Greek alphabet)*

The Romans borrowed the Greek alphabet (along with many Greek words and much of Greek culture) to form the Roman, or Latin, alphabet. Written "learned" Latin was the language of state and of scholarship in Europe until the end of the Middle Ages. Further developments of the alphabet resulted from changes in the phonology of Latin and of the Romance languages that evolved from it. For English, the differentiation of all the 26 letters was completed only in the 19th century.

While the invention of logographic writing, the later invention of the principle of phonetization, the analysis of syllables into a consonantal writing system, and the addition of vowels to make a full alphabet do constitute progress toward an efficient, economical, explicit, and complete writing system, this progress was not simply a matter of increasing insight. Advances resulted from attempts to apply a writing system invented for one language to another language for which it was not completely appropriate. Yet the accumulated discoveries yielded an analysis of deeper and deeper levels of linguistic structure of the type associated with discoveries in the natural sciences. For this reason, writing has almost always been the means not only for transcribing speech but also for uncovering its underlying structure. That is, to a large extent writing is what has made people conscious of the properties of speech.

Observation of children learning to read and write an alphabetic orthography suggests that children pass through some of the same stages in interpreting the code that the writing system itself passed through in the course of its development. The youngest child's hypothesis about writing is that words must be similar in some way to the objects they represent. Thus, at the earliest stage children think that the word "train" must be represented by a long word because it is a long thing. Similarly, they think that "two little pigs" must be represented by two words, one for each pig, and so on. Later, they invent the hypotheses that writing represents words rather than things and that these words are series of sounds. At this point children may write the word with a series of consonants; cat becomes *kt.* Only later do they recognize the alphabetic principle that words must be written with both consonants and vowels.

Yet the evolution of the alphabet, an invention of enormous importance for Greek and for all Indo-European languages, was of little use for Semitic languages, in which the vowels played a smaller role than in Greek. And it was of no use at all for Chinese, which is a monosyllabic language with a great many homophones.

Chinese writing. Chinese is a language with clearly distinguished syllables, each of which corresponds to a meaningful unit, a morpheme. As it is an "isolating" language, rather than an inflected language like Latin or, to a lesser degree, English, each morpheme is represented separately by a separate syllable. Whereas in English one word, for example, *make,* yields, when inflected, a family of related words (*make, makes, making, made,* etc.), in Chinese one character would represent one morpheme (*e.g., make*). Because each morpheme is represented by a different

character, and because the number of morphemes in a language is far larger than the number of syllables, such a writing system needs an extremely large number of characters or graphs.

It is not known when Chinese writing originated. The earliest known samples are from the time of the Shang dynasty (18th–12th century BC), but by then it was already a highly developed system, essentially similar to its present form. By 1400 BC the script included some 2,500 to 3,000 characters, most of which can be read to this day. The script was fixed in its present form during the Ch'in period (221–206 BC). The earliest graphs were schematic pictures of what they represented; the graph for "man" resembled a standing man, that for "woman" depicted a kneeling figure, perhaps doing housework.

Because basic characters or graphs were "motivated," that is, the graph was made to resemble the object it represented, it has sometimes been concluded that Chinese writing is ideographic, representing ideas rather than the structures of a language. It is now recognized that the system represents the Chinese language by means of a logographic script. Each graph or character corresponds to one meaningful unit of the language, not directly to a unit of thought.

Although it was possible to make up simple signs representing common objects, many words were not readily picturable. To represent such words, the phonographic principle was adopted. A graph that pictured some object was borrowed to write a different word that happened to sound similar. With this invention the Chinese approached the form of writing invented by the Sumerians. However, because of the enormous number of Chinese words that sound the same, to have carried through the phonographic principle would have resulted in a writing system in which many of the words could be read in more than one way. That is, a written character would be enormously ambiguous.

The solution to the problem of ambiguity of characters, a solution adopted about 213 BC, was to distinguish two words having the same sound and represented by the same graph by adding another graph to give a clue to the meaning of the particular word intended. Such complex graphs or characters consist of two parts, one part suggesting the sound, the other part the meaning. The system was then standardized so as to approach the ideal of one distinctive graph representing each morpheme in the language. The limitation is that a language that has thousands of morphemes would require thousands of characters. As the characters are formed from simple lines in various orientations and arrangements, they came to possess great complexity.

Not only did the principle of the script change with time, so too did the form of the graphs. The earliest writing consisted of carved inscriptions. Before the beginning of the Christian Era, the script came to be written with brush and ink on paper. The result was that the shapes of the graphs lost their pictorial, "motivated" quality. The brushwork allowed a great deal of scope for aesthetic considerations.

The relation between the written Chinese language and its oral form is very different from the analogous relation between written and spoken English. In Chinese many different words are expressed by the identical sound pattern—188 different words are expressed by the syllable /yi/—while each of those words is expressed by a distinctive visual pattern. A piece of written text read orally to another person is often quite incomprehensible because of the large number of homophones. In conversation literate Chinese speakers frequently draw characters in the air to distinguish between homophones. Written text, on the other hand, is completely unambiguous. In English, by contrast, writing is often thought of as a reflection, albeit imperfect, of speech.

To make the script easier to read, a system of transcribing Chinese into the Roman alphabet was adopted in 1958. The system was not intended to replace the logographic script but to indicate the sounds of graphs in dictionaries and to supplement graphs on such things as road signs and posters. A second reform simplified the characters by reducing the number of strokes used in writing them. Sim-

plification, however, tends to make the characters more similar in appearance; thus they are more easily confused, and the value of the reform is limited.

Most scholars now believe that neither the logographic Chinese writing system nor the alphabetic writing system of Indo-European possesses any overall advantage. The Chinese system requires more memorization, while the alphabet requires more analysis and synthesis; both appear to be relatively optimal devices for the transcription of their respective, very different, languages.

A second factor makes the use of a logographic system particularly significant for Chinese. A single logographic system is capable of representing very different spoken forms. As was mentioned earlier, the numerals *1, 2,* and *3* are logograms that represent different words in a number of different languages.

Chinese logographs form a common medium of communication for a vast nation because they can be read by people speaking mutually incomprehensible dialects of Chinese. Since the Communist Revolution the grammar and vocabulary of modern Mandarin Chinese has served as the standard written language.

Japanese writing.   The Japanese came into contact with Chinese culture during the Chinese Han dynasty (206 BC–AD 220), and they began to write their own language in the 5th century AD, basing their writing system on the Chinese model. But the two languages are fundamentally different in structure; whereas Chinese words are monosyllables, Japanese words often consist of several syllables, and whereas Chinese is an isolating language, Japanese is an inflected language. To write such a language, the Japanese developed a mixed system, partly logographic, based on the Chinese system, and partly syllabic, using the same characters in a second way for their sound values. In *kun* writing Chinese characters were used to represent Japanese words that have a similar meaning, while other characters were adopted to represent sounds.

In the 8th century the phonographic principle was applied more systematically in a writing system called *man'yōgana,* a syllabary very similar in form to the Semitic alphabet. However, given the large number of homophones and the fact that *man'yogana* was combined with *kun* writing, it was almost impossible to establish a single correct reading of a text. Indeed, scribes took pride in being able to read the same text in various ways.

In the 9th or 10th century two sets of syllabic signs evolved, one called *hiragana,* or "plain" *kana,* which consists of simplified outlines, written cursively, of Chinese characters, the other called *katakana,* or "partial" *kana,* which consists of carefully written parts of the original Chinese characters. Writing with the full Chinese characters is called *kanji.* The two sets of *kana* characters are limited as are other syllabaries in that they are not unambiguous; *kanji* are unambiguous but are very complex visually. Consequently, modern Japanese writing uses a combination of characters from all three of these systems. In 1946 a standardizing reform established a limited list of 1,850 *kanji* (enlarged to 1,945 in 1981) and encouraged the use of *kana* for all other words. Modern written Japanese uses many more *hiragana* graphs than *kanji* in a piece of text.

Even with modern reforms, written Japanese is difficult to read unambiguously because of the great degree of homophony in the vocabulary. The word *kan,* for example, means "sweet," "be affected," "print," "be accustomed to," "view," "investigate," "slow," "tube," "enjoy," "a volume," "Chinese," and "Korean," among others. As a result a reader must know rather precisely what is being discussed in order to read a text accurately. Poetry, in particular, takes quite a different form in Japanese than in Indo-European languages.

Korean writing.   Korea, too, adopted its institutions and culture from the Chinese. Until the 20th century the normal medium of written communication was in Chinese, using the Chinese writing system. But beginning in about the 6th century the Chinese script was adapted to write Korean. The application of Chinese script to the Korean language created problems almost identical to those that arose in using Chinese to write the Japanese language. Yet

the borrowed *kanji* script continues to be used for some purposes to this day. The most remarkable development in Korean writing was the invention of Han'gŭl by King Sejong in 1446. It is a featural script consisting of some 28 letters that have a systematic visual structure directly related to the phonetic features of the phonemes. This writing system owes nothing to the Chinese orthography (see above *Types of writing systems*).

Because the principles employed by various writing systems vary greatly and because the languages they represent are organized so differently, it is difficult to state any general principles of the evolution of writing systems. Yet it appears that they all began with motivated pictorial signs representing objects. To turn such signs into a general orthography required the recognition that the signs must represent sound patterns and the consequent invention of the phonographic principle. Depending on the language, such sound-based systems developed in two directions. Western scripts went furthest in the phonographic direction, representing words by means of syllables and syllables by means of consonantal writing systems and eventually developing a full vocalic alphabet. Eastern scripts preserved the logographic principle even though some of the logographs were sound-based; each word was represented by a distinctive visual character. Only one practical orthography, Korean, adopted a featural system, and that invention bore little or no relation to neighbouring orthographies.

LITERACY: THE USES OF WRITING

The rise of literacy. The invention of devices for representing language is inextricably related to issues of literacy; that is, to issues of who can use the script and what it can be used for. Competence with written language, both in reading and writing, is known as literacy. High levels of literacy are required for using scripts for a wide range of somewhat specialized functions. When a large number of individuals in a society are competent in using written language to serve these functions, the whole society may be referred to as a literate society.

Just as scripts have a history, so, too, does literacy have a history. This history closely reflects the increasing number of ways in which written materials have been used and the increasing number of readers who have been able to use them. Scripts were elaborated to serve new purposes; more importantly, new kinds of writing systems permitted them to serve a wider range of purposes by a larger number of individuals.

Although the uses of writing reflect a host of religious, political, and social factors and hence are not determined simply by orthography, two dimensions of the script are important in understanding the growth of literacy: learnability and expressive power. Learnability refers to the ease with which the script can be acquired, and expressive power refers to the resources of the script for unambiguously expressing the full range of meanings available in the oral language. These two dimensions are inversely related to each other. Simple, restricted scripts are readily learned. Pictographic signs such as those used in "environmental writing" and logographic scripts with a limited set of characters are easiest to learn and, indeed, are acquired more or less automatically by children. Syllabaries such as the Cree syllabary are reported to be learnable in a day, while the indigenous Liberian Vai syllabary is learned in a few days. Consonantal scripts and alphabets are difficult to learn and usually require a few years of schooling. Full logographic systems, such as Chinese, or mixed systems, such as Japanese, are difficult to acquire because they require the memorization of thousands of distinctive characters. Once learned, however, they appear to function as well as alphabets.

But pictographic signs and logographic scripts with a limited, readily learnable set of graphs are restricted to expressing a limited range of meanings. Syllabaries are highly ambiguous and hence dependent on knowledge not only of the script but also on the likely content of the message. Syllabaries therefore serve a restricted set of functions, primarily personal correspondence. They are of limited use in expressing novel meanings that could be read in the same way by all readers of the script. Consonantal and

alphabetic writing systems can express essentially all the lexical and grammatical meanings in the language (but not the intonation) and are thus highly suitable for the expression of original meanings. They constitute an ideal medium for technical, legal, literary, and scientific texts that must be read in the same way by readers dispersed in both time and space. Some scholars have held that the high degree of literacy in the West is a consequence of the optimality of the alphabet in balancing the two dimensions of learnability and expressive power. Such generalizations, however, ignore the fact that the "optimal" balance may differ from language to language. A consonantal writing system is almost as complete for Hebrew as the alphabet is for Greek, but a consonantal writing system would be hopelessly ambiguous for Greek. Similarly, a syllabary or an alphabet would be quite useless for Chinese, a language with a staggering degree of homophony. Logographic systems achieve a comparable level of explicitness by the addition of new characters, but the ease of addition is traded off against the ease of acquisition. Instead of attempting to determine whether one system is better than another, it is perhaps more reasonable to assume that each script is optimal for the language it represents and for the functions it has evolved to serve.

The ease of acquisition of a script is an important factor in determining whether a script remains the possession of an elite or whether it can be democratized, that is, turned into a possession of ordinary people. Syllabaries are readily learned, but their residual ambiguity tends to restrict their uses. Alphabets have been viewed by many historians as decisive in the democratization of writing; alphabetic writing could become a possession of ordinary people and yet serve a full range of functions. However, democratization of a script appears to have more to do with the availability of reading materials and of instruction in reading and the perceived relevance of literacy skills to the readers. Even in a literate society, most readers learn to read only a narrow range of written materials; specialized materials, such as those pertaining to science or government, remain as the domain of elites who have acquired additional education.

The second factor determining the social breadth of the use of writing is the range of functions that a script serves. The functions served are directly related to the orthography. Early forms of writing served an extremely narrow range of functions and were wholly unsuitable for others. While tokens served for simple record keeping, and early Sumerian writing was useful for a range of administrative purposes, a relatively complete script is required for writing histories, edicts, treaties, and scientific and literary works that, to be useful, must be read in the same way by all readers. Considerable scholarly controversy surrounds the question of the role of the invention of more complete or explicit scripts, such as the alphabet, in the evolution of these more specialized uses of language. If the alphabet were decisive, one could look for the basis of many of the particular features of Western culture in the invention of an alphabetic orthography.

This question is far from resolved. Historically, the rise of cities coincided with the development of a script suitable for serving bureaucratic purposes. Later, the scientific and philosophical tradition that originated in classical Greece and that prevails in the West to this day developed along with the alphabet. Many writers, including Eric Havelock, have maintained that the alphabet was a decisive factor in the cultural development of the West. Marshall McLuhan and Walter Ong have claimed that the rise of literacy and the decline of "orality" in the later Middle Ages were fundamental to the cultural flowering known as the Renaissance.

It is perhaps characteristic of alphabet-based conceptions of literacy to draw a strict distinction between reading and interpreting. As interpretation came to be seen as interpolation into or distortion of the text, the attempt was made to write texts in such a manner as to reduce the possibility of variant interpretations. This resulted in the attempt to write texts with univocal meanings, texts that mean neither more nor less than what they say. To achieve this required the formalization of grammatical structures, the conventionalization of meanings of terms, and the inven-

tion of standard punctuation. Such textual developments were especially important for the specialized functions of science and philosophy. The distinction between meaning and interpretation fostered the idea that texts have a literal meaning, that knowledge can be completely expressed by means of such literal meanings, and that texts can be autonomous and objective. In the Western tradition, knowledge is treated as if it were an ideal text, as something that is regarded by most learners as given rather than created. These assumptions about meaning were important to both the literary and the scientific traditions that took form in western Europe in the 17th century and that continue to this day.

The particular form of writing, whether logographic, syllabic, or alphabetic, is less important than the existence of some form that is general enough to serve a full range of purposes. Literate societies, whether Chinese or Sumerian, have always been esteemed by nonliterate societies, which have borrowed heavily from them. Thus the Romans borrowed Greek literacy, and the Japanese and Koreans borrowed Chinese literacy. Once adopted and used for administrative, scientific, legal, and literary purposes, literacy altered the society that it was part of in a variety of ways.

Writing allows exactly repeatable statements to be circulated widely and preserved. It allows readers to scan a text back and forth and to study, compare, and interpret at their leisure. It allows writers to deliberate over word choice and to construct lists, tables, recipes, and indexes. It fosters an objectified sense of time, a linear conception of space. It separates the message from the author and from the context in which it was written, thereby "decontextualizing," or universalizing the meaning of, language. It allows the creation of new forms of verbal structure, like the syllogism, and of numerical structures, like the multiplication table. When writing becomes a predominant institutional and archival form it has contributed to the replacement of myth by history and the replacement of magic by skepticism and science. Writing has permitted the development of extensive bureaucracy, accounting, and legal systems organized on the basis of explicit rules and procedures. Writing has replaced face-to-face governance with written law and depersonalized administrative procedures. And, on the other hand, it has turned writers from scribes into authors and thereby contributed to the recognition of the importance of the thoughts of individuals and consequently to the development of individualism.

Literacy and schooling.   Whereas oral language is learned quite independently of whether it is taught or not, literacy is largely dependent upon teaching. While some local or indigenous scripts are taught relatively informally by parents or someone who knows the script well, widespread or universal literacy is dependent upon schooling. Indeed, in many societies schooling and literacy have been almost synonymous. Schools in such diverse places as Sumer and China developed concurrently with the development of a full writing system and were concerned primarily with teaching first adults and later children to read and write. And it is inconceivable that modern, technological societies could survive without schools to develop high levels of literacy.

Although schooling is critical to the development of literacy, it is not, by itself, sufficient. Historians have shown that the level of literacy produced by the schools of any society is directly tied to the functions and levels of literacy in the society as a whole. Consequently, it is unrealistic to expect that a modern, literate society could be created simply through establishing schools and teaching children to read. Schools tend to reflect the society rather than to change it dramatically. Schooling in Western societies is successful in achieving relatively high levels of literacy in part because of the literacy practices in the larger society. When compulsory schooling was introduced in Britain, Europe, and America in the 19th century, it was nurtured by an environment of "lay" literacy in which as much as 75 percent of the population could use written materials for such informal purposes as keeping diaries, reading and writing notes and letters, and personal record keeping. Such a climate of widespread practical literacy is important to the effectiveness of schooling. The relation between literate practices in the home and the level of literacy achieved by children in the school has been amply documented.

It is common to think of literacy as the simple ability to read and write. In part such thinking is a consequence of the naive assumption that alphabetic literacy is a matter simply of decoding graphs into sounds and vice versa. In fact, literacy involves competence in reading, writing, and interpreting texts of various sorts. It involves both skill in decoding and higher levels of comprehension and interpretation. These higher levels depend upon knowledge both of specialized uses of language and of specialized bodies of knowledge. The intimate relations among language, literacy, and specialized bodies of knowledge have contributed to the identification of literacy with schooling.

As different scripts serve different functions and make different demands upon readers, it is a complex matter to define literacy in universal terms and so to judge the literacy levels of a society at different periods or to compare one society with another. Scripts that, because of incompleteness or inexplicitness, rely heavily upon the prior knowledge of reader and writer remain the domain of a specialized elite, as did cuneiform, or they are used for rather restricted purposes, as is Cree syllabic. Scripts that are relatively explicit and complete permit a reader who is unfamiliar with a text to read it in a reliable way and hence can be used for a much broader range of functions.

The form of the script may be less crucial than the range of functions a script serves and the breadth of its readership, that is, the degree of literacy of the society. With the growth of readership come increased production of materials to be read, increased number of social functions the script is used for, and the invention of new, more specialized genres of writing. The novel form, for example, was invented in Europe only in the 17th century, when there was a broadly based reading public. Other specialized uses of writing developed much earlier. As European societies became more literate during the Middle Ages, writing came to be used for functions that earlier had been performed by oral language and by ritual. Indenture of servants, deeding of property, evidence at trials, and accounts of the lives of saints all came to be functions of written texts. As literacy began to be required for these vital social purposes, oral language came to be seen as loose and unruly and lacking in social authority. And people who could not read and write came to be regarded as rude and ignorant—in short, unlettered.

Rising levels of literacy in Europe were closely related to great social transformations, notably the Protestant Reformation and the rise of modern science. The right to read the Bible for oneself and to discover its meaning was the fundamental tenet of Protestantism, and the private study and verification of written texts was important to science. Both of these functions were enormously facilitated by the development of printing from movable type and by the translation of important books from scholarly Latin into vernacular languages. With the increase in the uses of writing and the spread of printing there were more texts to read. Concurrently, European society as a whole became more literate in two ways: more individuals learned to read and write their native tongues, and even those who could not themselves read and write came to rely upon written documents as loci of authority and significance. In the 18th and 19th centuries in western Europe and in America, even before the establishment of compulsory schooling, more than half of the population had some competence in reading and writing. Compulsory schooling had, by the end of the 19th century, made some level of literacy more or less universal.

Partly because of the close tie between schooling and literacy, literacy levels are often defined exclusively in terms of the number of years that a person has attended school. Educational institutions usually differentiate a basic, or functional, level of literacy, roughly equivalent to six years of schooling, from a high level of literacy, a level of competence roughly equivalent to 10 to 12 years of schooling. Such categorical distinctions have been criticized because they are insensitive to the diversity of particular uses of literacy in even a literate society and the irrelevance of

Rise of literacy in Europe

the school to many of them. Many people incapable of or uninterested in reading continuous texts pertaining to science and literature nonetheless read menus, catalogs, letters, labels, warnings, invoices, and a range of other materials of relevance and interest to them.

Moreover, literacy levels are judged against a sliding standard. The more literate the society becomes, the higher a standard of literacy is judged as functional. In Sweden in the 17th century a person was judged as literate, and allowed to marry, if he could read bits of the catechism and sign the church registry. In the United States at the time of World War II, when soldiers were screened for military service the army defined a minimal level of literacy as that normally achieved in the fifth grade (about 10 years of age). By 1966 the criterion of functional literacy in the United States had been raised to completion of secondary school by the Adult Education Act passed by Congress in that year.

Using this criterion, some writers have claimed that 25 percent of U.S. adults are functionally illiterate. Some commentators see in such figures a social problem of great importance and promote various programs of educational reform intended to produce higher levels of literacy. However, most scholars criticize such statistics as meaningless on two grounds. First, they are based on a questionable identification of competence with success in a single institution, the school, rather than in the relevant contexts of application. Second, they do not adequately reflect the extent to which even those individuals who are classified as functionally illiterate depend upon and participate in literate activities in modern societies. Such persons know how to participate in a great many literacy-based institutions—how to read signs, labels, and letters, how to deal with ballots, how to sign checks and write notes—if not the special literate skills usually acquired in school. More important, even if they are not highly skilled in literate activities they know what it is to be literate, what texts are, how they are written and interpreted, how they accumulate to form a tradition, and how they are consulted and used in multiple ways in a literate society.

As an alternative to simply identifying levels of literacy with years of schooling, some scholars have distinguished levels of literacy in another way. Environmental or lay literacy is the term used to designate that form of unspecialized competence involved in generally dealing with a literate environment. Such literacy need never be taught. It is a type of literacy that is acquired through participating in a literate environment in which written signs, labels, trademarks, headlines, sports scores, and the like are ubiquitous. Such a general, if low, level of literacy, which stands somewhat apart from the particular skills of reading and writing, first arose in Europe in the later Middle Ages with the development of what the Canadian historian Brian Stock refers to as "textual communities." A textual community consisted of a band of believers formed around an interpreter who read and interpreted religious texts. Because the authority of the teacher rested in the text rather than in the church, members of the community came to know certain general truths about texts and about writing: that they could be read, understood, studied, consulted; that they were more reliable than hearsay; that they were permanent; and that they possessed authority. Everyone in a literate society is literate in this sense; all know the nature, uses, and functions of writing even if they do not personally practice it.

A literate society is also dependent upon the development of elite literacy, a high level of literate competence, possessed by a relatively small percentage of the population, in such specialized fields of endeavour as science, law, or literature. High levels of literate competence involve learning a somewhat specialized vocabulary as well as the nuances of meaning that are relevant to lexical choice. It is estimated that literate people have a reading vocabulary, consisting of words that are encountered only in reading and writing, that may be more than double the size of their ordinary speaking vocabulary. In addition to specialized vocabularies, high levels of literate competence involve knowledge of specialized grammatical constructions that serve to set out explicitly the logical form of an argument

Lay literacy

Elite literacy

and of specialized genres or literary forms such as description, explanation, argument, and instructions that can be used for building complex linguistic structures or genres, such as narrative and expository texts. These specialized skills require for mastery many years of formal schooling. Once such forms are acquired, in literate contexts they can also be used in speech. For this reason literacy is not tied exclusively to writing; just as one can write in an essentially oral style, so one can speak in a manner characteristic of written language. Literacy makes it possible to speak a written language. (D.R.O.)

Systems of writing

CUNEIFORM

Cuneiform (a coinage from Latin and Middle French roots meaning "wedge-shaped") has been the modern designation, from the early 18th century onward, for the most widespread and historically significant writing system in the ancient Middle East. Its active history comprises the last three millennia BC; its long development and geographic expansion involved numerous successive cultures and languages; and its overall significance as an international graphic medium of civilization is second only to that of the Phoenician-Greek-Latin alphabet.

Origin and character of cuneiform. The origins of cuneiform may be traced back approximately to the end of the 4th millennium BC. At that time the Sumerians, a people of unknown ethnic and linguistic affinities, inhabited southern Mesopotamia and the region west of the mouth of the Euphrates known as Chaldea. While it does not follow that they were the earliest inhabitants of the region or the true originators of their system of writing, it is to them that the first attested traces of cuneiform writing are conclusively assigned. The earliest written records in the Sumerian language are pictographic tablets from Uruk (Erech), evidently lists or ledgers of commodities identified by drawings of the objects and accompanied by numerals and personal names. Such word writing was able to express only the basic ideas of concrete objects. Numerical notions were easily rendered by the repetitional use of strokes or circles. However, the representation of proper names, for example, necessitated an early recourse to the rebus principle—*i.e.,* the use of pictographic shapes to evoke in the reader's mind an underlying sound form rather than the basic notion of the drawn object. This brought about a transition from pure word writing to a partial phonetic script. Thus, for example, the picture of a hand came to stand not only for Sumerian *šu* ("hand") but also for the phonetic syllable *šu* in any required context. Sumerian words were largely monosyllabic, so the signs generally denoted syllables, and the resulting mixture is termed a word-syllabic script. The inventory of phonetic symbols henceforth enabled the Sumerians to denote grammatical elements by phonetic complements added to the word signs (logograms or ideograms). Because Sumerian had many identical sounding (homophonous) words, several logograms frequently yielded identical phonetic values and are distinguished in modern transliteration—(as, for example, *ba, bá, bà, ba₄*). Because a logogram often represented several related notions with different names (*e.g.,* "sun," "day," "bright"), it was capable of assuming more than one phonetic value (this feature is called polyphony).

In the course of the 3rd millennium the writing became successively more cursive, and the pictographs developed into conventionalized linear drawings. Due to the prevalent use of clay tablets as writing material (stone, metal, or wood also were employed occasionally), the linear strokes acquired a wedge-shaped appearance by being pressed into the soft clay with the slanted edge of a stylus. Curving lines disappeared from writing, and the normal order of signs was fixed as running from left to right, without any word-divider. This change from earlier columns running downward entailed turning the signs on one side (see above *History of writing systems*).

Spread and development of cuneiform. Before these developments had been completed, the Sumerian writing system was adopted by the Akkadians, Semitic invaders who established themselves in Mesopotamia about the

Use of the rebus

middle of the 3rd millennium. In adapting the script to their wholly different language, the Akkadians retained the Sumerian logograms and combinations of logograms for more complex notions but pronounced them as the corresponding Akkadian words. They also kept the phonetic values but extended them far beyond the original Sumerian inventory of simple types (open or closed syllables like *ba* or *ab*). Many more complex syllabic values of Sumerian logograms (of the type *kan, mul, bat*) were transferred to the phonetic level, and polyphony became an increasingly serious complication in Akkadian cuneiform (*e.g.*, the original pictograph for "sun" may be read phonetically as *ud, tam, tú, par, lah̬, h̬iš*). The Akkadian readings of the logograms added new complicated values. Thus the sign for "land" or "mountain range" (originally a picture of three mountain tops) has the phonetic value *kur* on the basis of Sumerian but also *mat* and *šad* from Akkadian *mātu* ("land") and *šadû* ("mountain"). No effort was made until very late to alleviate the resulting confusion, and equivalent "graphies" like *ta-am* and *tam* continued to exist side by side throughout the long history of Akkadian cuneiform.

The earliest type of Semitic cuneiform in Mesopotamia is called the Old Akkadian, seen for example in the inscriptions of the ruler Sargon of Akkad (died *c.* 2279 BC). Sumer, the southernmost part of the country, continued to be a loose agglomeration of independent city-states until it was united by Gudea of Lagash (died *c.* 2124 BC) in a last brief manifestation of specifically Sumerian culture. The political hegemony then passed decisively to the Akkadians, and King Hammurabi of Babylon (died 1750 BC) unified all of southern Mesopotamia. Babylonia thus became the great and influential centre of Mesopotamian culture.

Figure 1: Development of cuneiform script from pictographs to Assyrian characters.

The Code of Hammurabi is written in Old Babylonian cuneiform, which developed throughout the shifting and less brilliant later eras of Babylonian history into Middle and New Babylonian types. Farther north in Mesopotamia the beginnings of Assur were humbler. Specifically Old Assyrian cuneiform is attested mostly in the records of Assyrian trading colonists in central Asia Minor (*c.* 1950 BC; the so-called Cappadocian tablets) and Middle Assyrian in an extensive Law Code and other documents. The Neo-Assyrian period was the great era of Assyrian power, and the writing culminated in the extensive records from the library of Ashurbanipal at Nineveh (*c.* 650 BC). — Assyrian cuneiform

The expansion of cuneiform writing outside Mesopotamia began in the 3rd millennium, when the country of Elam in southwestern Iran was in contact with Mesopotamian culture and adopted the system of writing. The Elamite sideline of cuneiform continued far into the 1st millennium BC, when it presumably provided the Indo-European Persians with the external model for creating a new simplified quasi-alphabetic cuneiform writing for the Old Persian language. The Hurrians in northern Mesopotamia and around the upper stretches of the Euphrates adopted Old Akkadian cuneiform around 2000 BC and passed it on to the Indo-European Hittites, who had invaded central Asia Minor at about that time.

In the 2nd millennium the Akkadian of Babylonia, frequently in somewhat distorted and barbarous varieties, became a lingua franca of international intercourse in the entire Middle East, and cuneiform writing thus became a universal medium of written communication. The political correspondence of the era was conducted almost exclusively in that language and writing. Cuneiform was sometimes adapted, as in the consonantal script of the Canaanite city of Ugarit on the Syrian coast (*c.* 1400 BC), or simply taken over, as in the inscriptions of the kingdom of Urartu or Haldi in the Armenian mountains from the 9th to 6th centuries BC; the language is remotely related to Hurrian, and the script is a borrowed variety of Neo-Assyrian cuneiform. Even after the fall of the Assyrian and Babylonian kingdoms in the 7th and 6th centuries BC, when Aramaic had become the general popular language, rather decadent varieties of Late Babylonian and Assyrian survived as written languages in cuneiform almost down to the time of Christ.

Decipherment of cuneiform. Many of the cultures employing cuneiform (Hurrian, Hittite, Urartian) disappeared one by one, and their written records fell into oblivion. The same fate overtook cuneiform generally with astonishing swiftness and completeness. One of the reasons was the victorious progress of the Phoenician script in the western sections of the Middle East and the classical lands in Mediterranean Europe. To this writing system of superior efficiency and economy, cuneiform could not offer serious competition. Its international prestige of the 2nd millennium had been exhausted by 500 BC, and Mesopotamia had become a Persian dependency. Late Babylonian and Assyrian were little but moribund artificial literary idioms. So complete was the disappearance of cuneiform that the classical Greeks were practically unaware of its existence, except for the widely traveled Herodotus, who in passing mentions *Assyria Grammata* ("Assyrian characters").

Old Persian and Elamite. The rediscovery of the materials and the reconquest of the recondite scripts and languages have been the achievements of modern times. Paradoxically the process began with the last secondary offshoot of cuneiform proper, the inscriptions of the Achaemenid kings (6th to 4th centuries BC) of Persia. This is understandable, because almost only among the Persians was cuneiform used primarily for monumental writing, and the remains (such as rock carvings) were in many cases readily accessible. Scattered examples of Old Persian inscriptions were reported back to Europe by western travelers in Persia since the 17th century, and the name cuneiform was first applied to the script by Engelbert Kämpfer (*c.* 1700). During the 18th century many new inscriptions were reported; especially important were those copied by Carsten Niebuhr at the old capital Persepolis. It was recognized that the typical royal inscriptions contained three different scripts, a simple type with about — Persian inscriptions

40 different signs and two others with considerably greater variations. The first was likely to reflect an alphabet, while the others seemed to be syllabaries or word writings. Assuming identical contents in three different languages, scholars argued on historical grounds that those trilingual inscriptions belonged to the Achaemenid kings and that the first writing represented the Old Persian language, which would be closely related to Avestan and Sanskrit. The recognition of a diagonal wedge as word-divider simplified the segmentation of the written sequences. The German scholar Georg Friedrich Grotefend in 1802 reasoned that the introductory lines of the text were likely to contain the name, titles, and genealogy of the ruler, the pattern for which was known from later Middle Iranian inscriptions in an adapted Aramaic (*i.e.*, ultimately Phoenician) alphabet. From such beginnings, he was eventually able to read several long proper names and to determine a number of sound values. The initial results of Grotefend were expanded and refined by other scholars.

Next the second script of the trilinguals was attacked. It contained more than 100 different signs and was thus likely to be a syllabary. Mainly by applying the sound values of the Old Persian proper names to appropriate correspondences, a number of signs were gradually determined and some insight gained into the language itself, which is New Elamite; the study of it has been rather stagnant, and considerable obscurity persists. The same holds true for the Old Elamite of the late 2nd millennium.

Akkadian and Sumerian. The third script of the Achaemenian trilinguals had in the meantime been identified with that of the texts found in very large numbers in Mesopotamia, which obviously contained the central language of cuneiform culture, namely Akkadian. Here also the proper names provided the first concrete clues for a decipherment, but the extreme variety of signs and the peculiar complications of the system raised difficulties which for a time seemed insurmountable. The serious external divergencies between older and newer types of Akkadian cuneiform, the distribution of ideographic and syllabic uses of the signs, the simple (*ba, ab*) and complex (*bat*) values of the syllables, and especially the bewildering polyphony of many notations were only gradually surmised by scholars. Once the Semitic character of the language had been established, the philological science of Assyriology developed rapidly from the closing decades of the 19th century onward, especially because of scholars like Friedrich Delitzsch and, later, Benno Landsberger and Wolfram von Soden.

The Akkadian key

Once Akkadian had been deciphered, the very core of the system was intelligible, and the prototype was provided for the interpretation of other languages in cuneiform. Until the 20th century Sumerian was not definitely recognized as a separate language at all but rather as a special way of noting Akkadian. Even when its independent character was established, the difficulties of interpretation were appalling because of its strange and unrelated structure. After Sumerian finally died out as a living language toward the middle of the 2nd millennium, it lingered on as a cult idiom of Babylonian religion. To facilitate its artificial acquisition by the priesthood, grammatical lists and vocabularies were compiled and numerous religious texts were provided with literal translations into Babylonian. These have facilitated the penetration of unilingual Sumerian texts, and Sumerian studies advanced greatly through the efforts of such scholars as Delitzsch, François Thureau-Dangin, Arno Poebel, Anton Deimel, and Adam Falkenstein.

Hittite and other languages. An important new dimension was added to cuneiform studies in the early years of the 20th century, through the discovery in 1906 of the royal archives of the Hittites at the ancient capital site of Hattusas, near the Turkish village of Boğazköy, east of Ankara. Some years earlier the existence of an Indo-European idiom in some cuneiform letters found in the Egyptian diplomatic archives of the 18th dynasty at Tell el-Amarna had been suspected by Johan Knudtzon. This unlikely surmise was confirmed by Friedrich Hrozný during World War I, when his initial interpretation of the Boğazköy materials proved that the predominant language

in the thousands of tablets was that of the Indo-European Hittites, whose rule in central Asia Minor filled most of the 2nd millennium. The tablets offered no serious cryptological problems, being edited in a type of borrowed Akkadian cuneiform. The interpretation of the unknown language was aided by the partial ideographic nature of the script, which revealed elements of meaning independent of linguistic factors. Even more important was a series of bilingual parallel texts, in which the Akkadian versions served as a clue to the analysis of linguistic structure.

In the absence of close affinity to known languages, which vouches adequate safeguards against the notoriously misleading comparative method of interpretation, inner analysis of the unknown language is the only trustworthy procedure. Hurrian and Urartian are definitely related languages, but neither may yet be safely used to explain the other. Urartian has been solved to some extent with the help of its rather free use of ideograms and the Assyrian versions of two bilingual inscriptions.

Excavations at Ras Shamra in 1929 unearthed the remains of Ugarit. Inscriptions in an unknown simple system of cuneiform were found; the low number of 30 different signs pointed to an alphabetic type. The use of a vertical stroke as word-divider facilitated the decipherment, which was based on the correct assumption that an early North Semitic Canaanite dialect was involved. Thus the script was solved with astonishing speed by Hans Bauer, Edouard Dhorme, and Charles Virolleaud, yielding a Semitic dialect named Ugaritic, closely related to Old Phoenician. Hurrian inscriptions in the same script were also found, as were texts in conventional Middle Babylonian cuneiform.

Influence of cuneiform. The main type of cuneiform, with its inventory of ideograms (including "determinatives" or "classifiers") and phonetic signs, is a word-syllabic system like the Egyptian, hieroglyphic Hittite, Minoan-Mycenaean, proto-Elamite, and proto-Indic. The Sumerian system seems to be the oldest. To what extent it stimulated the origin or influenced the development of the others is a difficult problem connected with the monogenesis or polygenesis (common or multiple origin) of writing. The Phoenician consonantal script provided the new typological pattern on which the Ugaritic and Old Persian systems were constructed, keeping only the outer likeness of the wedge form.   (J.Pl./Ed.)

Deciphering of Ugaritic

HIEROGLYPHIC WRITING

Hieroglyphic writing is a system that employs characters in the form of pictures. These individual signs, called hieroglyphs, may be read either as pictures, as symbols for pictures, or as symbols for sounds. The name hieroglyphic (from the Greek word for "sacred carving") is first encountered in the writings of Diodorus Siculus (1st century BC). Earlier, other Greeks had spoken of sacred signs when referring to Egyptian writing. Among the Egyptian scripts, the Greeks labeled as hieroglyphic the script that they found on temple walls and public monuments, in which the characters were pictures sculpted in stone. The Greeks distinguished this script from two other forms of Egyptian writing that were written with ink on papyrus or on other smooth surfaces. These were known as the hieratic, which was still employed during the time of the ancient Greeks for religious texts, and the demotic, the cursive script used for ordinary documents.

Hieroglyphic, in the strict meaning of the word, designates only the writing on Egyptian monuments. The word has, however, been applied for about 100 years to the writing of other peoples, insofar as it consists of picture signs used as writing characters. The name hieroglyphics is, for example, always used to designate the scripts of the Indus civilization and of the Hittites, who also possessed other scripts, in addition to the Mayan, the Incan, and Easter Island writing forms, and also the signs on the Phaistos Disk on Crete. Colloquially, the word hieroglyphics has been extended to mean any sort of illegible or barely legible writing.

Non-Egyptian hieroglyphic scripts

Because of their pictorial form, hieroglyphs were difficult to write and were used only for monument inscriptions. They were usually supplemented in the writing of a people

by other, more convenient scripts. Among living writing systems, hieroglyphic scripts are no longer used.

The rest of this section is concerned only with Egyptian hieroglyphic writing.

Development of Egyptian hieroglyphic writing. The most ancient hieroglyphs date from the end of the 4th millennium BC and comprise annotations to the scenes cut in relief—found on slabs of slate in chapels or tombs—that had been donated as votive offerings. Although by no means all of these earliest signs can be read today, it is nonetheless probable that these forms are based on the same system as the later classical hieroglyphs. In individual cases, it can be said with certainty that it is not the copied object that is designated but rather another word phonetically similar to it. This circumstance means that hieroglyphs were from the very beginning phonetic symbols. An earlier stage consisting exclusively of picture writing using actual illustrations of the intended words cannot be shown to have existed in Egypt; indeed, such a stage can with great probability be ruled out. No development from pictures to letters took place; hieroglyphic writing was never solely a system of picture writing. It can also be said with certainty that the jar marks (signs on the bottom of clay vessels) that occur at roughly the same period do not represent a primitive form of the script. Rather, these designs developed in parallel fashion to hieroglyphic writing and were influenced by it.

Improbability of relationship to cuneiform

It is not possible to prove the connection of hieroglyphs to the slightly older cuneiform characters used by the Sumerians in southern Mesopotamia. Such a relationship is improbable because the two scripts are based on entirely different systems. What is conceivable is a general tendency toward words being fixed by the use of signs, without transmission of particular systems.

Invention and uses of hieroglyphic writing. The need to identify a pictorial representation with a specific, unique event, such as a hunt or a particular battle, led to the invention of hieroglyphic writing. Hieroglyphs added to a scene signified that this illustration represented a particular war rather than an unspecified one or war in general. This new attitude toward time and toward history as unique events in time led to the invention of hieroglyphic writing. The system first appeared only in connection with relief depictions, which they explained by means of placenames. Beginning in the 1st dynasty (*c.* 2925–*c.* 2775 BC), images of persons were also annotated with their names or titles, a further step toward expressing individuality and uniqueness. The so-called annalistic tablets of the first two dynasties were pictorial representations of the events of a year with specifically designated personal names, places, and incidents. For example, accompanying a scene of the pharaoh's triumph over his enemies is the annotation "the first occasion of the defeat of the Libyans." Simultaneously, the writing of the Egyptians began to appear unaccompanied by pictorial representations, especially on cylindrical seals. These roller-shaped incised stones were rolled over the moist clay of jar stoppers. Their inscription prevented the sealed jar from being covertly opened and at the same time described its contents and designated the official responsible for it. In the case of wine, its origin from a specific vineyard and often also the destination of the shipment were designated, and, as a rule, so was the name of the reigning king.

From the stone inscriptions of the 1st dynasty, only individual names are known, these being mainly the names of kings. In the 2nd dynasty, titles and names of offerings appear, and, at the end of this dynasty, sentences occur for the first time. The discovery of a blank papyrus scroll in the grave of a high official, however, shows that longer texts could have been written much earlier; *i.e.,* since the early part of the 1st dynasty.
Relationship of writing and art. The form of these hieroglyphs of the archaic period (the 1st to 2nd dynasty) corresponds exactly to the art style of this age. Although definite traditions or conventions were quickly formed with respect to the choice of perspective—*e.g.,* a hand was depicted only as a palm, an eye or a mouth inscribed only in front view—the proportions remained flexible. The prerequisite of every writing system is a basic standardization,

but such a standardization is not equivalent to a canon (an established body of rules and principles) in the degree of stylistic conformity that it requires. A recognized canon of Egyptian hieroglyphic writing arose in the 3rd dynasty and was maintained until the end of the use of the script.

Formation of the standard and canon of Egyptian writing

In that hieroglyphic signs represented pictures of living beings or inanimate objects, they retained a close connection to the fine arts. The same models formed the basis of both writing and art, and the style of the writing symbols usually changed with the art style. This correspondence occurred above all because the same craftsmen painted or incised both the writing symbols and the pictures. Deviations from the fine arts occurred when the writing, which was more closely bound to convention, retained patterns that the fine arts had eliminated. The face in front view is an example of this. This representation, apart from very special instances, was eventually rejected as an artistic form, the human face being shown only in profile. The front view of the face was, however, retained as a hieroglyph from the archaic period to the end of the use of hieroglyphic writing. Similar cases involve the depiction of various tools and implements. Although the objects themselves fell out of use in the course of history—*e.g.,* clubs used as weapons—their representations, mainly misunderstood, were preserved in the hieroglyphic script. The hieroglyphs corresponding to objects that had disappeared from daily life were therefore no longer well known and were often distorted beyond recognition. But the style of representation in the hieroglyphs still remained closely bound to the art of the respective epoch. Thus there appeared taut, slender forms or sensuous, fleshy ones, or even completely bloated characters, according to the art style of the period.

Media for hieroglyphic writing. In historical times (2800 BC–AD 300), hieroglyphic writing was used for inscribing stone monuments and appears in Egyptian relief techniques, both high relief and bas-relief; in painted form; on metal, sometimes in cast form and sometimes incised; and on wood. In addition, hieroglyphs appear in the most varied kinds of metal and wood inlay work. All of these applications correspond exactly with the techniques used in fine art, and the same craftsmen who produced the works of art painted or incised the hieroglyphic inscriptions.

Hieroglyphic texts are found primarily on the walls of temples and tombs, but they also appear on memorials and gravestones, on statues, on coffins, and on all sorts of vessels and implements. Hieroglyphic writing was used as much for secular texts—historical inscriptions, songs, legal documents, scientific documents—as for religious subject matter—cult rituals, myths, hymns, grave inscriptions of all kinds, and prayers. These inscriptions were, of course, only a decorative monumental writing, unsuitable for everyday purposes. For popular use, hieratic script was developed, an abbreviated form of the picture symbols such as would naturally develop in writing with brush and ink on smooth surfaces like papyrus, wood, and limestone.

Subject matter of inscriptions

Writing and religion. The influence of religious concepts upon hieroglyphic writing was confined to two cases. In the 3rd millennium, certain signs were avoided or used in garbled form in grave inscriptions for fear that the living beings represented by these signs could harm the deceased who lay helpless in the grave. Among these taboo symbols were human figures and dangerous animals, such as scorpions and snakes. Second, in all periods and for all uses of the writing, symbols to which a positive religious significance was attached were regularly placed in front of other signs, even if they were to be read after them. Among these were hieroglyphs for God or individual gods, as well as those for the king or the palace. Thus, for example, the two signs, ⌐|| denoting the word combination "servant of God" (priest), are written so that the symbol for God, ⌐ , stands in front of that for servant, || , although the former is to be read last. Moreover, theology traced the invention of hieroglyphic writing back to the god Thoth, although this myth of its divine origin did not have an effect on the development of the script. In the late

*minatives.* By means of this rebus system in which letters and pictures were combined, the Egyptians could write a large number of the words of their language. But there remained a residue for which no drawable word with the same consonant framework presented itself—e.g., *nht* "strong." Here the Egyptians spelled out the word: for *n,* they had a sign, the water symbol (from the word *nwy* "flood"), and for *ht* they had the above-mentioned sign for wood, ⌄⌄⌄, so that they could now write *nht* as ⌄⌄⌄⌄.

Two additional reading aids that were quickly added to this system promoted distinctness and readability. For multiconsonant signs, one or more consonants, or in some cases all of them, were also written to serve as a phonetic complement. Thus there is ▷ for *mr* "to be ill," in which the owl (top, left) possesses the phonetic value *m* and the mouth (⌒) that of an *r.* In cases like this, the consonants, according to the conception of modern scholars, were written twice but were read only once. For the Egyptians, the single consonant signs were there simply as reading aids for the clarification of the word sign, the logogram. Accordingly, they wrote ⊝⌐, in which ⌄⌄ is complemented by the two signs

⊜, *h*, and ⌒, *t,* which appear after it.

In addition, determinatives—signs that do not represent a phonetic value but serve only to inform the reader as to the family of meanings to which the designated word belongs—were quickly formed out of these. The consonant combination *hti* "to engrave" has a knife written after it; on the other hand, *hti* "to retreat" has legs striding backward. Thus, these two words, otherwise written identically, are differentiated graphically as ⊝⌐⌄ and ⊝⌐⌃. In this manner, each Egyptian word possessed its own writing picture with which it was strictly associated. Grammatical endings were attached to this word picture and stood after the determinative. From the outset, therefore, Egyptian writing was a complete script; that is, it could unequivocally fix any word, including all derivations and all grammatical forms.

Summary of the types of signs. In summary, hieroglyphs can be separated into three groups, of which the first two render a phonetic value and the third represents mute reading aids: (1) ideograms, or signs that should be read as the word they represent—e.g., ⌄⌄, "branch"; (2) phonograms, or signs that do not refer back to the objects they represent but stand simply for one or more consonants—e.g., ⌁⌁⌁ as *n* and ⌄⌄ as *ht* in ⌄⌄⌄, *nht* "strong"; and (3) determinatives, which possess no phonetic value but which aid the reader by leading him to the correct interpretation of the meaning—e.g., ⌃ in ⊝⌐⌃, *hti* "to retreat."

Egyptian writing lacked punctuation in our meaning of the term. Line and stanza signs appeared only in certain literary texts.

Number of symbols. In the classical period of Egyptian writing, the number of hieroglyphs totaled approximately 700. Their number multiplied considerably in the late period (about 600 BC); this proliferation occurred because scholars constantly invented new forms or signs. The additional hieroglyphs were, however, always in accordance with the principles that had governed Egyptian writing from its beginnings. The hieroglyphic system remained flexible throughout all periods, always open to innovation, even though, as with every writing system, convention played a preponderant role.

Direction of the writing. The lines of hieroglyphs were written from right to left or, less frequently, from left to right. Vertical rows of signs could be placed next to horizontal rows, according to the particular demands of the architectural setting. The direction of the writing is immediately ascertainable because the signs almost always face the beginning of the row. Occasionally, some signs are turned around in the row, presumably so that two human figures can face one another and thus avoid standing with their backs toward each other. These rotations of signs are infrequent, however, and are found almost exclusively in the names of kings. Royal names were enclosed in a ring, the

---

period, Egyptian texts referred to hieroglyphic inscriptions as "writing of God's words"; earlier, in contrast, they were simply called pictures.

Literacy and knowledge of hieroglyphic writing. At all periods only a limited circle understood the script. Only those who needed the knowledge in their professions acquired the arts of writing and reading. These people were, for example, officials, doctors, and priests (insofar as they had to be able to read rituals and other sacred texts), as well as craftsmen whose work included the making of inscriptions. Under Greek and especially under Roman rule, the knowledge declined and was entirely confined to temples where priests instructed their pupils in the study **Decline** of hieroglyphic writing. From the time of the rule of **of hiero-** Ptolemies (305 to 30 BC), national consciousness became **glyphic** more and more narrowly bound up with religion, and for **writing** both the national consciousness and religion alike the tradition-filled hieroglyphic writing was an outward sign—in the fullest sense, a symbol. There was no lack of attempts to replace the hieroglyphic writing, cumbersome and ever more divergent from the spoken language, with the simpler and more convenient Greek script. Such experiments, however, remained ineffective precisely because of the emotional value that the old writing system had when the country was under the foreign domination of the Macedonian Greeks and the Romans.
Christianity and the Greek alphabet. The situation was altered with the conversion of the country to Christianity in the 2nd and 3rd centuries AD. The new religion fought against the Egyptian polytheism and traditions, and with its victory, the Greek script triumphed. From the beginning, Egyptian Christians used the Greek alphabet for writing their spoken Egyptian language. This practice involved enlarging the Greek alphabet with seven supplementary letters for Egyptian sounds not present in Greek. As a consequence, the knowledge of hieroglyphic writing quickly declined. The last evidence of the writing system is a rock inscription from the island of Philae, dating from Aug. 24, 394, from the reign of the emperor Theodosius I. The language as well as the writing system of the Egyptian Christians is called Coptic.

Characteristics of hieroglyphic writing. The system of hieroglyphic writing has two basic features: first, representable objects are portrayed as pictures (ideograms) and, second, the picture signs are given the phonetic value of the words for these represented objects (phonograms). At the same time, these signs are also written to designate homonyms, similar-sounding words. The writing disregards vowels and also, in earlier times, the semivowels *i, y,* and *w,* thus offering more possibilities for the transference of signs to words with identical consonant combina- **Ideograms** tions. For example, the sign for "wood" is written as a **and phono-** branch, ⌄⌄, which is pronounced with the consonants **grams** *h* and *t,* which occur in the Egyptian word for wood. Other words with the same series of consonants can also be written with the same basic sign—e.g., *ht* "after," *hti* "to retreat," or *hti* "to carve." Words that consisted of only one consonant, plus one or more vowels, supplied single consonant signs. The Egyptians, however, never reduced their writing to an alphabet by discarding the multiconsonant signs; rather, they retained clearly the form of the original words. When doubts occurred, as in the case of the three signs for the frequent consonant series *m + r* (the hoe, ▷, the chisel, ▯, and the pyramid, △), the plurality was used to make clear distinctions between words: all derivations from the stem *mr* "to love" were written with the hoe; those from the stem *mr* "to be ill," with the chisel; and those words related to pyramids with the sign for pyramid. Thus, two or more existing signs for the same sound or combination of sounds were retained and used in conscious distinction to promote easier readability. Although each sign originally had only one reading, occasional ambiguities did develop through the convergence of two symbols of similar form, such as those for the thighbone and the shankbone of an animal. A few signs, therefore, had two or, less commonly, three readings in classical Egyptian writing.
*Reading aids: spelling, phonetic complements, deter-*
Phonetic comple- ments

Invention of new signs

so-called cartouche; *e.g.,* ⬭⬭⬭⬭⬭ "Khufu," in Egyptian *Ḫwfw.* This ring, originally a rope, was supposed to protect the bearer of the enclosed name from injury and, in particular, from harmful magic.

Egyptian pedagogical traditions. To understand hieroglyphic writing, one must know about its tradition within Egypt. The Egyptian student of writing, who brought with him a knowledge of the spoken language as his mother tongue, began by learning the script picture corresponding to each word without having isolated its elements; *i.e.,* its individual signs. Through centuries this pedagogical tradition in the schools helped Egyptian words retain the original established spelling, with only minor—usually stylistic—changes, even when the phonetic form had radically changed. Hieroglyphic writing thus conceals historical sound changes.

Sound changes shown by misspellings The mistakes in hearing made by pupils in the writing schools have helped scholars to understand the phonetic changes that occurred in the development of the Egyptian language. When the pupil who was learning to write the hieroglyphic script did not recognize a word dictated to him, he wrote it badly—that is, just as he heard it. Because he had not yet learned to spell in the orthodox manner, what appeared on his papyrus was usually a word that sounded similar to the dictated but misunderstood term and whose word picture was familiar. Thus, although Egyptian writing was originally composed of symbols that represented a phonetic value, the system was transmitted in the form of word pictures—that is, closed or indivisible groups, generally of several signs per word.

Cryptographic hieroglyphic writing. That knowledge of the hieroglyphic system and the principles upon which it was devised had not become lost is attested by two phenomena: cryptography and the development of the hieroglyphic writing during the last millennium of its existence. From the middle of the 3rd millennium but more frequently in the New Kingdom (from *c.* 1539 BC), hieroglyphic texts are encountered that have a very strange appearance. The absence of familiar word groups and the presence of many signs not found in the canon characterize these texts at first glance as cryptographic, or secret, writing. This kind of hieroglyphic writing was probably intended as an eyecatcher, to entice people to seek the pleasure of deciphering it. Composed according to the original principles of the script, these inscriptions differed only in that certain features excluded when the original canon was formulated were now exploited. The new possibilities involved not only the forms of the signs but also their selection. For example, the mouth was not drawn in front view (⬭), as in the classical script, but in profile (⬭), although it had the same phonetic value. An example of a change in the choice of signs is the case in which a man carrying a basket on his head (⬭), a determinative without phonetic value in the classical script, was later to be read as *f* and was used in lieu of the familiar sign having this phonetic value, that of the horned viper. In the new selection of the sign, the phonetic value is obtained from the word *f3ỉ* "to carry" (neglecting its two weak consonants), in accordance with a principle that the inventors of the writing had applied in 3000 BC. These cryptographic inscriptions prove that alongside the method of instruction in the schools, which was based on memorization or recognition, not upon analytical understanding, Transmission of the hieroglyphic principles there was another tradition that transmitted knowledge of the basic principles of the hieroglyphic script. A command of the principles of hieroglyphics similar to that which the composers of the cryptic inscriptions had was presupposed for the puzzle-happy decipherers. Because the encoded texts often consisted of a petition by the inventor of the text to say a prayer on his behalf, the number of these decipherers must surely not have been small.

Growth of hieroglyphic writing during the 1st millennium BC. At about the middle of the 1st millennium BC, Egyptian writing experienced new developments and a revival of interest. Again the inscriptions abounded with new signs and sign groups unknown in the classical period, all generated according to the same principles as

the classical Egyptian script and the cryptographic texts. The writing of this late period was distinguished from the cryptograms in that this script, like every normal system of writing, developed a fixed tradition, being intended not to conceal but to be read easily, whereas the cryptography strove for originality.

Stages of hieroglyphic writing. The development of hieroglyphic writing thus proceeded approximately as follows: at first only the absolutely necessary symbols were invented, without a canonization of their artistic form. In a second stage, easier readability (*i.e.,* increased rapidity of reading) was achieved by increasing the number of signs (thereby eliminating some doubts) and by employing determinatives. Finally, after the second stage had endured, essentially unaltered, for about 2,000 years, the number of symbols increased to several thousand in about 500 BC. This rampant growth process occurred through the application of hitherto unused possibilities of the system. With the triumph of Christianity, the knowledge of hieroglyphic writing was extinguished along with the ancient Egyptian religion.

Tools. The tools used by the craftsmen for writing hieroglyphic symbols consisted of chisels and hammers for stone inscriptions and brushes and colours for wood and other smooth surfaces. Only for the cursive scripts, hieratic and demotic, were special materials developed. Leather and papyrus became writing surfaces, and the stems of rushes in lengths of six to 13 inches (15 to 33 centimetres), cut obliquely at the writing end and chewed to separate the fibres into a brushlike tip, functioned as writing implements. The split calamus reed was introduced into Egypt by the Greeks in the 3rd century BC. Development of special writing materials

Hieratic script. The Egyptian cursive script, called hieratic writing, received its name from the Greek *hieratikos* ("priestly") at a time when the script was used only for sacred texts. Everyday secular documents were written in another style, the demotic (Greek *dēmotikos,* "for the people" or "in common use") script.

Relation of hieratic to hieroglyphic script. The structure of the hieratic script corresponds with that of hieroglyphic writing. Changes occurred in the characters of hieratic simply because they could be written rapidly with brush or rush and ink on papyrus. In general, the picture form is not, or not easily, recognizable. Because their models were well known and in current use throughout Egyptian history, the hieratic symbols never strayed too far from them. Nevertheless, the system differs from the hieroglyphic script in some important respects:

1. Hieratic was written in one direction only, from right to left. In earlier times the lines had run vertically and later, about 2000 BC, horizontally. Subsequently the papyrus scrolls were written in columns of changing widths.

2. There were ligatures in hieratic so that two, but no more than two, signs could be written in one stroke.

3. As a consequence of its decreased legibility, the spelling of the hieratic script was more rigid than that of hieroglyphic writing. Variations from uniformity at a given time were minor; but, during the course of the various periods, the spelling developed and changed. As a result, hieratic texts do not correspond exactly to contemporary hieroglyphic texts, either in the placing of signs or in the spelling of words.

4. Hieratic used diacritical additions to distinguish between two signs that had grown similar to one another because of cursive writing. For example, the cow's leg received a supplementary distinguishing cross, because in hieratic it had come to resemble the sign for the leg of a man. Certain hieratic signs were taken into the hieroglyphic script.

All commonplace documents—*e.g.,* letters, catalogs, and official writs—were written in hieratic script, as were literary and religious texts. In the life of the Egyptians, hieratic script played a larger role than hieroglyphic writing and was also taught earlier in the schools. In offices, hieratic was replaced by demotic in the 7th century BC, but it remained in fashion until much later for religious texts of all sorts. The latest hieratic texts stem from the end of the 1st century or the beginning of the 2nd century AD. Role of hieratic in Egypt

Demotic script. Demotic script is first encountered at

the beginning of the 26th dynasty, in about 660 BC. The writing signs plainly demonstrate its connection with the hieratic script, although the exact relationship is not yet clear. The demotic characters are more cursive (flowing and joined) and thus more similar to one another, with the result that they are more difficult to read than are the hieratic forms. Countering this difficulty, there is less freedom for the writer's individual variations. It appears that demotic was originally developed expressly for government office use—that is, for documents in which the language was extensively formalized and thus well suited for the use of a standardized cursive script. Only some time after its introduction was it used for literary texts in addition to documents and letters; much later it was employed for religious texts also. The latest dated demotic text, from Dec. 2, 425, consists of a rock inscription at Philae. In contrast to hieratic, which is almost without exception written in ink on papyrus or other flat surfaces, demotic inscriptions are not infrequently found engraved in stone or carved in wood.

Alternative demotic spelling. The demotic system corresponds to the hieratic and hence also to the hieroglyphic system. Alongside the traditional spelling, however, there was another spelling that took account of the markedly altered phonetic form of the words by appropriate respelling. This characteristic applied especially to a large number of words that did not occur in the older language and for which no written form had consequently been passed down. The nontraditional spelling could also be used for old, familiar words.

Decipherment of hieroglyphic writing. With the possible exception of Pythagoras, no Greek understood the nature of hieroglyphic writing. The Greeks did not obtain guidance from their Egyptian contemporaries, some of whom even lived on Italian soil and wrote proper hieroglyphic inscriptions on Roman obelisks. Rather, the Greek tradition taught that hieroglyphs were symbolic Greek beliefs concerning hieroglyphic writing signs or allegories. The Egyptian-born Greek philosopher Plotinus interpreted hieroglyphic writing entirely from the viewpoint of his esoteric philosophy. Only one of the numerous works on the hieroglyphic script written in late antiquity has been preserved: the *Hieroglyphica* of Horapollon, a Greek Egyptian who probably lived in the 5th century AD. Horapollon made use of a good source, but he himself certainly could not read hieroglyphic writing and began with the false hypothesis of the Greek tradition, namely, that hieroglyphs were symbols and allegories, not phonetic signs.

The Middle Ages neither possessed any knowledge of hieroglyphic writing nor took any interest in it. But a manuscript of Horapollon brought to Florence in 1422 stirred great interest among the humanists. Without giving a thought to the possibility that ancient Egyptian originals might be available in Rome, Renaissance artists designed hieroglyphs after Horapollon's descriptions, as well as from their own imaginations. They used hieroglyphs as wisdom-laden symbols in architecture and also in drawings and paintings.

Kircher's attempts at decipherment. The great German scholar Athanasius Kircher (1602–80) began his attempts at decipherment with the Coptic language and with the correct hypothesis that the hieroglyphs recorded an earlier stage of this language. He also believed, again correctly, that the signs recorded phonetic values. In spite of this, he did not arrive at correct results—with the exception of a single character. This failure can be attributed not only to Kircher's erroneous assumption that the hieroglyphs must correspond phonetically to an alphabet but primarily to the fact that he was most interested in the Renaissance conception of a supposed symbolic meaning constituting the deeper significance of hieroglyphs. In his view, the phonetic value of the hieroglyphs was merely the commonplace, superficial part of the sign.

Discovery of the Rosetta Stone. Both the intellectual and the physical prerequisites for the deciphering of the hieroglyphic script first presented themselves at the end of the 18th century. By accident, a stone that exhibited three different scripts—hieroglyphic, demotic, and Greek—was discovered by members of Napoleon's expedition to Egypt in 1799 near Rashid (French Rosette; English Rosetta) on the Mediterranean coast. The Greek text stated clearly that the document set forth the same text in the sacred script, the folk or popular script, and Greek. The stone was promptly made known to all interested scholars. Important partial successes in the effort of deciphering the scripts were achieved by the Swede Johan David Åkerblad and by the English physicist Thomas Young, who mainly studied the demotic text, again beginning with the false hypothesis that the hieroglyphs were symbols. Young succeeded in proving that they were not symbols—at least Thomas Young's work that the proper names were not—and that the demotic and hieratic signs had come from the hieroglyphs. (He first published this result in the supplement to the 4th, 5th, and 6th editions of the *Encyclopædia Britannica*.) He was the first to isolate correctly some single-consonant hieroglyphic signs. But a wrong turn in the course of his investigations then prevented him from fully deciphering the writing.

Champollion's decipherment. This task of complete decipherment was first accomplished by the Frenchman Jean-François Champollion (1790–1832) in 1822, after long years of intensive work and many setbacks. His success was due to the recognition that hieroglyphic writing, exactly like the hieratic and demotic scripts derived from it, did not constitute a writing system of symbols but rather a phonetic script. He arrived at this breakthrough by an exact comparison of the three Egyptian forms of writing, as well as by reference to Coptic, the late phase of the Egyptian language that was written with the Greek alphabet and was thus directly readable. The Coptic language was also understood at that time. Starting, as had his predecessors, from Ptolemy and Cleopatra, both ring-enclosed royal names, and adding the hieroglyphic spelling of Ramses' name, Champollion determined, essentially correctly, the phonetic values of the signs. Soon after, he also learned to read and translate a large number of Egyptian words. Since then, precise research has confirmed and refined Champollion's approach and most of his results.

(He.B.)

Figure 2: *Egyptian hieroglyphs and their cursive equivalents.* The hieroglyphs depict (top to bottom): three fox skins tied together; a whip; a single-barbed harpoon; an adz at work on a block of wood; a stone jug with handle; a scribe's outfit; a roll of papyrus tied with a cord.

ALPHABETIC WRITING

An alphabet is a set of graphs, or characters, used to represent the phonemic structure of a language; in most

alphabets the characters are arranged in a definite order, or sequence (*e.g.,* A, B, C, etc.). In the usual case, each character represents either a consonant or a vowel, rather than a syllable or group of consonants and vowels. As a result, the number of characters required can be held to a relative few. A language that has 30 consonant sounds and five vowels, for example, needs at most only 35 separate letters. In a syllabary, on the other hand, the same language would require 30×5 symbols to represent each possible consonant-vowel syllable (*e.g.,* separate forms for *ba, be, bi, bo, bu; da, de, di,* and so on) and an additional five symbols for the vowels, thereby making a total of 155 individual characters. Both syllabaries and alphabets are phonographic symbolizations; that is, they represent the sounds of words rather than units of meaning.

The word alphabet, from the first two letters of the Greek alphabet—*alpha* and *beta*—was first used, in its Latin form, *alphabetum,* by Tertullian (2nd–3rd century AD), a Latin ecclesiastical writer and church father, and by St. Jerome. The classical Greeks customarily used the plural of *to gramma* ("the letter"); the later form *alphabētos* was probably adopted under Latin influence.

Theories of the origin of the alphabet. The evolution of the alphabet involved two important achievements. The first was the step taken by a group of Semitic-speaking people, perhaps the Phoenicians, on the eastern shore of the Mediterranean between 1700 and 1500 BC. This was the invention of a consonantal writing system known as North Semitic. The second was the invention, by the Greeks, of characters for representing vowels. This step occurred between 800 and 700 BC. While some scholars consider the Semitic writing system an unvocalized syllabary and the Greek system the true alphabet, both are treated here as forms of the alphabet.

Over the centuries, various theories have been advanced to explain the origin of alphabetic writing, and, since classical times, the problem has been a matter of serious study. The Greeks and Romans considered five different peoples as the possible inventors of the alphabet—the Phoenicians, Egyptians, Assyrians, Cretans, and Hebrews. Among modern theories are some that are not very different from those of ancient days. Every country situated in or more or less near the eastern Mediterranean has been singled out for the honour. Egyptian writing, cuneiform, Cretan, hieroglyphic Hittite, the Cypriot syllabary, and other scripts have all been called prototypes of the alpha-

bet. The Egyptian theory actually subdivides into three separate theories, according to whether the Egyptian hieroglyphic, the hieratic, or the demotic script is regarded as the true parent of alphabetic writing. Similarly, the idea that cuneiform may be the precursor of the alphabet may also be subdivided into those singling out Sumerian, Babylonian, or Assyrian cuneiform.

Among the various other theories concerning the alphabet are the hypotheses that the alphabet was brought by the Philistines from Crete to Palestine, that the various ancient scripts of the Mediterranean countries developed from prehistoric geometric symbols employed throughout the Mediterranean area from the earliest times, and that the proto-Sinaitic inscriptions (discovered since 1905 in the Sinai Peninsula) represent a stage of writing intermediate between the Egyptian hieroglyphics and the North Semitic alphabet. Another hypothesis, the Ugaritic theory, evolved after an epoch-making discovery in 1929 (and the years following) at the site of the ancient Ugarit, on the Syrian coast opposite the most easterly cape of Cyprus. Thousands of clay tablets were found there, documents of inestimable value in many fields of research (including epigraphy, philology, and the history of religion). Dating from the 15th and 14th centuries BC, they were written in a cuneiform alphabet of 30 letters.

The Early Canaanite theory is based on several undeciphered inscriptions also discovered since 1929 at various Palestinian sites; the writings belong in part to *c.* 1700 BC and are thus the earliest preserved documents in an alphabetic writing.

Despite the conflict in theories, scholars are generally agreed that, for about 200 years before the middle of the 2nd millennium BC, alphabet making was in the air in

the Syro-Palestinian region. It is idle to speculate on the meaning of the various discoveries referred to. That they manifest closely related efforts is certain; what the exact relationship among these efforts was, and what their relationship with the North Semitic alphabet was, cannot be said with certainty.

It can, however, be ascertained that the period from 1730 to 1580 BC in Syria, Palestine, and Egypt, during which there was an uprooting of established cultural and ethnic patterns in the Fertile Crescent, provided conditions favourable to the conception of an alphabetic script, a kind of writing that would be more accessible to larger groups of people, in contrast to the scripts of the old states of Mesopotamia and Egypt, which were confined largely to the priestly class. In default of other direct evidence, it is reasonable to suppose that the actual prototype of the alphabet was not very different from the writing of the earliest North Semitic inscriptions now extant, which belong to the last two or three centuries of the 2nd millennium BC. The North Semitic alphabet was so constant for many centuries that it is impossible to think that there had been any material changes in the preceding two to three centuries. Moreover, the North Semitic languages, based as they are on a consonantal root (*i.e.,* a system in which the vowels serve mainly to indicate grammatical or similar changes), were clearly suitable for the creation of a consonantal alphabet.

The inventor or inventors of the alphabet were, no doubt, influenced by Egyptian writing—perhaps also by other scripts. Indeed, it is probable that those who invented the alphabet were acquainted with most of the scripts current in the eastern Mediterranean lands at the time. Though the nationality of the inventor or inventors of the alphabet is unknown, it is now generally agreed that he or they belonged to the Northwest Semitic linguistic group, which includes the ancient Canaanites, Phoenicians, and Hebrews.

Originally, graphs were perhaps "motivated" pictorial signs that were subsequently used to represent the initial sound of the name of the pictured object. The North Semitic alphabet remained almost unaltered for many centuries. If the signs' external form (which, it must be emphasized, had no particular significance) is ignored and only their phonetic value, number, and order are considered, the modern Hebrew alphabet may be regarded as a continuation of the original alphabet created more than 3,500 years ago. The Hebrew order of the letters seems to be the oldest. The earliest evidence that the Hebrew alphabet was learned systematically was left in the form of a schoolboy's scribbling on the vertical face of the upper step of a staircase leading up to the palace at Tel Lakhish, in southern Israel. It includes the scratching of the first five letters of the early Hebrew alphabet in their conventional order, and it belongs to the 8th or 7th century BC.

Development and diffusion of alphabets. At the end of the 2nd millennium BC, with the political decay of the great nations of the Bronze Age—the Egyptians, Babylonians, Assyrians, Hittites, and Cretans—a new historical world began. In Syria and Palestine, the geographical centre of the Fertile Crescent, three nations—Israel, Phoenicia, and Aram—played an increasingly important political role. To the south of the Fertile Crescent, the Sabaeans, a South Arabian people (also Semites, though South Semites), attained a position of wealth and importance as commercial intermediaries between the East and the Mediterranean. To the west, seeds were sown among the peoples who later constituted the nation of Hellas—the Greeks. As a result, an alphabet developed with four main branches: (1) the so-called Canaanite, or main branch, subdivided into Early Hebrew and Phoenician varieties; (2) the Aramaic branch; (3) the South Semitic, or Sabaean, branch; and (4) the Greek alphabet, which became the progenitor of the Western alphabets, including the Etruscan and the Latin. The Canaanite and Aramaic branches constitute the North Semitic main branch.

The Canaanite alphabet. The two Canaanite branches may be subdivided into several secondary branches. First, Early Hebrew had three secondary branches—Moabite, Edomite, and Ammonite—and two offshoots—the script

of Jewish coins and the Samaritan script, still in use today for liturgical purposes only. Second, Phoenician can be divided into Phoenician proper and "colonial" Phoenician. Out of the latter developed the Punic and neo-Punic scripts and probably also the Libyan and Iberian scripts.

The term Early Hebrew is used to distinguish this branch from the later so-called Square Hebrew. The Early Hebrew alphabet had already begun to acquire its distinctive character by the 11th century BC. It was used officially until the 6th century BC and lingered on for several centuries more. In a stylized form it was used on Jewish coins from 135 BC to AD 132–135. The most ancient example of Early Hebrew writing is that of the Gezer Calendar of the period of Saul or David (*i.e., c.* 1000 BC). The oldest extant example of the Early Hebrew ABCs is the 8th–7th-century-BC schoolboy graffito mentioned above. A cursive style reached its climax in the inscriptions at Tel Lakhish, dating from the beginning of the 6th century BC. The Leviticus and other small Early Hebrew fragments found in the Dead Sea caves, which are probably from the 3rd century BC, are the only remains of what is considered to be the Early Hebrew book, or literary, hand.

<div style="margin-left:2em">Paramount importance of the Phoenician alphabet</div>

It is difficult to overestimate the importance of the Phoenician alphabet in the history of writing. The earliest definitely readable inscription in the North Semitic alphabet is the so-called Ahiram inscription found at Byblos in Phoenicia (now Lebanon), which probably dates from the 11th century BC. There is, however, no doubt that the Phoenician use of the North Semitic alphabet went further back. By being adopted and then adapted by the Greeks, the North Semitic, or Phoenician, alphabet became the direct ancestor of all Western alphabets. Only very few inscriptions have been found in Phoenicia proper. This rarity of indigenous documents is in contrast to the numbers of Phoenician inscriptions found elsewhere—on Cyprus, Malta, Sicily, and Sardinia, and in Greece, North Africa, Marseille, Spain, and other places.

The Aramaic alphabet. The adaptation of the North Semitic alphabet to the Aramaic language took place at some time in the 10th century BC, when Aramaic was spoken in several petty kingdoms in northern Mesopotamia and Syria, the most important of them being Dammeshek (Damascus). The process of the reestablishment of the Assyrian Empire and its hegemony over a good part of the Middle East began in the 9th century. One after another, the Aramaean states gave way under Assyrian onslaught. Dammeshek, the last survivor, fell in 732 BC. The end of Aramaean political independence marked the beginning of Aramaean cultural and economic supremacy in western Asia. The transplantation of masses of Aramaeans by the Assyrians, a political measure designed to break up military alliances, bore remarkable fruit. By the end of the 8th century BC the use of the Aramaic language and alphabet had become very widespread in Assyria itself; by the end of the following century all of Syria and a large part of Mesopotamia had become thoroughly Aramaized.

<div style="margin-left:2em">Aramaic inscriptions</div>

On the whole, the few early Aramaic inscriptions that have been found belong to the 9th, 8th, and 7th centuries BC. Inscriptions from the 6th and later centuries are numerous; the increase reflects the rapid spread of the Aramaic alphabet throughout the Middle East. Numerous Aramaic papyri and ostraca (inscribed pottery fragments) have been found in Egypt; the earliest of these can be dated to *c.* 515 BC, while the most famous are the Elephantine papyri, containing information of a religious and economic nature about a 5th-century Hebrew military colony in Egypt. Aramaic inscriptions have been found in northern Arabia, Palestine, Lycia, Cappadocia, Lydia, Cilicia, Assyria, and as far afield as Greece, Afghanistan, and India.

Almost as if by prearrangement, all of the alphabetic scripts west of Syria seem to have been derived, directly or indirectly, from the Canaanite alphabet, whereas the hundreds of alphabetic writings of the East apparently have sprung from the offshoots of the Aramaic alphabet. On the whole, the direct and indirect descendants of the Aramaic alphabet can be divided into two main groups: the scripts employed for Semitic languages and those adapted to non-Semitic tongues. With regard to the Semitic offshoots,

six separate alphabets may be discerned: the Hebrew, the Nabataean-Sinaitic-Arabic, the Palmyrene, the Syriac-Nestorian, the Mandaean, and the Manichaean. Some of these alphabets became links between the Aramaic alphabet and the numerous scripts used for the non-Semitic languages of Central, South, and Southeast Asia.

<div style="margin-left:2em">Adaptations of the Aramaic alphabet</div>

Among these scripts, which were directly or mainly indirectly adapted to non-Semitic languages from the Aramaic alphabet, are: (1) the Persian (Iranian) scripts known as Pahlavi, which were used for such writings as sacred (pre-Islāmic) Persian literature; (2) Sogdian, a script and language that constituted the lingua franca of Central Asia in the second half of the 1st millennium AD; (3) Kōk Turki, a script used from the 6th to the 8th century AD by Turkish tribes living in the southern part of central Siberia, in northwestern Mongolia, and in northeastern Turkistan (this alphabet was the prototype of the early Hungarian alphabet); (4) the alphabet of the Uighur, a Turkic-speaking people who lived in Mongolia and eastern Turkistan in the early 13th century; this script was adapted, with Tibetan influence, and adopted as the writing of the Mongol Empire (the so-called Kalika script); (5) the early scripts of the Mongols, including Kalmuck, Buryat (Buriat), Mongolian proper, and the allied Manchu alphabet.

The Aramaic alphabet was probably also the prototype of the Brāhmī script of India, a script that became the parent of nearly all Indian writings. Derived from the Aramaic alphabet, it came into being in northwest India. The Armenian and Georgian alphabets, created by St. Mesrob (Mashtots) in the early 5th century AD, were also based on the Aramaic alphabet.

The South Semitic alphabet. The South Semitic, or Sabaean, branch remained within the confines of the Arabian Peninsula for most of its history. It was in use at the beginning of the 1st millennium BC. The most that can be said about its origins is that it neither developed from nor directly depended upon the North Semitic alphabet. It may have been derived, ultimately, from the proto-Sinaitic script, with some influence from the North Semitic. Offshoots from the South Semitic branch include the Minaean, Himyaritic, Qatabanic, and Hadhramautic alphabets in southern Arabia, and Thamudene, Dedanite, and Safaitic alphabets in the northern part of the peninsula. Numerous inscriptions in these alphabets are the principal source for the study of those once-flourishing kingdoms, including Saba' (the biblical Sheba), relegated by the rise of Islām to the backwaters of history.

The Sabaean offshoot, a graceful and elegant script consisting of 29 letters, spread into Africa, where it became the progenitor of the Ethiopic alphabet; this in turn gave birth to the modern Amharic, Tigré, Tigrinya, and other alphabets of modern Ethiopia. These are the only South Semitic scripts still in use today.

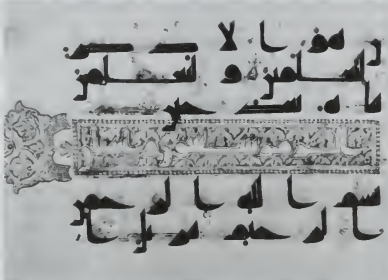
The Greek alphabet. As in so many other things, the importance of the ancient Greeks in the history of the alphabet is paramount. All of the alphabets in use in European languages today are directly or indirectly related to the Greek. The Greek achievement was to provide representations for vowel sounds. Consonants plus vowels made a writing system that was both economical and unambiguous (see above *History of writing systems*). The true alphabetic system has remained for 3,000 years, with only slight modifications, an unparalleled vehicle of expression and communication in and among the most diverse nationalities and languages. The Greek alphabet, created early in the 1st millennium BC, spread in various directions in Asia Minor, Egypt, Italy, and other places, but far and away its most important descendants were the Etruscan Latin and the Cyrillic alphabets.

Theories explaining diffusion. There is no complete agreement among scholars as to how or why certain alphabets have come to dominate much of the world. Some believe that diffusion is explained by the efficiency of the orthography; the Greek alphabet, capable of representing unambiguously a full range of meanings, was adopted throughout western Europe. Others hold that the alphabet follows the flag; that is, that the diffusion of an alphabet results from political and military conquests by the people who use it. Still others hold that the alphabet follows trade

or religion. A few examples may illustrate the point: (1) The Latin language and script were carried by Roman legionaries and imperial officers to all parts of the vast Roman Empire, particularly to the regions that were not Hellenized. In later centuries, however, churchmen and missionaries carried the Latin language and script still farther afield. The ascendancy of Latin led to the adoption of the Latin (Roman) alphabet by a large majority of nations; it became used for tongues of the most diverse linguistic groups, not only in Europe but in all other parts of the world as well. (2) Two alphabets, the Cyrillic and the Latin, are used for writing Slavic languages. Cyrillic is used by those Slavic peoples who accepted their religion from Byzantium, whereas Roman Christianity brought the use of the Latin alphabet to the Poles, Lusatians, Wends, Czechs, Slovaks, Slovenes, and Croats. (3) The Arabic alphabet is, after Latin, the most generally used in Asia and Africa. The rise of Islām in the 7th century AD and the tremendous Islāmic expansion and conquest carried the Islāmic holy book, the Qur'ān, written in the Arabic alphabet, over a vast area: the Middle East, North and Central Africa, South and Southeast Asia, and even southern Europe. The Arabic alphabet was, therefore, adapted to Semitic and Indo-European forms of speech, to Tatar-Turkish, Iranian, and Austronesian (Malayo-Polynesian) tongues, and to several African languages. (4) The movement eastward from India of the Indian Brāhmī-Buddhist alphabets was much more peaceful than that of the Arabic alphabet. These offshoots, which took root in Sri Lanka, Myanmar (Burma), Thailand, Cambodia, Laos, Vietnam, Indonesia, and the Philippines, were again the result of the spreading of a religion—Buddhism—but by missionaries and not by armies.

Major alphabets of the world. *Hebrew alphabet.* It is generally believed, in accordance with Jewish tradition, that the Early Hebrew alphabet was superseded in the Holy Land by the Aramaic alphabet during the Babylonian Exile (586–516 BC) and that the Aramaic script therefore became the parent of the Square Hebrew (in Hebrew *ketav merubaʿ* ["square script"] or *ketav ashuri* ["Assyrian writing"]). The theory may be only partly correct, because in the Holy Land the Early Hebrew alphabet was an object of such strong local attachment that for several centuries it was used side by side with the Aramaic script.

At any rate, there is little doubt that the Square Hebrew did derive from the Aramaic alphabet. A distinctive Jewish variety of the Aramaic alphabet that can be regarded as the Square Hebrew script can be traced from the 3rd century BC. It became standardized just before the Christian Era, and it was from this script that the modern Hebrew alphabet, in all its styles, eventually developed. The development was gradual and purely external (*i.e.*, in the shapes of the single letters); from the internal standpoint (*i.e.*, considering the phonetic values of the letters), there has been no development, though it must be borne in mind that for several letters (*waw, ḥet, tzade, qof, shin, sin,* and so forth) the exact original phonetic value is still uncertain. When the Square Hebrew alphabet became standardized, it took (at least, in its formal style and, much later, in its printed form) the form that, with insignificant changes, it has today. Minute rules laid down by the Talmud made further development of the Square Hebrew all but impossible.

In the Square Hebrew alphabet there are five letters—*kaf, mem, nun, pe,* and *tzade*—that have dual forms. That is, there is one character for initial or medial position and another for final position.


The Hebrew alphabet consists of 22 letters, all consonants, though four of them—*alef, he, waw,* and *yod*—are also employed to represent long vowels. The absence of vowel letters was not at first a problem, because Hebrew, like other Semitic languages, has consonantal roots, with vowels serving principally to denote inflections in nouns, moods of verbs, and other grammatical variations. As Hebrew speech passed out of daily use (being superseded by Aramaic, which became the vernacular of the Jews) and the knowledge of biblical Hebrew steadily declined, it became necessary to introduce some form of vocalic distinction so that the Bible could be read and explained

correctly. The three main vowel systems now extant are the Babylonian, the Palestinian, and the Tiberiadic; of these the latter is the most important and, indeed, the only one still in use. The Tiberiadic system consists of dots, combinations of dots, and small dashes.

Before the discovery of the celebrated Dead Sea Scrolls, several Square Hebrew inscriptions belonging mainly to the 1st century BC and the succeeding centuries were known; they were found on rocks, tombs, or ossuaries (depositories for the bones of the dead) and in synagogues and catacombs in Palestine, Syria, North Africa, and Italy. The biblical manuscripts, except for some fragments written on papyrus, belong to a much later date. The earliest fragment is the Nash papyrus of approximately the 1st century BC, now in the University of Cambridge Library. Many thousands of fragments of Hebrew biblical and other manuscripts, partly of the 7th and 8th centuries AD, were discovered in the Geniza, an archive in the old synagogue in Cairo.

The focus of scholarly interest during the late 1940s and the successive years was the sensational discovery of Hebrew biblical and nonbiblical scrolls in caves near the Dead Sea. The tens of thousands of fragmentary manuscripts, composing what are popularly called the Dead Sea Scrolls, may be divided into several groups, the oldest being a collection of biblical and other Hebrew manuscripts dating approximately from the 3rd century BC.

The theory that the alphabet follows religion

Standardization of Square Hebrew

Figure 3: Alphabet characters from North Semitic to modern Roman capital letters. The North Semitic, Greek, and Etruscan symbols do not always designate the same sound as the modern letters.

From D. Diringer, *The Alphabet: A Key to the History of Mankind*

In the more than bimillenary development of the Square Hebrew alphabet, four fundamental types can be noticed: (1) the square script, which evolved into the well-proportioned printing type of modern Hebrew (the majority of Dead Sea Scrolls are in this Square Hebrew script); (2) the medieval formal styles; (3) the rabbinic, also known as Rashi writing, which was the medieval book or literary hand; and (4) a cursive script or daily handwriting, which gave rise to many local varieties (Oriental, Spanish, Italian, Franco-German, and so on), of which the Polish-German became the current Hebrew handwriting of today. The Hebrew script has been adapted to some other languages, such as Arabic, Turkish (for the Karaite people of Crimea), and so forth, but particularly to German—hence, Yiddish—and Spanish—hence, Judeo-Spanish.

Arabic alphabet. The Arabic script descended from the Aramaic alphabet through the Nabataean and the neo-Sinaitic alphabets. After the Latin script, it is the most widely used form of alphabetic writing in the modern world. The Arab conquests of the 7th and 8th centuries AD brought the language and the script to the vast expanse of territory

Early Arabic writing.

extending from India to the Atlantic Ocean. The Arabic alphabet was adapted, with some necessary modifications, to such diverse languages as the Slavic tongues, Spanish, Persian, Urdu, Turkish, Hebrew, Berber, Swahili, Malay, Sudanese, and others.

The Arabic alphabet probably originated at some time in the 4th century AD, but the earliest extant Arabic writing is a trilingual inscription—Greek-Syriac-Arabic—of AD 512. The two principal types of Arabic writing, which developed quite early in the Muslim period, were the Kūfic, from the town of Kūfah in Mesopotamia, seat of a famous Muslim academy, and the *naskhī,* or Mecca-Medina script. Kūfic, a heavy, bold, and lapidary style, appeared toward the end of the 7th century AD. It was particularly suitable for writing on stone or metal, for painting or carving inscriptions on the walls of mosques, and for lettering on coins. Its letters are generally thick, squat, and unslanted. With the high development of Arabic calligraphy, Kūfic writing became an exceptionally beautiful script. From it there were derived a number of other styles, chiefly medieval, in North and Central Africa, Spain, and northern Arabia. Thereafter, it was virtually discontinued except for formal and monumental writing. Nevertheless, it was also used for writing precious manuscripts of the Qur'ān, many of which are extant today.

The *naskhī* style was from the very outset a more cursive form. It was always employed chiefly for writing on papyrus. In time, it evolved into innumerable styles and varieties, including the *ta'liq,* the *riqa',* the *divani,* the *thuluth,* and the *syakat,* and became the parent of the modern Arabic writing.

Like other Semitic scripts, Arabic is written from right to left. Its alphabet contains 28 consonantal letters, 22 being directly derived from the Aramaic-Nabataean branch of the North Semitic alphabet and six being new additions; three of the letters—*alif, wāw,* and *yā*—are also used as long vowels.

The written letters undergo a slight external change according to their position within a word. When they stand alone or occur at the end of a word, they ordinarily terminate in a bold stroke; when they appear in the middle of a word, they are ordinarily joined to the letter following by a small, upward curved stroke. With the exception of six letters, which can be joined only to the preceding ones, the initial and medial letters are much abbreviated, while the final form consists of the initial form with a triumphant flourish. The essential part of the characters, however, remains unchanged. On the whole, the evolution of the forms of the Arabic letters was the most rapid of all the branches of alphabetic writing.

Although the absence of vowel letters was not strongly felt in Arabic (as in Hebrew and other Semitic languages), for teaching purposes and for correct reading of the Qur'ān, the use of diacritical marks (including signs for short vowels, which are sometimes used in conjunction with the letters *alif, wāw,* and *yā*) was introduced in Basra in the early 8th century. The practice was probably borrowed from the Syriac script. It not only provides vowel sounds but also distinguishes different consonants; diacritical points are also used as endings in the inflection of nouns and the moods of verbs. These marks—there are three of them—are written above or below the consonants (preceding the vowel), while a sign called *sukūn* indicates the absence of a vowel. Thus, there are, on the whole, a great number of diacritical points; these form a peculiar characteristic of this writing form.

Indian alphabets. The Aramaic alphabet was probably the prototype of the Brāhmī script of India, the ancestor of all Indian scripts. The transmission probably took place in the 7th century BC. Adapting the Aramaic script to the Indo-Aryan tongue of India was by no means simple or straightforward. The shapes of many Brāhmī letters show clear Semitic influence; moreover, the Brāhmī script was originally written from right to left. It is obvious, however, that on the whole it was the idea of alphabetic writing that was transmitted and that the fully developed Brāhmī writing was the outcome of the brilliant philological and phonological elaboration of the scientific Indian school.

During the 5th century BC the second of the prototypal

Gupta
writing
in India

Indian alphabets—the Kharoṣṭhī script—came into being in northwest India (which was then under Persian rule). Although the origin of Brāhmī is still uncertain and hotly discussed, it is commonly accepted that the Kharoṣṭhī alphabet is a direct descendant from the Aramaic alphabet. Moreover, the direction of writing in Kharoṣṭhī script is as in Aramaic, from right to left, and there is also a likeness of many signs having similar phonetic value.

In the later centuries of its existence, Brāhmī gave birth to eight varieties of script. Three of them—the early and late Maurya and the Śuṅga—became the prototypes of the North Indian subdivision of the Brāhmī script in the 1st centuries BC and AD. Out of this North Indian subdivision there arose the Gupta, which was employed from the 4th to the 6th century AD and became the ancestor of the great majority of Indian scripts.

The western variety of the Gupta spread into eastern (or Chinese) Turkistan, where it was adopted for a number of languages, including the recently discovered Turfanian and Kuchean (Tocharian A and B), and where it strongly influenced the invention or revision of the Tibetan script (AD 639). There were two main offshoots of the Tibetan writing: the 'Phags-pa, adapted to the Chinese and Mongolian languages in 1272; and the Lepchā, which arose in the beginning of the 18th century.

Much more important was the Siddhamātṛka script, developed during the 6th century AD from the western branch of the eastern Gupta character. The Siddhamātṛka became the ancestor of the Devanāgarī, or Nāgarī, script (Sanskrit *deva* ["divine"], *nāgarī* ["script of the city"]), which is the script used for Sanskrit. It is, therefore, the most important Indian script. Consisting of 48 signs (14 vowels and diphthongs and 34 basic consonants), it is the common means of communication among the learned throughout India. The Devanāgarī developed in the 7th to 9th centuries and has remained since then essentially unaltered.

From the Devanāgarī writing as used in eastern India in the 11th century, there developed the proto-Bengali and the early Nepālī, or Newārī, scripts, from which the many scripts employed at present in northern India and Bangladesh descended (*e.g.*, the Bengali, Oṛiyā, Manipurī, Assamese, Gujarātī, and Hindi scripts and the various Eastern Hindi local scripts).

In northwestern India several other scripts are employed. The Śāradā script, a descendant of the western type of the Gupta character, originated in the 8th century and is still employed for Kashmiri. In addition, there are the several varieties of the Ṭākrī, used by the people living on the lower ranges of the western Himalayas; the Dogrī, used for a dialect of Punjābī; the Laṇḍā, the national alphabet of Punjābī, which has many varieties and is used mainly by shopkeepers of Punjab and Sindh; and the Gurmukhī script, the characters of the Sikh scriptures.

In South India, which is inhabited by peoples speaking Dravidian languages, several other scripts are used, of which the Kannaḍa, or Kanarese, the Telugu, the Grantha, the Tulu-Malayālam, the Tamil, and the Vaṭṭeluttu are the most important.

Long before the existence of the Gupta script, the Brāhmī script had already begun its eastward movement. The Indo-Aryan migration in the 5th century BC to the island now known as Sri Lanka had set the stage there, and the earliest Brāhmī inscriptions in Sri Lanka can be dated to the 3rd century BC. Most dramatic of all, however, was the expansion of Buddhism from India into what is now Sri Lanka, Myanmar, Thailand, Cambodia, Laos, Vietnam, Malaysia, and Indonesia. As already mentioned, unlike the conquests of Islām, this was a peaceful movement; its "soldiers" were Buddhist monks, political independents who built an empire founded on the cultural and spiritual community of peoples. Among their many achievements, these monks brought into being offshoots from the Brāhmī script, principally from its South Indian varieties, throughout the vast extent of territory from India itself to the Philippines. Thus arose the many scripts of Southeast Asia, from the Cham writing of Cambodia to the Kavi character of Java and its Sumatran offshoots and the Tagalog writing of the Philippines.

All these Indian and Southeast Asian scripts involve types of semi-syllabaries rather than alphabets. They consist of vowels and diphthongs and basic consonants (*i.e.*, consonants followed by a short *a*); there are no pure consonants (*i.e.*, consonants written by themselves).

Greek alphabet. The Greek alphabet derived from the North Semitic script in the 8th century BC. The direction of writing in the oldest Greek inscriptions—as in the Semitic scripts—is from right to left, a style that was superseded by the boustrophedon (meaning, in Greek, "as the ox draws the plow"), in which lines run alternately from right to left and left to right. This change occurred approximately in the 6th century BC. There are, however, some early Greek inscriptions written from left to right, and after 500 BC Greek writing invariably proceeded from left to right.

The letters for *b, g, d, z, k, l, m, n, p, r,* and *t,* which are sounds common to the Semitic and Greek languages, were taken over without change. The principal Greek change arose in applying a script developed to represent a Semitic

language, in which vowel sounds are of minor importance to the identity of a word, to a language in which such vowel differences are crucial to the identity of a word. In Greek, /kat/, /kit/, and /kot/ are entirely different words, while in Semitic languages they would be the same word in different grammatically inflected forms. The Greek addition of vowels to the alphabet to make it an analogue of the sound pattern produced a writing system that was both manageable and accurate (see above *History of writing systems*). The different ways in which these adaptations were carried out allow the two main branches of the early Greek alphabet—the eastern and the western—to be distinguished. These again subdivided, each into secondary branches. Within this general grouping there were many local peculiarities, but the differences between all these local alphabets involved variations in detail rather than essential structure.

The eastern and western subdivisions were the two principal branches of the early Greek alphabet. The Ionic alphabet was the most important of the eastern variety, which also included the Greek alphabets of Asia Minor and the adjacent islands, of the Cyclades and Attica, of Sicyon and Argos, and of Megara, Corinth, and the Ionian colonies of Magna Graecia. A secondary branch of the eastern subdivision was made up of the alphabets used on the Dorian islands of Thera, Melos, and Crete. The alphabets of Euboea (Chalcidian), Boeotia, Phocis, Locris, Thessaly, the Peloponnesus (except its northeastern part), and of the non-Ionian colonies of Magna Graecia belonged to the western subdivision. It is a controversial point whether the eastern or the western branch was the earlier in time, whether there was any derivative link between one and the other, or whether they represent two quite independent adaptations of the Semitic alphabet. The latter alternative seems rather improbable.

Gradually, the Greek local alphabets became more and more similar. In 403 BC the Ionic alphabet of Miletus was officially adopted in Athens and later also in the other states. By the middle of the 4th century BC almost all the local alphabets had been replaced by the Ionic, which became the common, classical Greek alphabet of 24 letters.

After this time the development of the Greek alphabet was almost wholly external, in the direction of greater utility, convenience, and, above all, beauty. The classical style was retained as a monumental script at the same time that more cursive forms grew up for writing on such surfaces as parchment, papyrus, and wax. The classical letters were also retained as the capital letters in the modern print (though some of the capitals in modern Greek handwriting are borrowed from the Latin alphabet). On the other hand, the classical Greek alphabet also evolved into the Greek uncials, the cursive, and the minuscule script. (Uncial letters were somewhat rounded and separated versions of capital letters or cursive forms; minuscule letters developed from cursive writing and have simplified, small forms.) Until about AD 800 the uncials were used as a book hand; later the minuscule script was employed for the same purpose. The cursive scripts evolved into the modern Greek minuscule.

In the middle of the 3rd century BC, the Greek scholar Aristophanes of Byzantium introduced the three accents—acute, grave, and circumflex—that were thereafter used to assist students, particularly foreigners, in the correct pronunciation of Greek words; these continue to be used in most Greek texts printed today. Originally, these marks indicated tone or pitch, not stress.

Countless inscriptions have been discovered all over the Hellenic and Hellenistic world and beyond. They include official decrees, annals, codes of law, lists of citizens, civic rolls, temple accounts, votive offerings, ostraca (fragments of pottery), sepulchral inscriptions, coins, lettering on vases, and so forth. These, along with many thousands of Greek manuscripts, both ancient and medieval, serve as sources for the studies known as Greek epigraphy and Greek paleography and are of untold importance for all branches of ancient history, philology, philosophy, and other disciplines.

The most direct offshoots from the Greek alphabet were those adapted to the languages of the non-Hellenic peoples of western Asia Minor in the 1st millennium BC: the scripts of the Lycians, Phrygians, Pamphylians, Lydians, and Carians. The first three of these were derived directly from the Greek; the Lydian and Carian were strongly influenced by it. The Coptic alphabet was the other non-European offshoot from the Greek and the only one used in Africa. Twenty-four of its 31 letters were borrowed from the Greek uncial writing, and seven were taken over from a particularly cursive variety of the Egyptian demotic writing; the demotic letters were used to express Coptic sounds not existing in the Greek language.

More significant, however, were the European offshoots. In Italy, two alphabets derived directly from the Greek: the Etruscan and the Messapian (Messapic). The Messapii were an ancient tribe who inhabited the present Apulia (in southern Italy) in pre-Roman times; their language is presumed to belong to the Illyrian group. More than 200 Messapian inscriptions have been discovered. In southeastern Europe there were three offshoots from the Greek alphabet: the Gothic, Cyrillic, and Glagolitic alphabets.

The Gothic alphabet, not to be confused with the so-called Gothic script (a variety of the Latin alphabet), was a script created by the Gothic bishop Ulfilas (or Wulfila), who died *c.* AD 382. The script consisted of 27 letters, of which some 19 or 20 were taken over from the Greek uncial script. Ulfilas translated the Bible into Gothic; of this translation, some fragments are extant in manuscripts of the 5th and 6th centuries. The most important manuscript is the Codex Argenteus, preserved in Uppsala, Swed.

Cyrillic and Glagolitic alphabets. The two early Slavic alphabets, the Cyrillic and the Glagolitic, were invented by St. Cyril, or Constantine (*c.* 827–869), and St. Methodius (*c.* 825–884). These men were Greeks from Thessalonica who became apostles to the southern Slavs, whom they converted to Christianity. An early tradition, in attributing the invention of an early Slavic writing to Cyril, does not indicate whether his contribution was the Cyrillic or the Glagolitic. It is just possible that both alphabets were invented by him. The earliest dated Old Slavic documents belong to the late 10th and the 11th centuries. The Cyrillic and the Glagolitic alphabets differed widely in the form of their letters, in the history of their development, and partly also in the number of the letters, but they were alike in representing adequately the many sounds of Slavic.

The Cyrillic alphabet was based on the Greek uncial writing of the 9th century. It originally had a total of 43 letters; the two Hebrew letters *tzade* and *shin* were transformed into the Cyrillic letters for the sounds *ch, sh,* and *shch.* The modern forms of this alphabet have fewer letters. Glagolitic writing consisted of 40 letters, externally very unlike either the Greek or Cyrillic scripts.

Cyrillic became, with slight modification in each case, the national script of the Bulgarians, Serbs, Russians, Belorussians, and Ukrainians. (The other Slavic peoples—the Slovenes, Croats, Czechs, Slovaks, Wends, Lusatians, and Poles—use the Latin alphabet.) In the Balkan Peninsula a single language, Serbo-Croatian, is written in Cyrillic by the Greek Orthodox Serbs and in the Latin alphabet by the Roman Catholic Croats. For a time, Cyrillic was also adapted to the Romanian language, and in recent times, through the medium of Russian script, it became the writing of a number of Finno-Ugric languages (Komi, Votyak, Mordvinian, Vogul, Ostyak, etc.), Turco-Tatar languages (Chuvash, Turkmenian, Azerbaijanian, etc.), Iranian languages (Ossetic, Kurdish, Tajiki), and Caucasian languages (Abkhaz, Circassian, Avar, etc.).

The history of the Glagolitic alphabet is particularly connected with the religious history of the Slavic peoples of southwest central Europe and the western Balkan Peninsula. In the second half of the 9th century it was introduced, together with the Slavonic liturgy, into the Moravian kingdom, but with the banning of this liturgy by the pope it disappeared from Moravia. It was, however, accepted (also with the Slavonic liturgy) in Bulgaria and Croatia and spread along the Dalmatian coast southward into Montenegro and westward into Istria. Although the Glagolitic script soon disappeared among the Greek Orthodox Slavic peoples because of the victory of the Cyrillic, it continued, notwithstanding the opposition of the higher

Roman Catholic authorities, to be employed among the Roman Catholics of the western Balkan Peninsula together with the Slavonic liturgy and finally succeeded in obtaining the special license of the pope. It is still employed in the Slavonic liturgy in some Dalmatian and Montenegrin communities; the inhabitants of these places are the only Roman Catholics to use the Slavonic liturgy. The earliest preserved Glagolitic secular document dates from 1309. Glagolitic had a short flourishing period in the 16th and 17th centuries.

Etruscan alphabet. The Etruscans, a highly civilized people who were the ancestors of the modern Tuscans and the predecessors of the Romans, inhabited what is now Tuscany in central Italy; their language, still mainly undeciphered, has come down in more than 11,000 inscriptions, the earliest being the 8th-century-BC Marsiliana Tablet, preserved in the Museo Archeologico in Florence. This is also the earliest preserved record of a Western alphabet. The early Etruscan alphabet, unlike any early Greek alphabet found in the Greek inscriptions, contains the original—the prototype—Greek alphabet, consisting of the 22 North Semitic letters, with the phonetic values given to them by the Greeks, and the four additional Greek letters at the end of the alphabet. The Etruscans introduced various changes in their script, and several features in the modern alphabets can be attributed to the influence of the ancient Etruscans. An example is the phonetic value of /k/ for the letters *c, k,* and *q*. Like the Semitic and the early Greek alphabets, Etruscan writing nearly always reads from right to left, though a few inscriptions are in boustrophedon style. The probable date of the origin of the Etruscan alphabet is the late 9th or early 8th century BC.

About 400 BC the "classical" Etruscan alphabet took its final form of 20 letters—four vowels and 16 consonants. Because the voiced and voiceless sounds *b* and *p, d* and *t, g* and *k* were not differentiated in the Etruscan language, the letters *b* and *d* never appear in pure Etruscan inscriptions, and after the disappearance of *k* and *q,* the letter *C* was employed for *g* and *k*.

The Etruscan alphabet had many varieties and several offshoots. Among the offshoots, apart from the Latin, were many alphabets used by Italic populations of pre-Roman Italy and by non-Italic tribes (*e.g.,* the Piceni).

Latin alphabet. The adaptation of the Etruscan alphabet to the Latin language probably took place some time in the 7th century BC. From this century there is a gold brooch known as the Praeneste Fibula (preserved in the Museo Preistorico Etnografico Luigi Pigorini in Rome). The inscription, written in an early form of Latin, runs from right to left and reads clearly: *manios: med:fhefhaked:numasioi,* which in classical Latin is *Manius me fecit Numerio* ("Manius made me for Numerius").

Dating from the end of the 7th or the beginning of the 6th century BC is a famous cippus (small pillar) from the Roman Forum; it is inscribed vertically on its four faces, in boustrophedon style. Another inscription, probably of the 6th century BC, is known as that of the Duenos Vase and was found in Rome, near the Quirinal Hill. It is also written from right to left. Some Sabine inscriptions belong to the 5th or the 4th century BC. There are also a few inscriptions belonging to the 3rd and 2nd centuries BC.

The Roman capital letters, a form of writing that was used under the empire with unparalleled effectiveness for monumental purposes, became a byword for precision and grandeur, despite a very unprepossessing beginning. Indeed, for the first six centuries of its existence, Roman writing was relatively unimpressive. Only with the advent of the 1st century BC were there signs of magnificence to come.

An opinion that used to be commonly held, and still is held by many, is that the Latin alphabet was derived directly from the Greek in a form used by Greek colonists in Italy. The theory rested on an assertion that the Latin alphabet corresponds to the Chalcidian variety of the western group of Greek scripts employed at Cumae in Campania, southern Italy. This theory is unlikely; indeed, as already mentioned, the Etruscan alphabet was the link between the Greek and the Latin. For instance, the

most interesting feature in the inscription of the Praeneste Fibula is the device of combining the letters *f* and *h* to represent the Latin sound of *f*. This was one of the Etruscan ways of representing the same sound. Also, most of the Latin letter names, such as *a, be, ce, de* for the Greek *alpha, beta, gamma, delta,* and so on, were taken over from the Etruscans.

Runic and ogham alphabets. Runes, in all their varieties, may be regarded as the "national" script of the ancient North Germanic tribes. The origin of the name rune (or runic) is probably related to the fact that the ancient Germanic tribes, like all primitive peoples, attributed magic powers to the mysterious symbols scratched on armour, jewels, tombstones, and so forth. This is given credence by two related Germanic forms that mean "mystery, secret, secrecy": the Old Germanic root *ru-* and the Gothic *runa*. The most interesting runic inscriptions are those that were cut for magical purposes and those that appeal to deities.

The origin of the runes offers many difficult problems and has been hotly argued by scholars and others. The theory of the *Urrunen* (forerunners of the runes), a supposed prehistoric north Germanic alphabetic script, holds that it is the parent not only of the runes but also of all the Mediterranean alphabets, including the Phoenician. This belief, based on racial and political grounds, need not be seriously considered. Some scholars propounded the 6th century BC Greek alphabet as the prototype of the runes; others have suggested the Greek cursive alphabet of the last centuries BC. Several eminent scholars have proposed the Latin alphabet as the source of the runes. The most probable theory, supported recently by many scholars, is that the runic script derived from a North Etruscan, Alpine alphabet. In that case, it is very probable that it originated about the 2nd century BC or a little later.

It is still unknown whether the runes were originally employed mainly for magical purposes, as suggested by the name *runa,* or as a usual means of communication. The earliest extant runic inscriptions, numbering over 50, come from Denmark and Schleswig and date from the 3rd to the 6th century AD. About 60 inscriptions from Norway date from the 5th to the 8th century, slightly later than the continental ones. There are also about 50 Anglo-Saxon runic inscriptions extant, including the Franks Casket (about AD 650–700); the right side of the casket is in the Museo Nazionale del Bargello, in Florence, and the rest is in the British Museum. The largest number of inscriptions, about 2,500, come from Sweden; most of these date from the 11th and 12th centuries AD.

There is no certain evidence of wide literary use of runes in early times, but some scholars hold that the runic writing was widely employed for all kinds of secular documents, such as legal provisions, contracts, genealogies, and poems. The known manuscripts are, however, rare and relatively late. The gradual displacement of the runes coincided with the increasing influence of the Roman Catholic Church. The runic scripts lingered on for a long time after the introduction of Christianity, however; indeed, the use of runes for charms and memorial inscriptions lasted into the 16th or even the 17th century.

The ogham alphabet was restricted to the Celtic population of the British Isles. There are over 375 known inscriptions: 316 of them have been discovered in Ireland, chiefly in the southern counties, with only 55 from the northern counties; 40 inscriptions have been discovered in Wales; two come from Devon; and one from Cornwall. One inscription was discovered at Silchester in southern England. About 10 come from the Isle of Man, and a few from Scotland. The Welsh inscriptions are usually bilingual, Latin-Celtic. With one exception, the Irish records are in ogham alone. Most peculiar is the runic-oghamic inscription from the Isle of Man (the runes being a kind of "secret" writing and the oghams being a cryptic script). The distribution of the ogham inscriptions, combined with their language and grammatical forms, point to South Wales or southern Ireland as their place of origin and to the 4th century AD as the date of their origin.

The ogham character was used for writing messages and letters (generally on wooden staves), but sometimes it was

From D. Diringer, *The Alphabet A Key to the History of Mankind*

also written on shields or other hard material and was employed for carving on tombstones. The oghams formed a cryptic script, and there were several varieties, such as wheel oghams, bird oghams, tree oghams, hill oghams, church oghams, colour oghams, and others. The main ogham alphabet consisted of 20 letters represented by straight or diagonal strokes, varying in number from one to five and drawn or cut below, above, or right through horizontal lines, or else drawn or cut to the left, right, or directly through vertical lines. The ogham alphabet was divided into four groups (*aicme*), each containing five letters. Oghams were employed during the Middle Ages; the 14th-century *Book of Ballymote* reproduces the earliest keys for translation. In many cases the ogham inscriptions run upward.

Pictish oghams Several ogham inscriptions known as the Pictish oghams were found in western Scotland, on the small island of Gigha off the western coast, in Argyll, in northeastern Scotland, and on the northern isles, such as the Shetland Islands. They either belong to the same type as the Irish and Welsh oghams or are written in another ogham variety.

Later development of the Latin alphabet. As already mentioned, the original Etruscan alphabet consisted of 26 letters, of which the Romans adopted only 21. They did not retain the three Greek aspirate letters (*theta, phi,* and *chi*) in the alphabet because there were no corresponding Latin sounds but did employ them to represent the numbers 100, 1,000, and 50. Of the three Etruscan *s* sounds, the Romans kept what had been the Greek *sigma*. The symbol that represented the aspirate later received the shape *H* as it did in Etruscan. *I* was the sign both of the vowel *i* and the consonant *j*. *X* was added later to represent the sound *x* and was placed at the end of the alphabet. At a later stage, after 250 BC, the seventh letter, the Greek *zeta*, was dropped because Latin did not require it, and a new letter, *G*, made by adding a bar to the lower end of *C*, was placed in its position.

After the conquest of Greece in the 1st century BC, a large number of Greek words were borrowed by the

Latin language. At that time the symbols *Y* and *Z* were adopted from the contemporary Greek alphabet, but only to transliterate Greek words; hence, they do not appear in normal Latin inscriptions. They were placed at the end of the alphabet, and the Latin script thus became one of 23 symbols.

A few permanent additions or, rather, differentiations from existing letters occurred during the Middle Ages, when the signs for *u* and *v*, and *i* and *j*, previously written interchangeably for either the vowel or the consonant sound, became conventionalized as *u* and *i* for vowels and *v* and *j* for consonants. *W* was introduced by Norman scribes to represent the English sound *w* (a semivowel) and to differentiate it from the *v* sound.

The connection of the capital letters of modern writing with the ancient Semitic-Greek-Etruscan-Latin letters is evident even to a layman. The connection of the minus- Derivation of majus- cules (*i.e.,* the small letters) with the ancient Latin letters cules and is not as evident, but in fact both the majuscules and the minuscules minuscules descended from the same ancient Latin alpha- from Latin bet. The different shapes of the small letters are the result alphabet of a transformation of the ancient letters by the elimination of a part of the letter—as, for instance, *h* from *H* and *b* from *B*—or by lengthening a part of it—for instance, *d* from *D*. Moreover, the change of the Latin writing into the modern script was induced by the nature of the tool, primarily the pen, and the material of writing, mainly papyrus and parchment, and, from the 14th century onward, also paper. It was the pen, with its preference for curves, that eliminated the angular forms; it was the papyrus, and still more the parchment or vellum, and, in modern times, paper, that made these curves possible.

In ancient times the minuscule did not exist, but there were several varieties of the capital and the cursive scripts. There were three varieties of the capitals: the lapidary capitals (used mainly on stone monuments); the elegant book capitals, somewhat rounded in shape; and the rustic capitals, which were less carefully elaborated than the lapidary script and not as round as the book capitals but

Figure 6: Comparison of Latin, runic, Greek, Cyrillic, and Glagolitic alphabets.

more easily and quickly written. In everyday life the cursive script—*i.e.,* the current hand—was developed with continuous modifications for greater speed. There were several varieties of it, such as those of Pompeii and Alburnus Major (a town in ancient Dacia, modern Roşia Montană, Romania). Between the monumental and the cursive scripts there was a whole series of types that had some of the peculiarities of each group. There were lapidary mixed scripts and book semicursive scripts, and there was the early uncial, or rather semiuncial, script of the 3rd century AD, which seems to have developed into the beautiful uncial script.

When the various European countries had shaken off the political authority of Rome and the learned communities had been dissolved and their members scattered, a marked change took place in the development of the Latin literary, or book, hand. Several national hands, styles of the Latin cursive, assumed different features. There thus developed on the European continent and in the British Isles the five basic national hands, each giving rise to several varieties: Italian, Merovingian in France, Visigothic in Spain, Germanic, and Insular or Anglo-Irish hands. At the end of the 8th century the Carolingian (Caroline) hand developed and, after becoming the official script and literary hand of the Frankish Empire, developed as the main book hand of western Europe in the following two centuries. The combination of the majuscules, or capital letters, and minuscules, or small letters, can be attributed mainly to the Carolingian script.

In the course of the next centuries, various book hands or chart hands and other cursive scripts developed from the Carolingian style. In the late 12th century and during the next two centuries the letters gradually became angular in shape; this resulted from the pen being held in a position that made a slanting stroke. The new hand, termed black letter or Gothic, was employed mainly in northwestern Europe, including England, until the 16th century. It is still used, though rarely, in Germany, where it is called Fraktur script.

In Italy the black letter was also used, but the Italians preferred a rounder type, called *littera antiqua,* "old letter." During the 15th century the round, neat, humanistic or Renaissance hand was introduced in Florence and was employed for literary productions, while the needs of everyday life were met by an equally beautiful, though not as clearly legible, cursive hand. The two styles developed into two main varieties: (1) the Venetian minuscule, nowadays known as italic, traditionally (though wrongly) considered to be an imitation of Petrarch's handwriting; and (2) the Roman type, preferred in northern Italy, chiefly in Venice, where it was used in the printing presses at the end of the 15th and the beginning of the 16th centuries; from Italy it spread to Holland, England (about 1518), Germany, France, and Spain. The classical Roman character was adopted for the majuscules. This majuscule writing, along with the Roman-type minuscule and the italic, spread all over the world. In England they were adopted from Italy in the 16th century.

The survival of the black letter (Gothic) in Germany is attributed to the fact that it was the current style at the time of the invention of printing in Germany and was thus employed by Gutenberg. In Italy the *littera antiqua* was used by the German printers Konrad Sweynheym and Arnold Pannartz, as well as by Nicolas Jenson, the great Venetian printer who perfected the Roman type.

The modern national alphabets of the western European nations are, strictly speaking, adaptations of the Latin alphabet to Germanic (English, German, Swedish, Dutch, Danish, etc.), Romance (Italian, French, Spanish, Portuguese, etc.), Slavic (Polish, Czech, Slovak, etc.), Baltic (Lithuanian, Latvian), Finno-Ugric (Finnish, Hungarian, etc.), and other languages. The adaptation of a script to a language is not easy, especially when the language contains sounds that do not occur in the speech from which the script has been borrowed. There arises, therefore, the difficulty of representing the new sounds. This difficulty was met quite differently in various alphabets. For instance, the sound *shch* as in English "Ashchurch," which in Russian is represented by one sign (щ), is represented in

Czech by two signs (*šč*), in Polish by four (*szcz*), in English likewise by four, though different ones, and in German by as many as seven (*schtsch*). Thus, in these instances, combinations of two or more letters were introduced to represent the new sounds.

In other cases, new signs were invented; *e.g.,* in the early Greek alphabet and in the Anglo-Saxon adoption of the Latin alphabet. In more recent times the most common way of representing sounds that cannot be represented by letters of the borrowed alphabet has been to add diacritical marks, either above or under the letters, to their right or left, or inside. To this group belong the German vowels *ü, ä, ö;* the Portuguese and French cedilla in *ç;* the tilde on Spanish *ñ* and Portuguese *ã* and *õ;* the Italian *à, é, è, ì, ù,* etc.; the great number of marks in the Latin-Slavic alphabets (Polish, Czech, Croatian, etc.)—*ą, ę, č, ć, š, ś, ž, ż, ź,* and so on. The Latin-Turkish alphabet, introduced in 1928, became general throughout Turkey in 1930. It contains 29 letters, of which two vowels (*ö* and *ü*) and three consonants (*ç, ğ,* and *ş*) are distinguished by diacritical marks; in one instance there is a distinction in reverse— the dot from *i* is eliminated (*ı*) to represent a new sound.

(D.D./D.R.O.)

CHINESE WRITING

Chinese writing and Semitic writing constitute the two great writing systems of the world. Just as the Semitic writing system was fundamental to the evolution of modern writing systems in the West, Chinese script was fundamental to the writing systems in the East. Chinese writing, at least until relatively recently, was more widely in use than alphabetic writing systems, and until the 18th century more than half of the world's books had been written in Chinese, including works of speculative thought, historical writings of a kind, and novels, along with writings on government and law.

When China was united in the 3rd century BC, the first emperor, Shih huang-ti, ordered that the writing system be standardized throughout the empire. This common writing system bound the Chinese people together, forming a medium of communication that could be read by groups who spoke very different, often mutually incomprehensible dialects of the language. Chinese writing is the only form of writing that has been in continuous use from the time of the invention of writing down to the present time.

Chinese script is logographic. Characters or graphs represent not units of sound as in phonographic writing systems but rather units of meaning, morphemes. Chinese, like any other language, has thousands of morphemes, and, as one character is used for each morpheme, the writing system has thousands of characters. Two morphemes that sound the same would, in English, have at least some similarity of spelling; in Chinese they are represented by completely different characters. The Chinese words for "parboil" and for "leap" are pronounced identically. Yet there is no similarity in the way they are written.

The fact that the Chinese script is logographic and that its characters or graphs have a pictorial property has led some writers to conclude that it is less abstract than sound-based writing systems. However, recent scholars point out that all writing systems began with pictorial signs that lost their pictorial properties to the requirement of ease of writing; it is easier to draw an arbitrary sign than a realistic picture. And it is now recognized that a logographic script is a relatively optimal solution to the problem of representing the Chinese language.

The Chinese language has clearly distinguished syllables that are easily recognized in speech and hence easily represented by a sign. These syllables correspond to morphemes; each morpheme is one syllable long. In English one morpheme is often expressed by two syllables (*e.g.,* "balloon"), and two morphemes may be contained in one syllable (*e.g.,* "boys"). In Chinese, with a general correspondence between morpheme and syllable, each morpheme is easily represented by a sign for the corresponding syllable. Moreover, one morpheme in Chinese is more or less equivalent to a word. Unlike English, in which morphemes combine to make new words (*e.g., make* + past = *made*), Chinese is an isolating language, in which elements of meaning

are strung together as a series of isolated morphemes. Similarly, the pronunciation of a syllable is relatively uninfluenced by adjacent syllables, which, therefore, remain relatively invariant. It is these invariant units of sound and meaning that are represented by distinctive logographs.

The earliest characters of the Chinese script were "motivated"; that is, they resembled the things they represented (see above *History of writing systems*). With the adoption of the brush as the tool and of ink on paper as the medium for writing, graphs became essentially arbitrary, involving simple lines and shapes. The basic stock of characters are simple graphs, some of which represent the names for objects or parts of objects, such as river, fish, man, and woman, and others of which stand for more abstract terms, such as yield, love, quarrel, prince, and the like. There are approximately 1,000 of these simple characters or graphs.

These basic characters serve two other roles. First, they may double as loan words. Thus, the character representing the word "prince" doubles for "thin-sliced," "law," "beating the breast," "avoid," and others that were difficult to depict directly. The principle for borrowing the character was that the new word be pronounced in the same or a similar way as the word represented by the character. This acrophonic principle played a similar role in the development of hieroglyphic and cuneiform writing. Indeed, it has been suggested that if this principle had been applied consistently, the Chinese would have ended up with a syllabic rather than a logographic system. However, the writing system would then have been extremely ambiguous, with one character representing a dozen or more unrelated words as a consequence of the extreme homophony of the Chinese language. The logographic principle eliminates that ambiguity by providing one character for one meaning.

The second use of the basic characters was in combination with other characters to make up complex characters. Complex characters consist of one graph representing the pronunciation of the character—that is, a graph standing for a set of similar sounding words based on the acrophonic principle combined with a second graph indicating the semantic category of the word. One part represents the sound of the syllable, the other the semantic category of the morpheme; *e.g.,* the character for "foundation" is composed of the character for "winnowing basket," a word that sounds, in Chinese, similar to the word "foundation," together with the character for "earth," a word that is semantically related to the word "foundation."

其 "winnowing basket," combined with 土 "earth," gives 基 "foundation"

The process of combining simple graphs to make complex ones is enormously prolific and had been used to generate thousands of unique characters capable of representing the morphemes of the language. With some 40,000 graphs, the system comes close to the ideal of a fully explicit writing system that represents each distinctive unit of meaning with a distinctive unit of writing. But, of course, such a large number of graphs imposes a major obstacle to learning to read and write. The problem is made more complex by the fact that neither the sound property nor the semantic property of the characters is of much help in the recognition of a character. Because of changes in pronunciation of the language, the complex signs no longer reflect the sound pattern that they originally grew out of. Similarly, the semantic relations represented by the graph are no longer so clear. Consequently, as the relations between the characters and what they represent are largely unknown to readers and writers of the language, the graphs are seen as groups of lines and angles that make up repeated visual units, just as readers of English recognize whole words without analyzing them into their constituent letters. A literate Chinese person knows perhaps 4,000 of the most important characters.   (D.R.O.)

Adjuncts to writing

PUNCTUATION

Punctuation is the use of spacing, conventional signs, and certain typographical devices as aids to the understanding and correct reading, both silently and aloud, of handwritten and printed texts. The word is derived from the Latin *punctus,* "point." From the 15th century to the early 18th the subject was known in English as pointing; and the term punctuation, first recorded in the middle of the 16th century, was reserved for the insertion of vowel points (marks placed near consonants to indicate preceding or following vowels) in Hebrew texts. The two words exchanged meanings between 1650 and 1750.

Since the late 16th century the theory and practice of punctuation have varied between two main schools of thought: the elocutionary school, following late medieval practice, treated points or stops as indications of the pauses of various lengths that might be observed by a reader, particularly when he was reading aloud to an audience; the syntactical school, which had won the argument by the end of the 17th century, saw them as something less arbitrary, namely, as guides to the grammatical construction of sentences. Pauses in speech and breaks in syntax tend in any case to coincide; and although English-speaking writers are now agreed that the main purpose of punctuation is to clarify the grammar of a text, they also require it to take account of the speed and rhythm of actual speech.

Syntactical punctuation is, by definition, bad when it obscures rather than clarifies the construction of sentences. Good punctuation, however, may be of many kinds: to take two extreme examples, Henry James would be unintelligible without his numerous commas, but Ernest Hemingway seldom needs any stop but the period. In poetry, in which the elocutionary aspect of punctuation is still important, and to a lesser degree in fiction, especially when the style is close to actual speech, punctuation is much at the author's discretion. In nonfictional writing there is less room for experiment. Stimulating variant models for general use might be the light punctuation of George Bernard Shaw's prefaces to his plays and the heavier punctuation of T.S. Eliot's literary and political essays.

Punctuation in Greek and Latin to 1600. The punctuation now used with English and other western European languages is derived ultimately from the punctuation used with Greek and Latin during the classical period. Much work remains to be done on the history of the subject, but the outlines are clear enough. Greek inscriptions were normally written continuously, with no divisions between words or sentences; but, in a few inscriptions earlier than the 5th century BC, phrases were sometimes separated by a vertical row of two or three points. In the oldest Greek literary texts, written on papyrus during the 4th century BC, a horizontal line called the *paragraphos* was placed under the beginning of a line in which a new topic was introduced. This is the only form of punctuation mentioned by Aristotle. Aristophanes of Byzantium, who became librarian of the Museum at Alexandria about 200 BC, is usually credited with the invention of the critical signs, marks of quantity, accents, breathings, and so on, still employed in Greek texts, and with the beginnings of the Greek system of punctuation. Rhetorical theory divided discourse into sections of different lengths. Aristophanes marked the end of the short section (called a *comma*) by a point after the middle of its last letter, that of the longer section (*colon*) by a point after the bottom of the letter, and that of the longest section (*periodos*) by a point after the top of the letter. Since books were still being written in tall majuscule letters, like those used in inscriptions and like modern capital letters, the three positions were easily distinguishable. Aristophanes' system was seldom actually used, except in a degenerated version involving only two points. In the 8th or 9th century it was supplemented by the Greek form of question mark (;). The modern system of punctuating Greek texts was established by the Italian and French printers of the Renaissance, whose practice was incorporated in the Greek types cut by Claude Garamond for Francis I of France between 1541 and 1550. The colon is not used in Greek, and the semicolon is represented by a high point. Quotation marks and the exclamation mark were added more recently.

In almost all Roman inscriptions points were used to separate words. In the oldest Latin documents and books, dating from the end of the 1st century BC to the beginning

Ancient Greek practices

Roman practice

of the 2nd century AD, words were divided by points, and a change of topic was sometimes indicated by paragraphing: the first letter or two of the new paragraph projected into the margin, instead of being indented as has been done since the 17th century. Roman scholars, including the 4th-century grammarian Donatus and the 6th-century patron of monastic learning Cassiodorus, recommended the three-point system of Aristophanes, which was perfectly workable with the majuscule Latin scripts then in use. In practice, however, Latin books in their period were written continuously—the point between words had been abandoned. The ends of sentences were marked, if at all, by only a gap (which might be followed by an enlarged letter) or by an occasional point. The only books that were well punctuated at that time were copies of the Vulgate Bible, for which its translator, St. Jerome (died 419/420), devised punctuation *per cola et commata* ("by phrases"), a rhetorical system, based on manuscripts of Demosthenes and Cicero, which was especially designed to assist reading aloud. Each phrase began with a letter projecting into the margin and was in fact treated as a minute paragraph, before which the reader was expected to take a new breath.

During the 7th and 8th centuries, which saw the transition from majuscule to minuscule handwriting (minuscule scripts were usually smaller than majuscule and had projections above and below the body of the letters, as in modern lowercase letters), scribes to whom the Latin language was no longer as well known as it had been—especially Irish, Anglo-Saxon, and German scribes, to whom it was a foreign language—began to separate words. It was only in the 13th century that monosyllables, especially prepositions, were finally detached from the word following them. The introduction of spaces between words was critical to the development of silent reading, a practice that began only about the 10th century. To mark sentences, a space at the end became the rule; and an enlarged letter, often a majuscule, generally stood at the beginning of sentences and paragraphs alike. The use of points was somewhat confused by St. Isidore of Seville (died 636), whose encyclopaedia recommended an aberrant version of the three-point system; but a point, high or low, was still used within or after sentences. The ends of sentences were often marked by a group of two or three marks, one of which might be a comma and not a simple point.

St. Jerome's concern for the punctuation of sacred texts was shared by Charlemagne, king of the Franks and Holy Roman emperor, and his Anglo-Saxon adviser Alcuin, who directed the palace school at Aachen from 782 to 796. An important element in the educational revival over which they presided was the improvement of spelling and punctuation in biblical and liturgical manuscripts. It is in the earliest specimens of the new Carolingian minuscule script, written at Corbie and Aachen about 780–800, that the first evidence for a new system of punctuation appears. It soon spread, with the script itself, throughout Europe, reaching its perfection in the 12th century. Single interior stops in the form of points or commas and final groups of stops continued in use; but they were joined by the mark later known as *punctus elevatus* (ᛏ) and by the question mark (*punctus interrogativus*), of much the same shape as the modern one but inclined to the right. The source of these two new marks was apparently the system of musical notation, called neumes, which is known to have been used for Gregorian chant from at least the beginning of the 9th century. *Punctus elevatus* and *punctus interrogativus* indicated not only a pause and a syntactical break but also an appropriate inflection of the voice. By the 12th century another mark, *punctus circumflexus* (ᛦ), had been added to *elevatus* to indicate a rising inflection at the end of a subordinate clause, especially when the grammatical sense of the sentence was still not complete. Liturgical manuscripts in particular, between the 10th and the 13th centuries, made full use of this inflectional system: it is the origin of the "colon" still used to divide verses of the Psalms in breviaries and prayer books. In the later Middle Ages it was especially the Cistercian, Dominican, and Carthusian orders and the members of religious communities such as the Brethren of the Common Life who troubled to preserve a mode

of punctuation admirably adapted to the constant reading aloud, in church and refectory, that characterized the religious life. The hyphen, to mark words divided at the ends of lines, appeared late in the 10th century; single at first, it was often doubled in the period between the 14th and 18th centuries.

Most late medieval punctuation was haphazard by comparison with 12th-century work—notably in the university textbooks produced at Paris, Bologna, and Oxford in the 13th and 14th centuries. In them, as elsewhere, a form of paragraph mark representing *c* for *capitulum* ("chapter") is freely used at the beginning of sentences. Within the same period the plain point and *punctus elevatus* are joined by the virgule (/) as an alternative form of light stop. Vernacular literature followed the less formal types of Latin literature; and the printers, as usual, followed the scribes. The first printed texts of the Bible and the liturgy are, as a rule, carefully punctuated on the inflectional principle. The profusion of points and virgules in the English books of the printer William Caxton pays remarkably little attention to syntax. Parentheses appeared about 1500. During the 15th century some English legal documents were already being written without punctuation; and British and American lawyers still use extremely light punctuation in the hope of avoiding possible ambiguities.

The beginnings of postmedieval punctuation can be traced to the excellent manuscripts of classical and contemporary Latin texts copied in the new humanistic scripts by Italian scribes of the 15th century. To about 1450, the point and the *punctus elevatus* seem to have been preferred for minor pauses; after that date they are often replaced by the virgule and what is now called the colon (:). The virgule, originally placed high, sank to the baseline and developed a curve—it turned, in fact, into a modern comma. The Venetian editor and printer Aldus Manutius (Aldo Manuzio; died 1515) made improvements in the humanistic system, and in 1566 his grandson of the same name expounded a similar system in his *Orthographiae ratio* ("System of Orthography"); it included, under different names, the modern comma, semicolon, colon, and full point, or period. Most importantly, the younger Aldo stated plainly for the first time the view that clarification of syntax is the main object of punctuation. By the end of the 17th century the various marks had received their modern names, and the exclamation mark, quotation marks, and the dash had been added to the system.

Punctuation in English since 1600. By the end of the 16th century writers of English were using most of the marks described by the younger Aldo in 1566; but their purpose was elocutionary, not syntactical. When George Puttenham, in his treatise *The Arte of English Poesie* (1589), and Simon Daines, in *Orthoepia Anglicana* (1640), specified a pause of one unit for a comma, of two units for a semicolon, and of three for a colon, they were no doubt trying to bring some sort of order into a basically confused and unsatisfactory situation. The punctuation of Elizabethan drama, of the devotional prose of John Donne or of Richard Hooker, and indeed of Bunyan's *Pilgrim's Progress* (1678) was almost wholly elocutionary; and it lacked the inflectional element that had been the making of 12th-century punctuation. It was Ben Jonson, in his *English Grammar,* a work composed about 1617 and published posthumously in 1640, who first recommended syntactical punctuation in England. An early example is the 1625 edition of Francis Bacon's *Essayes;* and from the Restoration onward syntactical punctuation was in general use. Influential treatises on syntactical punctuation were published by Robert Monteith in 1704 and Joseph Robertson in 1795. Excessive punctuation was common in the 18th century: at its worst it used commas with every subordinate clause and separable phrase. Vestiges of this attitude are found in a handbook published in London as late as 1880. It was the lexicographers Henry Watson Fowler and Francis George Fowler, in *The King's English,* published in 1906, who established the current British practice of light punctuation. Punctuation in the United States has followed much the same path as in Britain, but the rules laid down by American authorities have in general been more rigid than the British rules.

The system of punctuation now used by writers of English has been complete since the 17th century. Three of its most important components are the space left blank between words; the indentation of the first line of a new paragraph; and the uppercase, or capital, letter written at the beginning of a sentence and at the beginning of a proper name or a title. The marks of punctuation, also known as points or stops, and the chief parts that they play in the system are as follows.

The end of a grammatically complete sentence is marked by a full point, full stop, or period. The period may also be used to mark abbreviations. The colon (:), which was once used like a full point and was followed by an uppercase letter, now serves mainly to indicate the beginning of a list, summary, or quotation. The semicolon (;) ranks halfway between a comma and a full point. It may be substituted for a period between two grammatically complete sentences that are closely connected in sense; in a long or complicated sentence, it may precede a coordinate conjunction (such as "or," "and," or "but"). A comma (,) is the "lightest" of the four basic stops. As the most usual means of indicating the syntactical turning points in a sentence, it is exposed to abuse. It may be used to separate the elements of a series, before a relative clause that does not limit or define its antecedent, in pairs to set off or isolate words or phrases, or in combination with coordinating conjunctions.

Other punctuation marks used in modern English include parentheses, which serve, like a pair of commas, to isolate a word or phrase; question, exclamation, and quotation marks; the hyphen; and the apostrophe.

Punctuation in French, Spanish, German, and Russian. Since the modern punctuation of all the western European languages stems from the practice of the great Italian and French printers of the 15th and 16th centuries, national differences are not considerable. In French, guillemets (<<>>) or dashes are used to mark quotations. In Spanish, since the middle of the 18th century, an inverted mark of interrogation or exclamation has stood at the beginning of sentences as well as the normal mark at the end; and quotations may be marked either as in French or as in English. German punctuation, which is still based on rules propounded in 1781, is more rigorously syntactical than the rest: all relative clauses and all clauses beginning with *dass* ("that") must be preceded by a comma. Quotations are marked either by pairs of commas („") or by reversed guillemets (>><<). Letter spacing, as well as italic type, is used for emphasis. Early Russian punctuation was based on Greek practice, since the Cyrillic alphabet is derived from the Greek; and by the 17th century several quite elaborate systems had evolved in different areas. Since the 18th century Russia has used a form of western European punctuation that has much in common with German practice: notably an even wider obligatory use of commas with subordinate and indeed coordinate clauses, and letter spacing (as well as italics) for emphasis. German quotation marks, French guillemets, and dashes may be used for direct speech.

Punctuation in Oriental and African languages. In Hebrew manuscripts written since the 9th century the main use of points is to indicate the vowel sounds, the alphabet being consonantal only. In biblical texts points and commas are used to mark the middle and end of verses; and in the commentaries points mark the end of sentences. Since the late 18th century, when Jews in Germany began to compose secular texts in Hebrew, the punctuation of such texts has been based on German practice. Early Arabic manuscripts had no punctuation, since the structure of the language ensured that the main and subordinate clauses were readily distinguishable without it. After Arabic began to be printed, European punctuation marks were gradually adopted. The first such mark was the reversed comma; it is now the most common and indicates a suitable point at which to pause and draw breath.

In Sanskrit, prose texts use one vertical stroke to mark the end of the sentence, and verse texts use one vertical stroke for the end of a line, two for the end of a couplet. In Bengali, Gujarati, Hindi, and Marathi, the vertical stroke is used as in Sanskrit, in conjunction with other marks

borrowed from English. The diacritical signs and elements of punctuation found in Tamil were introduced early in the 18th century by a Jesuit missionary.

Before the modern period, the grammatical structure of written Chinese was such that no punctuation was required; but in the 19th century editors of texts began to add hollow circles, intended either to mark the ends of phrases or to emphasize particular passages. Since 1912 some of the European punctuation marks have been adopted, notably the marks of interrogation and exclamation and the comma (the hollow circle serves as full point). Direct speech is indicated either by double inverted commas or by an L-shaped mark placed at a corner of the first and last characters. Characters are capitalized by the addition of a straight or wavy line underneath or at the side, according to whether the text is written horizontally or vertically.

In Japan a complicated system of *kaeriten* and *kunten* marks was used from the 8th century onward to clarify the meaning and grammatical construction of texts in Chinese. As a result of contact with Europeans in the 15th and 16th centuries, a hollow point (O) and a reversed virgule (·) were used during the Edo period (1603–1868) as equivalents of the European full point and comma. Since 1868 they have been joined by the solid point (to separate items in a list), by the dash used as in English, and, finally, by the European marks of exclamation and interrogation.

The history of punctuation in Africa is part of the history of the scripts used in different parts of the continent: the Coptic script, based on the Greek alphabet with some additions from demotic writing, for the ancient language of Egypt; a derivative of South Semitic script, known as Ethiopic, for the languages of Ethiopia; Arabic script for speakers of Arabic, Berber, and Swahili; Latin—*i.e.*, European—script for the languages first recorded during and since the 19th century.   (T.J.Br.)

SHORTHAND

Shorthand is a method of writing rapidly by substituting characters, abbreviations, or symbols for letters, words, or phrases. Other names for shorthand are stenography (close, little, or narrow writing), tachygraphy (swift writing), and brachygraphy (short writing). Because shorthand can be written rapidly, the shorthand writer is able to record the proceedings of legislative bodies, the testimony of law courts, or dictation in business correspondence. In addition, shorthand has been used through the centuries as a cultural tool: George Bernard Shaw wrote his plays in shorthand; Samuel Pepys recorded his diary in shorthand; Cicero's orations, Martin Luther's sermons, and Shakespeare's plays were all preserved by means of shorthand.

History and development of shorthand. Through the centuries shorthand has been written in systems based on orthography (normal spelling), on phonetics (the sounds of words), and on arbitrary symbols, such as a small circle within a larger circle to represent the phrase, "around the world." Most historians date the beginnings of shorthand with the Greek historian Xenophon, who used an ancient Greek system to write the memoirs of Socrates. It was in the Roman Empire, however, that shorthand first became generally used. Marcus Tullius Tiro, a learned freedman who was a member of Cicero's household, invented the *notae Tironianae* ("Tironian notes"), the first Latin shorthand system. Devised in 63 BC, it lasted over a thousand years. Tiro also compiled a shorthand dictionary. Among the early accomplished shorthand writers were the emperor Titus, Julius Caesar, and a number of bishops. With the beginning of the Middle Ages in Europe, however, shorthand became associated with witchcraft and magic, and disappeared.

While he was archbishop of Canterbury, Thomas Becket (*c.* 1118–70) encouraged research into Tiro's shorthand. By the 15th century, with the discovery in a Benedictine monastery of a lexicon of Ciceronian notes and a Psalter written in Tironian shorthand, a renewed interest in the practice was aroused. Somewhat influenced by Tiro's system, Timothy Bright designed an English system in 1588 that consisted of straight lines, circles, and half circles.

Characteristics of German punctuation

"Tironian notes"

(Tiro's method was cursive, based on longhand script.) Bright's system was called *Characterie: an Arte of Shorte, Swifte, and Secrete Writing by Character.*

The 17th century produced four important inventors of shorthand systems: John Willis, who is considered to be the father of modern shorthand; Thomas Shelton, whose system was used by Samuel Pepys to write his famous diary; Jeremiah Rich, who popularized the art by publishing not only his system but also the Psalms and the New Testament in his method of shorthand; and William Mason, whose method was used to record sermons and to translate the Bible in the years following the Reformation. Mason's system was later adapted and became the official system of the British Parliament.

Several other systems were invented in the next decades, but most of them were short-lived. One of the most successful was that of the British stenographer Samuel Taylor, who invented a system in 1786 that was based on that of one of his predecessors. Taylor's method was adapted into French, Spanish, Portuguese, Italian, Swedish, German, Dutch, Hungarian, and other languages.

The Industrial Revolution brought a demand for stenographers in business. Because the geometric systems then in use required a high level of education and long training, a need existed for a method that would be easier to learn. The German Franz Xaver Gabelsberger (1789–1849) turned away from geometric methods and developed a simple cursive system. Gabelsberger's system, which he called "Speech-sign art," was based on Latin longhand characters and had a neatness and beauty of outline that is unsurpassed. It enjoyed a spontaneous success and spread to Switzerland, Austria, Scandinavia, Finland, and Russia. The system's simplicity made it an easy matter to translate it into other languages, and in 1928 it became the Italian national system.

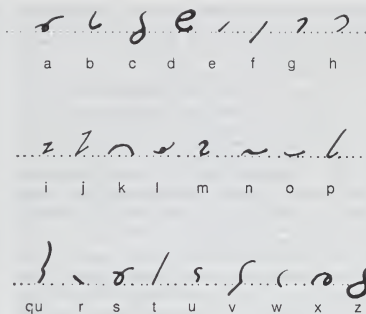
Pitman's system

Modern symbol systems. Sir Isaac Pitman (1813–97), an educator who advocated spelling reform, was knighted by Queen Victoria for his contributions to shorthand. Pitman had learned Taylor's method of shorthand but saw its weakness and designed his own system to incorporate writing by sound, the same principle he advocated in phonetic longhand spelling. He published his system in 1837, calling it *Stenographic Sound-Hand.* It consisted of 25 single consonants, 24 double consonants, and 16 vowel sounds. Similar, related sounds were represented by similar signs, shading was used to eliminate strokes, the shortest signs were used to represent the shortest sounds, and single strokes were used to represent single consonants. At first, the principle of positioning to express omitted vowels—*i.e.,* writing the word above, on, or below the line of writing—was reserved until later lessons, after the theory had been presented. Later, positioning was introduced with the first lesson.

In 1852 Isaac Pitman's brother, Benn Pitman, brought the system to America, where, with several slight modifications, it became the method most extensively used in the United States and Canada. An investigation in 1889 stated that 97 percent of the shorthand writers in America used the Isaac Pitman system or one of its modifications. Pitman shorthand has been adapted to Afrikaans, Arabic, Armenian, Dutch, French, Gaelic, German, Hebrew, Hindi, Italian, Japanese, Persian, Spanish, and other languages.

The Irish-born John Robert Gregg (1867–1948) taught himself at the age of 10 an adaptation of Taylor's shorthand. He then studied Pitman by himself but disliked its angles, shading, and positioning. Later, while in his early teens, he read a history of shorthand by Thomas Anderson, a member of the Shorthand Society of London. Anderson listed the essentials of a good shorthand system, stating that no method then in use possessed them: independent characters for the vowels and consonants, all characters written with the same thickness, all characters written on a single line of writing, and few and consistent abbreviation principles.

Gregg's light-line phonography

Gregg was 18 when he invented his own system and 21 when he published it in the form of a pamphlet, *Light-Line Phonography* (1888). The Gregg system was predominantly a curve-motion shorthand with circles, hooks, and loops. Based on the ellipse or oval and on the slope


Alphabet of Gabelsberger shorthand, 1834.
From Hans Glatte, *Shorthand Systems of the World*

of longhand, its motion was curvilinear. Obtuse angles were eliminated by natural blending of lines, vowels were joined, shading was eliminated, and writing was lineal, or in one position.

In 1893 Gregg took his system to the United States, and Light-Line Phonography became Gregg Shorthand. The inventor found that, except for the eastern coastal cities, shorthand was virtually unknown. At that time high schools began teaching shorthand, and Gregg traveled through the Midwest, the West, and the South, selling his system and demonstrating his teaching methods with great success. The Gregg system supplanted Pitman's as the predominant system taught in the United States. It also spread to Canada and to the British Isles. Gregg shorthand has been published in English, French, Spanish, Portuguese, Hebrew, Russian, Italian, Tagalog, Japanese, Thai, Chinese, Scottish Gaelic, Esperanto, Sinhalese, and Polish.

An early German system of importance was the Stolze-Schrey method. Wilhelm Stolze invented his system at about the same time as Gabelsberger and along similar lines. In 1885 Ferdinand Schrey, a Berlin merchant, attempted to simplify the Gabelsberger system. Sometime later the Stolze and Schrey methods were merged and became the leading system in Germany and Switzerland. Stolze-Schrey shorthand was also adapted to other languages, including Danish, Dutch, English, French, Italian, Norwegian, Polish, Russian, and Spanish.

In 1924, after two decades of development, a new system based on the Gabelsberger and Stolze-Schrey methods was completed. As revised in 1936 and 1968, the Deutsche Einheitskurzschrift is the principal system now used in Germany and Austria.
Pitman
Gregg
Speedwriting

Modern systems of shorthand recording the same sentence: "Since the dawn of history man has strived to communicate with his fellows and to record experiences that would otherwise be forgotten."

Modern abbreviated longhand systems. The system of Speedwriting shorthand was created around 1924 by Emma Dearborn, an instructor at Columbia University. Her method was designed to be taken down on the typewriter; but in 1942 it was changed to be written by hand with pen or pencil. Speedwriting shorthand uses the letters of the alphabet and the known punctuation marks to represent sounds. For example, the sound of *ch* is written with a capital *C;* the word *each* is thus written *eC.* More than 20,000 words in the Speedwriting dictation can be written with a total of 60 rules and a list of approximately 100 brief forms and standard abbreviations. Speedwriting shorthand is taught in several languages—including English, Spanish, Italian, Portuguese, German, Flemish, and Afrikaans—in many countries.

Forkner Alphabet shorthand was first published in 1952 in the United States. The author, Hamden Forkner, spent 10 years in research before publishing the first edition of the new system, which uses a combination of conventional letters and a few symbols for the hard-to-write letters and sounds. For example, *H* is expressed by a short dash above the line. This same short dash through the letter *C* gives the *ch* sound, through the longhand *S* it gives *sh,* and across the *T* it designates *th.* Abbreviations are used for a number of common words.

Another American method, Hy-Speed Longhand, was first published under that title in 1932. Based on Andrew J. Graham's *Brief Longhand,* published in 1857, its principles include the omission of silent letters and most vowels, the substitution of letters, numbers, or signs, and the combination of certain letters.

Stenoscript ABC Shorthand is a phonetic system using only longhand and common punctuation marks. It originated in London in 1607 and was revised by Manuel Claude Avancena, who published a modern edition in 1950. Stenoscript has 24 brief forms that must be memorized; *e.g., ak* stands for *acknowledge, ac* for *accompany, bz* for *business,* and *gvt* for *government.*

Stenospeed originated in 1950 in the United States; the first publication was called Stenospeed High Speed Longhand, but in 1951 the system was revised under the name of Stenospeed ABC Shorthand. It is used by many schools as a standard text.

Other alphabetic or partially alphabetic systems have also been devised. Among these is Teeline, a system used extensively in Great Britain.

Machine shorthand. A method of recording speech by using machines became commercially feasible around 1906, when the Stenotype machine was invented by Ward Stone Ireland, an American stenographer and court reporter. At present, the Stenograph and Stenotype machines are used in offices to some extent, but they are principally employed for conference and court reporting. Both machines have keyboards of 22 keys. Because the operator uses all fingers and both thumbs, any number of keys can be struck simultaneously. The machines print roman letters on a strip of paper that folds automatically into the back of the machine. The operator controls the keys by touch and is thus able to watch the speaker. The fingers of the left hand control the keys that print consonants occurring before vowels. These keys print on the left side of the tape. The thumbs control the vowels, which are printed in the centre of the tape, and the fingers of the right hand control the consonants that follow the vowels, which are printed on the right side of the tape. There are not separate keys for each letter of the English alphabet; thus, those letters for which there are no keys are represented by combinations of other letters. Abbreviations are used for some of the most frequent words, giving the operator the ability to write two or three words in one stroke. (A.R.R./Ed.)

Handwriting and calligraphy

EARLY SEMITIC WRITING

During the 2nd millennium BC, various Semitic peoples at the eastern end of the Mediterranean were experimenting with alphabetic writing. Between 1500 and 1000 BC, alphabetic signs found in scattered sites showed a correspondence of form and provided material for sound translations. Bodies of writing from this period are fragmented: a few signs scratched on sherds or cut in stone. Few of these are celebrated in terms of aesthetic value.

One interesting set of Semitic inscriptions was discovered in 1905 at an ancient mining site on the Sinai Peninsula. A sphinx from that discovery yields the *taw, nun, taw,* or *t, n, t,* meaning "gift." It is evident that the *nun,* or *n,* sign is a rendering of a serpent. Most of the early Semitic alphabetic signs were similarly derived from word signs of more ancient vintage.

The several Semitic peoples in the Middle East area spoke languages that were closely related, and this enabled them to use the same set of alphabetic signs. After some experimentation the alphabet was reduced to 22 signs for consonants. There were no vowel signs. The tribes of Canaan (Hebrews, Phoenicians, and Aramaeans) were important in the development of alphabetic writing, and all seemed to be employing the alphabet by 1000 BC.

The Phoenicians, living along a 20-mile (30-kilometre) strip on the Mediterranean, made the great sea their second home, giving the alphabet to Greeks in the mutual trading area and leaving inscriptions in many sites. One of the finest Phoenician inscriptions exists on a bronze cup from Cyprus called the Baal of Lebanon (Louvre, Paris) dating from *c.* 800 BC. The so-called Moabite Stone (Louvre), *c.* 850 BC, has an inscription that is also a famous example of early Semitic writing.

Old Hebrew. Old Hebrew existed in inscription form in the early centuries of the 1st millennium BC. The pen-written forms of the Old Hebrew alphabet are best preserved in the 13th-century-AD documents of the Samaritan sects.

The exile suffered by the Israelites (586–538 BC) dealt a heavy blow to the Hebrew language, since, after their return from exile, Aramaic was the dominant language of the area, and Hebrew existed as a second and scholarly language. Aramaic pen-written documents begin to appear in the 5th century BC and are vigorous interpretations of inscription letters. As seen in the Aramaic document (MS. Pell. Aram. XIV) in the Bodleian Library at Oxford, the penman has cut the pen wide at the tip to produce a pronounced thick and thin structure to the line of letters. The penman's hand was rotated counterclockwise more than 45 degrees relative to vertical, so that vertical strokes were thinner than the horizontal ones. Then, too, there is a tendency to hold these strong horizontals on the top line, with trailing descenders finding a typical length, long or short on the basis of ancient habits. The *lamed* form, which has the same derivation as the Western L, resembles the latter and can be picked out in early Aramaic pen hands by its characteristic long ascender.

The traditional square Hebrew, or *merubba',* pen hand was developed in the centuries preceding the Christian Era. This early script may be seen in the famed Dead Sea Scrolls discovered in 1947. These scrolls are associated with a group of dissident Jews who founded a religious commune on the northwestern shore of the Dead Sea about 180 BC. The commune had an extensive library. Pens were the instruments of writing, and, as in earlier Aramaic documents, leather provided the surface. Again the *lamed* form is visually prominent.

There are no Hebrew manuscripts from the first 500 years of the Christian Era. Most of the development in the

Merubba' script

square Hebrew script occurred between AD 1000 and 1500. The earliest script to emerge from the Dead Sea writing was the Early Sefardic (Spharadic), with examples dating between AD 600 and 1200. The Classic Sefardic hand appears between AD 1100 and 1600. The Ashkenazic style of Hebrew writing exhibits French and German Gothic overtones of the so-called black-letter styles (see below) developed to write western European languages in the late Middle Ages. German black letter, with its double-stroked heads and feet, was difficult for the scribe. Hebrew scripts from this period exhibit some of the same complicated pen stroking and change of pen slant within individual characters. Some decorative qualities of medieval French writing are seen in this Hebrew script.

Sefardic and Ashkenazic styles (margin note)

Spread of Aramaic to the Middle East and Asia. Aramaic was the mother of many languages in the Middle East and Asia. Generally, the Canaanite-Phoenician influence went west from Palestine, while Aramaic became an international language spreading east, south, and north from the eastern end of the Mediterranean Sea. Never sponsored by great political power, the Aramaic script and language succeeded through inherent efficiency and because the Aramaeans were vigorous traders and extensive travellers in the millennium preceding the birth of Christ.

One of the important languages to derive from Aramaic was Syriac. It was spoken over large areas to the north and east of Palestine, but the literature emerged from a strong national church of Syria centred in the city of Edessa. The development of Syriac scripts occurred from the 4th to the 7th century AD.

Eastern Christendom was riddled with sects and heretical movements. After 431 the Syriac language and script split into eastern and western branches. The western branch was called Serta and developed into two varieties, Jacobite and Melchite. Vigorous in pen graphics, Serta writing shows that, unlike the early Aramaic and Hebrew scripts, characters are fastened to a bottom horizontal. Modern typefaces used to print Syriac, which has survived as a language, have the same characteristic. Eastern Syriac script

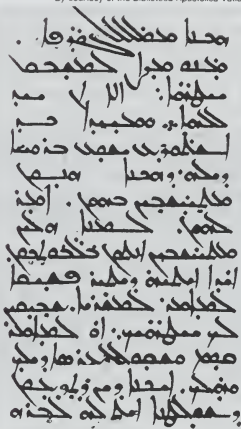
Serta and Nestorian writing (margin note)

was called Nestorian after Nestorius, who led a secession movement from the Orthodox Church of Byzantium that flourished in Persia and spread along trade routes deep into Asia. (D.An./Ed.)

ARABIC CALLIGRAPHY

In the 7th and 8th centuries AD the Arab armies conquered for Islām territories stretching from the shores of the Atlantic to Sind (now in Pakistan). Besides a religion, they brought to the conquered peoples a language both written and spoken. The Arabic language was a principal factor in uniting peoples who differed widely in race, language, and culture. In the early centuries of Islām, Arabic not only was the official language of administration but also was and has remained the language of religion and learning. The Arabic alphabet has been adapted to the Islāmic peoples' vernaculars just as the Latin alphabet has been in the Christian West.

The Arabic script was evolved probably by the 6th century AD from Nabataean, a dialect of Aramaic current in northern Arabia. The earliest surviving examples of Arabic before Islām are inscriptions on stone.

By courtesy of the Biblioteca Apostolica Vaticana


Jacobite script, 1481 (Vatican City, Biblioteca Apostolica Vaticana, 30.b Vat. syr. 18).

Arabic is written from right to left and consists of 17 characters, which, with the addition of dots placed above or below certain of them, provide the 28 letters of the Arabic alphabet. Short vowels are not included in the alphabet, being indicated by signs placed above or below the consonant or long vowel that they follow. Certain characters may be joined to their neighbours, others to the preceding one only, and others to the succeeding one only. When coupled to another, the form of the character undergoes certain changes.

These features, as well as the fact that there are no capital forms of letters, give the Arabic script its particular character. A line of Arabic suggests an urgent progress of the characters from right to left. The nice balance between the vertical shafts above and the open curves below the middle register induces a sense of harmony. The peculiarity that certain letters cannot be joined to their neighbours provides articulation. For writing, the Arabic calligrapher employs a reed pen (*qalam*) with the working point cut on an angle. This feature produces a thick downstroke and a thin upstroke with an infinity of gradation in between. The line traced by a skilled calligrapher is a true marvel of fluidity and sensitive inflection, communicating the very action of the master's hand.

Broadly speaking, there were two distinct scripts in the early centuries of Islām: cursive script and Kūfic script. For everyday purposes a cursive script was employed: typ-

ical examples are to be seen in the Arabic papyri from Egypt. Rapidly executed, the script does not appear to have been subject to formal and rigorous rules, and not all the surviving examples are the work of professional scribes. Kūfic script, however, seems to have been developed for religious and official purposes. The term Kūfic means "the script of Kūfah," an Islāmic city founded in Mesopotamia in AD 638, but the actual connection between the city and the script is not clear. Kūfic is a more or less square and angular script. Professional copyists employed a particular form for reproducing the earliest copies of the Qur'ān that have survived. These are written on parchment and date from the 8th to the 10th century. They are mostly of an oblong as opposed to codex format. The writing is frequently large, especially in the early examples, so that there may be as few as three lines to a single page. The script can hardly be described as stiff and angular; rather, the pace is majestic and measured.

Kūfic went out of general use about the 11th century, although it continued to be used as a decorative element contrasting with those scripts that superseded it. About AD 1000 a new script was established and came to be used for copying the Qur'ān. This is the so-called *naskhī* script, which has remained perhaps the most popular script in the Arab world. It is a cursive script based on certain laws governing the proportions between the letters. The two names associated with its development are Ibn Muqlah and Ibn al-Bawwāb, both of whom lived and worked in Mesopotamia. Of the latter's work a single authentic example survives, a manuscript of the Qur'ān in the Chester Beatty Library, Dublin.

Distinctive scripts were developed in particular regions. In Spain the *maghribī* ("western") script was evolved and became the standard script for Qur'āns in North Africa. Derived ultimately from Kūfic, it is characterized by the exaggerated extension of horizontal elements and of the final open curves below the middle register.

Both Persia and Turkey made important contributions to calligraphy. In these countries the Arabic script was adopted for the vernacular. The Persian scribes invented the *ta'līq* script in the 13th century. The term *ta'līq* means "suspension" and aptly describes the tendency of each word to drop down from its preceding one. At the close of the same century, a famous calligrapher, Mīr 'Alī of

Establishment of *naskhī* script

Development of *ta'līq* and *nasta'līq* in Persia

Tabriz, evolved *nasta'līq,* which, according to its name, is a combination of *naskhī* and *ta'līq.* Like *ta'līq,* this is a fluid and elegant script, and both were popularly used for copying Persian literary works.

A characteristic script developed in Ottoman Turkey was that used in the chancellery and known as *divani.* This script is highly mannered and rather difficult to read. Peculiar to Turkish calligraphy is the *tuğra* (*tughrā*), a kind of royal cipher based on the names and titles of the reigning sultan and worked into a very intricate and beautiful design. A distinctive *tuğra* was created for each sultan and affixed to imperial decrees by a skilled calligrapher, the *neshanı.*

Maghribi script. Qur'ān from northwest Africa or Spain, 13th–14th century. In the British Museum, London.

There has always existed in the Islāmic world a keen appreciation of fine handwriting, and, from the 16th century, it became a practice to assemble in albums specimens of penmanship. Many of these assembled in Turkey, Persia, and India are preserved in museums and libraries. Calligraphy, too, has given rise to quite a considerable literature such as manuals for professional scribes employed in chancelleries.

In its broadest sense, calligraphy also includes the Arabic scripts employed in materials other than parchment, papyrus, and paper. In religious buildings, verses from the Qur'ān were inscribed on the walls for the edification of the faithful, whether carved in stone or stucco or executed in faience tiles. Religious invocations, dedications, and benedictory phrases were also introduced into the decoration of portable objects. Generally speaking, there is a

close relationship between these and the scripts properly used on the conventional writing materials. It was often the practice for a skilled penman to design monumental inscriptions.   (R.H.P.-W./Ed.)

INDIC CALLIGRAPHY

The most important examples of calligraphy to develop from Aramaic writing in its dissemination through southern and Central Asia were the scripts of India, especially of Sanskrit. Indic writing first appeared in the 3rd century BC during the reign of Aśoka (*c.* 265–238 BC). Leader of a great empire, Aśoka turned from military success to embrace the arts and religion. Aśoka's edicts were committed to stone. These inscriptions are stiff and angular in form. Following the Aśoka style of Indic writing, two new calligraphic types appear: Kharoṣṭī and Brāhmī. Kharoṣṭī was used in the northwestern regions of India from the 3rd century BC to the 4th century of the Christian Era, and it was used in Central Asia until the 8th century. It is characterized by a vigorous pen letter, reflecting the influence of Middle East calligraphy.

Copper was a favoured material for Indic inscriptions. In the north of India, birch bark was used as a writing surface as early as the 2nd century AD. Many Indic manuscripts were written on palm leaves, even after the Indian languages were put on paper in the 13th century. Both sides of the leaves were used for writing. Long rectangular strips were gathered on top of one another, holes were drilled through all the leaves, and the book was held together by string. Books of this manufacture were common to Southeast Asia. The palm leaf was an excellent surface for penwriting, making possible the delicate lettering used in many of the scripts of southern Asia.

Visually, Sanskrit is associated most closely with the alphabetic form named Devanāgarī. In a 15th-century penwritten manuscript in the Freer Gallery at Washington, D.C., it can be observed that the pen's nib is cut wide, giving a considerable difference in thick and thin strokes.

Sanskrit pen-written document, 15th century AD (Washington, D.C., Freer Gallery, MS. 23.3).

The alphabetic signs hang down from a strong horizontal top line that may become connected. Through the years the strong horizontal and vertical emphasis of inscription writing has been preserved in the Devanāgarī script, and modern typefaces and teaching manuals stress this stiffness of execution. In informal documents this historical script can have more warmth and grace.   (D.An.)

GREEK HANDWRITING

Origins to the 8th century AD.   The oldest Greek writing, syllabic signs scratched with a stylus on sun-dried clay, is that of the Linear B tablets found in Knossos, Pylos, and Mycenae (1400–1200 BC). Alphabetic writing, in use before the end of the 8th century BC, is first found in a scratched inscription on a jug awarded as a prize in Athens. The consensus is that the Homeric poems were written down not later than this time; certainly from the time of the first known lyric poet of ancient Greece, Archilochus (7th century BC), individuals committed their works to writing. But the vehicles of literary writing have perished. Scratchings on pottery or metal and then texts deliberately cut in bronze or marble or painted on vases are, until *c.* 350 BC, the only immediate evidence for the way the Greeks wrote, and their study is normally treated as the province of epigraphy. A find in 1962 at Dervéni (Dhervénion), in Macedonia, of a carbonized roll of papyrus (Archaeological Museum, Thessaloníki, Greece) offers the oldest example of Greek handwriting and the only one preserved in the Greek peninsula (end of the 4th
Papyrus from Dervéni, Macedonia, 4th century BC (Archaeological Museum, Thessaloníki, Greece).

century BC). From then until the 4th century AD, there are countless texts, especially on papyrus. Found in Egypt and, with a few exceptions, written there, these texts have given a firm foundation for knowledge. From outside Egypt there is a Greek library buried in Herculaneum, AD 79; and papyri and parchments from Owrāmān, Kurdistan, 1st century BC; from Doura-Europus on the Euphrates, 3rd century BC to 3rd century AD; from Nessana, 6th century AD; and from the Dead Sea area (Qumrān, 1st centuries BC and AD; Murabba'at and 'En Gedi, 2nd century AD). A number of original vellum manuscripts have survived from the 4th century AD onward, preserved in libraries such as at the monastery of St. Catherine at Mt. Sinai. These materials of diverse origin suggest that the forms and shape of Greek handwriting were remarkably constant throughout the Greek world, wherever writing was practiced and whatever the material used; within this consistent framework it is occasionally possible to distinguish local variations (as between the contract hands of 1st-century-AD Doura and of Egypt).

The principal vehicles for writing were wax tablets incised with a stylus or a prepared surface of skin, such as leather and vellum, or of papyrus written on with a pen. Other surfaces—*e.g.,* broken pieces of pottery, lead, wood, and even cloth—were also used. To some extent the forms of letters were affected by the resistance of the material to the writing instrument. It is likely that the use as a pen of a hard reed, split at the tip and cut into a nib (which must be constantly sharpened), is an invention of the Greeks. Egyptian scribes used a soft reed, with which ink was brushed on.

Marginal notes:

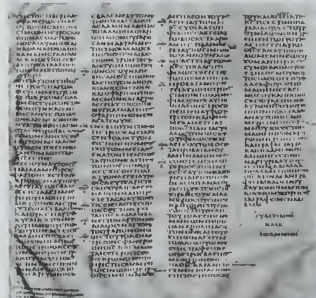
- Writing materials

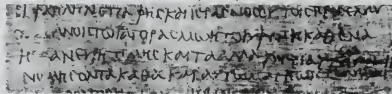
Until about AD 300, ink was normally made of a carbon such as lampblack, mixed with gum and water, which even today retains its black lustre. After that time, because of the increasing popularity of vellum, iron inks (*e.g.*, of oak galls), better suited to vellum, tended to replace carbon. The iron inks have faded with age and often have eaten by chemical action into the vellum. Erasures could be made on wax with the blunt end of the stylus and on papyrus by wiping with a sponge; but, on vellum written in iron ink, erasures could be made only by rubbing with pumice or scraping with a knife. Texts from which a previous writing was deliberately erased to provide writing material are termed palimpsests.

Papyrus was normally sold in rolls (*volumina*) made up of 20 or 50 glued sheets: the horizontal fibres of the papyrus are placed on the inside of the roll, on which side (the recto) each gummed sheet overlaps the next when the roll is held horizontally. Leather, similarly, was for long made into rolls (the Dead Sea Scrolls). Shortly after the beginning of the Christian Era, the custom began of folding a single sheet (or several superposed sheets, a quaternion **Develop-** or quire) down the middle and stitching the quires into a **ment of** binding case to give a book of modern form (codex, origi- **the** nally a set of wax tablets coupled with a thong). Tradition **book** associated this invention with Pergamum.

The decisive impetus to the use of this form came from the early Christians, who deliberately chose the commercial vellum notebook (*membranae*) in which to circulate the Christian Gospels in preference to the traditional Jewish roll. Almost without exception the earliest texts of the New Testament are in codex form, even though written on papyrus, which is less able than vellum to bear repeated bending. In the 2nd century AD, pagan works of literature also appeared in this format. By the 4th century it became the predominant form, and codices with handsome margins, of dazzling white vellum, and of sufficient size to contain the whole Bible (*e.g.*, the Codex Sinaiticus) were being produced.

The fundamental distinction in types of handwriting is that between book hands and documentary hands. The **Book** former, used especially for the copying of literature, aimed **hands** at clarity, regularity, and impersonality and often made an effect of beauty by their deliberate stylization. Usually they were the work of professionals. Outstanding calligraphy is not common among papyrus finds, perhaps because they are mainly provincial work. But the British Museum Bacchylides or the Bodleian Library Homer can stand comparison with any later vellum manuscript from outside Egypt. Book texts are written in separately made capitals (often called uncials, but in Greek paleography, except for the time-hallowed class of biblical uncials, the term is better avoided) in columns of writing, with ample spaces between columns and good margins at head and foot. Punctuation (usually by high dot) is minimal or completely absent; accents are inserted only in difficult poetic texts or as practice by schoolboys; and letters are not grouped into separate words.


Codex Sinaiticus (British Museum, Add. MS. 43725, fol. 260).
Greek book hand. Bodleian Library Homer, passage from the *Iliad*, copied in the 2nd century AD (Oxford, Bodleian Library, MS. Gr. class A.1 (P)).

Documentary hands show a considerable range: stylized **Docu-** official "chancery" hands, the workaday writing of govern- **mentary** ment clerks or of the street scribes who drew up wills or **hands** wrote letters to order, the idiosyncratic or nearly illiterate writing of private individuals. The scribe's aim was to write quickly, lifting his pen very little and consequently often combining several letters in a continuous stroke (a ligature); from the running action of the pen, this writing is often termed cursive. He also made frequent use of abbreviations. When the scribe was skillful in reconciling clarity and speed, such writing may have much character, even beauty; but it often degenerates into a formless, sometimes indecipherable, scrawl.


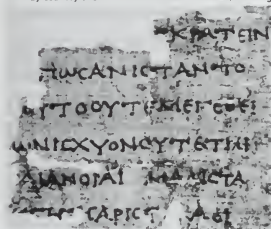
Greek documentary hand. An authorization for the sale of slaves, late 1st century AD (British Museum, P. Oxy. 94).

Both types of hands, in spite of the different styles they assume at different periods, show remarkable uniformity and continuity in the shapes of letters. Behind both lies an unvarying basic alphabetic form taught in the schools. The more skillful a book-hand scribe was, the harder it is to date his work. Documents in the ancient world carried a precise date; books never did. To assign dates to the latter, the paleographer takes account of their content, the archaeological context of their discovery, and technical points of book construction (*e.g.*, quires, rulings) or modes of abbreviation. But he finds of great service: (1) a stylistic comparison with those dated documentary hands that show resemblances to book hands, and (2) those cases where a roll was reused—*i.e.*, has a literary text on its recto **Dated texts** and a dated document on its verso (in which case there is a *terminus ante quem* for the literary text, often estimated at 50 years before the date of the verso) or has a dated document on the recto and a book hand on the verso (which gives a *terminus post quem* for the literary text, not more than 25 years after the document). The number of illustrated manuscripts of this period is small; their quality is varied; and there is no agreement among specialists about the sources from which illustrations were taken.

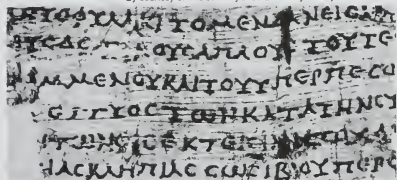
Any historical sketch is bound to be a simplification. At certain epochs several different styles of handwriting existed simultaneously, so that there is no straight line of development. Moreover, owing to the arbitrariness of finds, generalizations are based mainly on provincial work; and, even in that, examples of book hand belonging to the 2nd century BC and the 5th century AD are still relatively rare.

Ptolemaic period. In the roll from Dervéni, Macedonia, dated on archaeological grounds to the 4th century BC, lines and letters are well spaced and the letters carefully made in an epigraphic, or inscription, style, especially the square E, four-barred Σ, and arched Σ; the whole layout gives the effect of an inscription. In the Timotheus roll in Berlin (dated 350–330 BC) or in the curse of Artemisia in Vienna (4th century BC), the writing is cruder, and ω is in transition to what is afterward its invariable written form. Similar features can be seen in the earliest precisely dated document, a marriage contract of 311 BC. It has been argued that a documentary hand of cursive type had not yet been developed and that it was a creation of the

Alexandrian library. Plato, however (*Laws* 810), speaks of Athenian writing whose aim was speed; later on, when a cursive hand had certainly been developed, documentary scribes often used separate capitals.

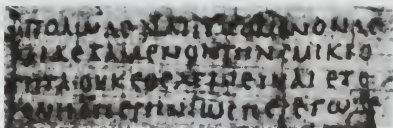
Characteristic of its period is the contrast of size between the long letters (*e.g.,* Μ) and narrow letters (ε C O or θ, O, or O). And characteristic forms are to be seen in the letters ⊤ (with its long crossbar, often with initial stroke); ⊻ (upsilon) with long shallow bowl; Μ or Μ in three or four strokes; ⊼ in three strokes; ⊔ (alpha) raised off the line and its last vertical not finished; small round (·) (with internal dot or tiny stroke); and broad epigraphic ⋏ and Η. These same features, written with more regularity, appear in the contemporary book hand of a fragment of a Thucydides manuscript (Staats- und Universitätsbibliothek,


Thucydides manuscript, 3rd century BC (Hamburg, Staats- und Universitätsbibliothek, P. Hamburg 163).

Hamburg). In documentary cursive hands of this period, letters seem to hang from an upper line: ⊬ (alpha) often turns into a mere wedge, and ⊓ (nu) lifts its second vertical above the line. In the 2nd century BC the contrast between long letters and narrow letters disappears, the writing grows rounder, and letters are often linked by ligatures at the top of their last vertical (*e.g.,* ⊢ Μ Ν). In a loan contract of 99 BC (The John Rylands University Library of Manchester),


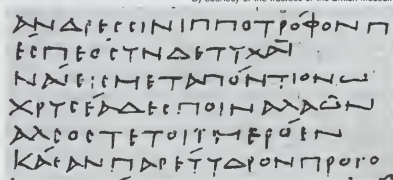
Legal text of a loan contract, 99 BC (The John Rylands University Library of Manchester, Rylands Greek Pap. 586).

in which capitals and cursive are mixed, this irregular roundness is clearly seen. Note the ε with detached crossbar and the exaggerated serifs (Τ Κ Υ ρ) which have been elevated by some paleographers into a criterion of a special style, though in fact they are always apt to occur.

Roman period. Half a century or so passes after 30 BC before a definitely Roman manner is established. In documentary hands the tendency to roundness continues. Documentary cursive may be influenced in various ways (*e.g.,* by Latin forms such as those of *e* and *d,* or by the


Phaedo, by Plato, copied in AD 100 (London, Egypt Exploration Society, P. Oxy. 1809).

exaggeration of verticals practiced by chancery scribes), may lean over in either direction, or may be reduced to tiny proportions. In the 2nd century the cursive hand tends to be round and sprawling, in the 3rd century to become more angular, and in the 4th century to become characterless and to combine letters into ligatures that distort the forms of the letters concerned. The book hand of a manuscript of Plato's *Phaedo* (*c.* AD 100; Egypt Exploration Society, London) shares its informality but regularizes the letter forms. Written on a larger scale and with more formality, this round hand can be very beautiful. In an example found at Hawara (2nd century AD), almost every letter (even ρ, τ, ι) would go into an identical square; only φ and ψ cross it above and below, μ, ω, and π horizontally.

If this writing is made to lean to the right and to revive the 3rd-century-BC distinction between narrow and broad letters, it takes on the aspect of the "severe" style of the Bacchylides roll in the British Museum (2nd century AD). If, however, the scribe makes his verticals or obliques


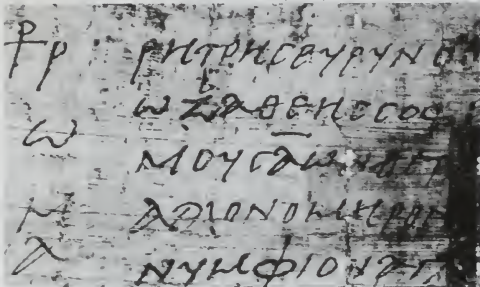
The "severe" style. Bacchylides roll, 2nd century AD (British Museum, P. 733).

thicker and his horizontals thinner, the hand is called biblical uncial, so named because this type is used in the three great early vellum codices of the Bible: Codex Vaticanus and Codex Sinaiticus of the 4th century and Codex Alexandrinus of the 5th century. It is now certain that this style goes back to the 2nd century AD. In the Dioscorides herbal in Vienna, written in AD 512, the writing is rigid and lumbering; the thick strokes are overdone; and blobs of ink terminate the horizontals of, for example, δ, ε, σ, τ. Such heavy decoration is also a feature of the Coptic style, of which there are examples as early as the 2nd century AD. This hand may be thought of as constituting a special case of biblical uncial.

Byzantine period. For the paleographer the significant division is not the founding of Constantinople in 330 but the 5th century, from which a few firmly dated texts survive. At its close a large, exuberant, florid cursive is found fully established for documents; in the 7th and 8th centuries it slopes to the right, becomes congested, and adopts some forms that anticipate the minuscule hand. A favourite informal type of the 6th century is shown in

Biblical uncial

Biblical uncial. Dioscorides herbal, AD 512 (Vienna, Österreichische Nationalbibliothek, Med. Gr. 1).

an acrostic poem by Dioscorus of Aphrodito; it bears a clear relationship to the Menander *Dyskolos* hand, which was probably written in the later 3rd century AD. Similar pairs could be found to illustrate the continuity in transformation of the biblical uncial and Coptic styles. The latest Greek papyrus from Egypt is not later than the 8th century. There is a considerable lapse of time before the history of Greek writing resumes at Byzantium. (E.G.T.)


Informal Byzantine book hand of the 6th century. Acrostic poem by Dioscorus of Aphrodito, 6th century AD (British Museum, P. 1552).

The 8th to 16th century. To judge when and where a Greek manuscript was written is as difficult in this as in the earlier period, but for different reasons. The material for study is admittedly more extensive; manuscripts produced in the Middle Ages and Renaissance have been preserved in very large numbers (more than 50,000 whole volumes survive, of which probably 4,000 or 5,000 are explicitly dated), and they include work from most parts of the Byzantine Empire as well as from Italy. The difficulty of the paleographer lies in the essential homogeneity of the material, which is largely the result of the conditions in which the manuscripts were produced.

The fully developed Byzantine Empire of the 8th to the mid-15th centuries was extraordinarily uniform in its culture. Its contraction in space after the Arab conquests of the 7th century, which cut off the more distant and ethnically differentiated provinces of Syria, Palestine, and Egypt, made it a relatively compact geographical entity. The continuity and comparative stability of a single empire not divided into distinct national states such as evolved in the West resulted in a strength and unity of tradition of which the Byzantines were always conscious and that shows in their habits of writing no less than in their literature and art. Distinct local styles and sharp breaks in ways of writing in different periods cannot, therefore, be looked for; characteristics that may be specially typical of one period come in gradually and disappear equally slowly. A more potent factor than date or place in producing divergencies in the style of writing is the purpose for which a manuscript was designed and what type of scribe wrote it.

Late uncial, 9th to 12th century. There is a gap in the evidence covering the 7th and 8th centuries, because of the Arab conquest of Egypt, the perpetual wars on all fronts in the 7th century, and the iconoclastic struggle among Eastern Christians during the 8th and early 9th centuries, so that no literary texts (and very few others) have survived that can actually be dated to this period.

During this time the evolution of writing in capitals (not very aptly named uncial) probably continued toward a greater formality and artificiality. But this natural tendency was hastened by the introduction and spread of minuscule as the normal way of writing, after which the **Change of** purpose of uncial changed completely. From an everyday **purpose of** hand in which all books were naturally written, it became **uncial** a ceremonial hand used only for special copies and therefore grew increasingly stylized and artificial. In the 9th century a still elegant style was used for both patristic and classical works in splendid volumes destined for the imperial library or for presentation copies, such as the copy

Late uncial. Copy of Gregory of Nazianzus, AD 879–883 (Paris, Bibliothèque Nationale, Grec. 510, fol. 61ᵛ).

of Gregory of Nazianzus (Bibliothèque Nationale, Paris) made for the emperor Basil I between 879 and 883. By the 11th and 12th centuries, capitals were used only for liturgical books, mainly lectionaries, which had to be read in dimly lit churches; but the increasing tortuousness of the style must in the end have reduced its usefulness, and by about 1200 uncial was dead.

Earliest minuscule, 8th to 10th century. By far the most important development that took place during the 7th–8th-century gap was the introduction of minuscule. There is no incontrovertible evidence of how this came about, or where. What scraps of evidence there are (a few documents from the gap, a few sentences in lives of the abbots of Stoudion of that time, and the first dated manuscript written in true minuscule) point to its development from a certain type of documentary hand used in the 8th century and to the likelihood that the monastery of the Stoudion in Constantinople had a leading part in its early development. **Reasons** Though its origins are obscure, the reasons that led to **for the** its introduction and rapid spread are obvious: the state **rapid** of poverty resulting from wars and persecutions coincided **spread of** with a shortage of papyrus after the Arab conquest of **minuscule** Egypt in the middle of the 7th century, and these factors combined to induce a search for a more economical use of the relatively expensive vellum; the polemics of the iconoclastic controversy demanded a speedy, informal style of writing; and, finally, when peace was restored in the middle of the 9th century, the revival of learning, with the reorganization of the university, brought the need for multiplying plain workmanlike texts for scholarly purposes.

The earliest dated example of true minuscule (and it is probably one of the oldest extant examples altogether) is a copy of the Gospels written in 835 (Leningrad Library), probably in the monastery of the Stoudion. Here are found all the characteristics of the earliest minuscule, which is called pure minuscule because there is as yet no admixture of uncial forms, except occasionally at line ends. The letters are even and of a uniform size; letters are joined or not joined to each other according to strict rules, sometimes by ligatures in which part of each letter is merged in the other, but not to the extent of distorting the shape of either letter. There is no division between words, for the divisions are only those that arise from the rules for joining or otherwise of individual letters, and at this stage any letter that can be joined to the next one nearly always is joined to it. Breathings are square, either

⊢ ⊣ or └ ┘, and accents are small and

neat; abbreviations are very few, usually confined to the

established contractions for *nomina sacra* (the names and descriptions of the Trinity and certain derivatives), omitted *v* at line ends, a few of the conventional signs

for omitted case endings, and $\underset{\backprime}{S}$ sometimes for *καὶ*. The

writing stands on the ruled lines or is guided by them.

Absolutely pure minuscule did not last long. Gradually, uncial forms of those letters that had specifically minuscule forms began to be used alongside the minuscule forms: *λ* was the first to appear, followed by *ξ* and then *κ*, all by the end of the 9th century. Then from about 900 onward, *γ*, *ζ*, *v*, *π*, and *σ* were used regularly, while *a*, *δ*, *ε*, and *η* were used sometimes. Not before about 950 were *β*, *μ*, *v*, *ψ*, and *ω* used, and still comparatively rarely. But by the end of the 10th century, the interchangeability of all uncial and minuscule forms is complete, though all the alternative forms are not necessarily found in any one manuscript. Perhaps the earliest dated manuscript with any uncial form in it is of 892/893 (Mt. Sinai, St. Catherine, MS. 375 + Leningrad, Bibl. Publ. MS. 343, Chrysostom), but pure minuscule continued to be used, in probably the majority of manuscripts, up to 900 and thereafter mainly in provincial manuscripts until the last dated example in 969 (Metéora, Metamorph. MS. 565, John Climacus). Besides the intrusion of uncial letters, some other characteristics of the earliest minuscule were modified during the 10th century. Rounded breathings, '', are first found in manuscripts of the last half of the century, interspersed with square ones. From about 925 the practice of making the writing hang from the ruled lines began to prevail. Although in most manuscripts abbreviations were confined to a few forms used at line ends only, a few copies dated in the last part of the century used nearly all the conventional signs.

In spite of these developments—the gradual disappearance of pure minuscule and the other changes that accompanied it—the same general styles of writing persisted until about the end of the 10th century. Broadly considered, three styles can be distinguished during this period. There is a rather primitive-looking, angular, cramped style that may perhaps be associated with the Stoudion monastery, in which a certain number of mainly patristic texts were written *c.* 880–*c.* 980 (*e.g.*, Paris, Bibliothèque Nationale, MS. grec 1470, a Menologion of 890). Second, there is a plain, neat, workmanlike style (seen in a commentary on Gregory of Nazianzus copied in 986 that is preserved in the Bibliothèque Nationale at Paris), which continued in use at least until the end of the 10th century. In it were written several of the important manuscripts that

are now the oldest texts of some ancient Greek authors (for example, Aeschylus, Sophocles, Aristophanes) but unfortunately not explicitly dated. Third, a consciously elegant, even mannered, style was used in books produced for the imperial library or for wealthy dignitaries, but it is not found before the early years of the 10th century (as seen in a copy of Basil on Isaiah in the Bodleian Library that is dated 953). All of these styles, which have numerous variations and are by no means always distinct from one another, are found at least until the end of the 10th century. Their one common characteristic is a crispness and individuality that clearly distinguishes them from writing of the next period.

Formal minuscule, 10th to 14th century. From about the middle of the 10th century, a smoother, almost mechanical appearance can be noticed in an increasing number of manuscripts; the hands seem more stereotyped, less individual. They are not immediately distinguishable from the plainer styles of the earlier part of the century, and their evolution during the next four centuries was very gradual. A few distinct types can be singled out from time to time. A bold, round, heavy liturgical style, fully established in the 11th century, was one of the most enduring types (*e.g.*, British Museum, Add. MS. 19,352, a psalter of 1066); it became more and more stereotyped and mechanical until, in the 15th century, a branch of it was transplanted to Italy.

The style most widely used for biblical and patristic texts from the end of the 10th century, probably mainly in monastic houses in Constantinople, was one with plain, neat, rounded letters; this style became known as *Perlschrift* from its likeness to small, round beads strung together. A very plain, businesslike, rather staccato style was used in manuscripts with musical notation, most commonly in the 12th and 13th centuries (*e.g.*, Leningrad, Bibl. Publ. MS. 789, a sticheron of 1106).

Manuscripts written outside Constantinople are recognizable, if at all, usually by a rougher, provincial appearance. Only two styles can be assigned with any certainty to a specific provincial centre. One, a small unpretentious hand used by St. Nilus, the founder of numerous monasteries in southern Italy at the end of the 9th century, was used for a time by others in that area (*e.g.*, a copy of the works of Dorotheus made by Nilus in 965). In the heyday of the reorganized Greek monasteries there in the 12th century, another elegant, rather mannered style, which almost certainly had its origin in Constantinople, is nevertheless found in manuscripts known to have been written in southern Italy and Sicily (*e.g.*, Paris, Bibliothèque Nationale, MS. grec 83; Gospels copied in Sicily in 1167).

These particular styles, however, are not really as typical of the period as the less distinctive plain hands in which the majority of the manuscripts are written, at least in the 11th and 12th centuries (*e.g.*, a collection of canon law copied in 1042 in the Bodleian Library).

The comparatively uniform type of writing of which all these were minor variations was remarkably enduring and widely dispersed, but, from the 11th century onward, certain changes may be observed that help to date manuscripts written in all types of formal minuscule. One change in its general appearance may be noticed as the 12th century advances: an increasing lightness of touch and a lessening of the closely knit, rather thick appearance that is characteristic of the 11th century. But the most noticeable change in this period is the breakdown in the evenness and regularity of the writing, which is partly attributable to the influence of documentary and the later

personal hands. It is not, however, entirely so attributable, for a tendency to enlarge some letters out of proportion to the size of the rest is seen in a small way in some of the more personal hands of the earliest period. But it is rare in formally written manuscripts, only gradually becoming more general until, in the 12th and 13th centuries, it is the most noticeable feature of even the most formal hands (*e.g.*, a synaxarion, or a short narrative of a saint's life, copied probably in 1329). In the 14th century and later there was a return to less flamboyant ways with the tendency to imitate earlier models more closely, but the habit of enlarging some and diminishing the size of other letters never died out.

In the actual forms of letters used in these formal styles, there was practically no change; very occasionally, from the end of the 10th century onward, one of the "modern" forms of letter normally confined to personal hands found its way into a formal manuscript. Much the same is true of ligatures. The tendency from the 11th century onward is to use ligatures and to join letters less automatically than in earlier times. The permissive rules and most of the forms remain unchanged, for, already in the 10th century, most of the distorting forms (notably those in which the

ε is represented only by a C-shaped stroke; *e.g.*, for

$\sigma\varepsilon$) were well established, and in formal manuscripts these, with the earlier forms, continued in use until they were illogically taken over by the first printers of Greek. Time did, however, gradually increase the tendency to join letters by insetting them in or superimposing them upon each other. Abbreviations were even more conservatively used, only the oldest conventional forms being admitted, and often only a very few and those only at line ends.

The rule that the writing should hang from the ruled lines, already applied in most manuscripts by the mid-10th century, became invariable by the middle of the 11th. Square breathings (used indiscriminately among the round ones) were gradually eliminated, though they did not completely disappear from formal manuscripts until the middle of the 12th century. The practice of joining accents with breathings and also with the letters to which they belonged spread from personal hands to formal writing in the 13th century, but it was far more often avoided altogether.

Apart from the actual writing, one development is common to all manuscripts written in this period: the use of paper instead of vellum, which occurred first perhaps in the late 11th century and was common by the 13th century whenever economy was a major consideration.

These are the main criteria by which a formally written manuscript can be assigned to an earlier or a later part of this period. But the problem of distinguishing different styles and their dates, and their places of origin, remains most difficult for these Greek manuscripts.

Personal hands, 12th to 14th century. From the beginning of minuscule, there were obviously educated individuals who occasionally copied texts for their own use in a formal hand that nevertheless had a distinctive personal flavour; indeed, professional scribes occasionally used a less formal style than usual. Several dated examples of this type of hand survive from the 10th, 11th, and early 12th centuries, but they are rarities. Toward the end of the 12th century, however, the prosperity and comparative stability of the Comnenan age (named from the dynasty of Byzantine emperors bearing the name Comnenus), with its brilliant literary and artistic achievements, gave way to increasing internal chaos and the hostile encirclement of

Byzantium that was a prelude to the Fourth Crusade and the sack of Constantinople by the Western powers in 1204. Scholars perhaps already felt the pinch of poverty, which naturally grew greater during the exile of the Byzantine court (1204–61) and culminated in the economic crises of the 14th century.

Certainly, a change in writing habits began slowly to take place. Instead of commissioning professional scribes to copy manuscripts, some scholars began to make copies for themselves, and, in place of the smooth, mechanical styles of the professionals, they used the sort of writing that they presumably already used for personal notes. This was an adaptation (for greater clarity) of the type of writing that had been standardized in official documents from the beginning of the Byzantine period. Its chief characteristic was the greatly exaggerated size of certain letters or parts of letters, particularly letters with rounded bows such as β, ε, ζ, θ, κ, ξ, o, v, φ, and ω, and the excessive size of these letters is made to look even more unbalanced by some exceptionally small forms of, for example, η, ι, v, or ρ. This essentially unbalanced, "wild" look was transplanted to literary manuscripts written by scholars for their own use.

Along with this exaggerated contrast in size between letters, they took from the documentary hands several forms of letters that had gradually evolved from the originally common forms of both hands. In the 12th century the new scholarly hands began to use $\mathbf{6}$ with separate small bows; ε , with a broken back; η , which had lost its high first stroke; and V , which had dropped its first long downstroke; and, by the end of the 13th century, ς , with a short embryonic tail. The old forms of ligature were kept basically the same but, in some cases, were reduced to a barely recognizable minimum (*e.g.*, $\mathcal{G}$ or 4 for $\varepsilon\iota$) and, in others, distorted by the general flourishing tendency of the script (*e.g.*, ω for $\varepsilon\pi$). Abbreviations were naturally used with great frequency in all positions; the ancient conventional signs for suppressed syllables, which had acquired rounded and more flourished shapes, were used alongside a certain amount of "arbitrary" abbreviation in which a large part of a word was omitted and replaced simply by a general sign that some abbreviation had taken place.

Accents and breathings joined with each other, with letters, and with abbreviation marks are found earlier and

more frequently in scholarly than in formal manuscripts. The only exception to the rule of round breathings in this type of manuscript is in cases of deliberate archaism such as practiced by Demetrius Triclinius (died *c.* 1340).

One of the earliest datable examples of these scholarly productions is the copy of his commentary on the *Odyssey* (Biblioteca Nazionale Marciana, Venice) written *c.* 1150–70 by Eustathius, the scholar-archbishop of Thessalonica. In the 13th century the exaggeration of specially round features reached its height (*e.g.,* in a copy of Euthymius Zigabenus on the Psalms, of 1279 [Oxford, Bodleian Library, MS. Roe 7]), while, in the 14th century, the tendency, as in the formal styles of writing, was toward less ebullience and exaggeration, and the writing of scholars such as Triclinius is compact and sober (*e.g.,* his copy of Aphthonius and other grammatical works, of 1308). For these hands the problem is not to discover centres of writing or styles for different uses but to identify the hands of individual scholars.

The Italian Renaissance. By the end of the 14th century, Italian scholars were learning Greek, and they were bringing back Greek manuscripts from Constantinople. At this time Greek scholars had also begun to teach in Italy. The Greek that the earliest Italians learned to write was a clear, simple style taught originally by Manuel Chrysoloras (died 1415). But, although they copied a number of manuscripts for themselves in this hand, the style had no influence beyond their small circle. Before long, Greek scribes began to go to Italy, and both scholars and scribes arrived in increasing numbers as the Turks pressed in around the Byzantine capital until it finally fell in 1453. They brought with them, naturally, the two styles of writing that had persisted throughout the history of the empire. On the one hand, professional scribes such as Joannes Rhosus (died *c.* 1500), the majority of them from Crete, copied an astonishing number of manuscripts in the formal, now glib and stereotyped "liturgical" style of writing (*e.g.,* British Museum, Harl. 5658, an *Odyssey* copied by Rhosus in Rome in 1479). On the other hand, scholars such as Janus Lascaris continued to write in a mannered personal style (*e.g.,* a letter of Demetrius Chalcondyles of 1488 in the Biblioteca Apostolica Vaticana, Vatican City).

It was on the scholarly hands that Aldus Manutius and other early Italian printers of Greek based their types. But perhaps the most enduring was that of a group of Cretan scribes who were employed by Francis I in his library at

Fontainebleau. The writing of one in particular, Angelus Vergecius (*e.g.,* his copy of Manuel Philes made in 1564 in the Bodleian Library), was used as a model for the French Royal Greek type, which has influenced the form of Greek printing down to the present day.   (R.Ba./Ed.)

LATIN-ALPHABET HANDWRITING

Ancient Roman styles. *Rustic capitals.* The Latin and vernacular handwriting of western Europe descends in an unbroken line to the present day from the point at which it is first observed, in the 1st century AD. The script used throughout the Roman Empire at that time for books and occasionally for formal documents is known as rustic capitals. The pen was cut with a broad end and held so that its thickest strokes fell at an oblique angle to the line of writing, and it was lifted several times in the formation of a single letter. The rustic capital alphabet is "majuscule," in that all the letters are contained between a single pair of horizontal lines. The use of this elaborate script, whose letter forms were the natural outcome of using a broad pen held obliquely, was extended to certain sorts of inscription on stone and other materials, and it is called rustic only by comparison with the magnificent square capitals characteristic of Roman imperial inscriptions, whose forms were governed by the use of the chisel. Square capitals were seldom used in manuscripts except for titles. Rustic capitals continued in use for literary manuscripts until the 6th century, especially for texts of Virgil, but thereafter they appeared only in titles, down to the 12th century.

Cursive capitals. The business hand of the 1st century, used for correspondence and for most documents, private and official alike, is known as cursive capitals. Here the pen, cut to a sharp point, was held at the same oblique angle but was lifted less often, and this "cursive" handling automatically produced new and simpler letter forms such as ∂ (two strokes) for D (three strokes) and $\digamma$ (two strokes) for E (four strokes). Some of these new letter forms are "minuscule," in that parts of them ascend or descend beyond the body of the letter (h, q) instead of being confined between a pair of lines, as in the majuscule rustic capitals (H, Q).

(margin note: Roman business hand)

From the 2nd to the early 4th century, parchment was replacing papyrus as the standard writing material for books, and the codex was replacing the roll as their standard form. The evidence that survives from this period, during which biblical and other Christian literature was beginning to be copied extensively, is fragmentary, and its interpretation is still controversial. The main line of development, however, is clear enough. The elaborate letter forms of rustic capitals, with their numerous pen lifts, began to be abandoned, and experiments were made with new book hands in which the simplified letter forms of cursive capitals were written with a broad pen, sometimes held obliquely in the traditional way and sometimes held "straight," so that its thickest strokes fell at right angles to the line of writing. It was probably the use of a straight pen that produced, for example, the conversion of cursive capital ∂ (axis oblique) into the fully minuscule d (axis vertical).

Uncials, half uncials, and cursive minuscule. At the end of this period of transition, in the 4th and 5th centuries, when the evidence becomes more abundant, two new book

hands and a new business hand are found in use. The older of the book hands, called uncials (the name dates only from the 18th century), was originally written with a slightly oblique pen; but, from the 6th century onward, a straight pen was used, and the hand began to look rounder and more contrived. Although it incorporates several of the cursive letter forms (δ, ε h) of cursive capitals and has two forms peculiar to itself (α, m), it also preserves certain forms, such as B, N, R, S, which differ only a little from the forms of rustic capitals; and all three kinds of letters are treated as majuscules, being confined as far as possible between one pair of lines.

From the 4th to the early 7th century, most Christian books—biblical, patristic, and liturgical—were written in the uncial script, and even for pagan literature it almost entirely superseded rustic capitals. It survived the collapse of the Roman book trade. And, after the 6th century, when the production of all books, pagan as well as Christian, was taken over by the church—notably by the monasteries, such as the Vivarium founded in southern Italy by Cassiodorus, a scholar whose aim was to perpetuate Roman culture, and the houses that observed the Rule of St. Benedict—uncial script survived in many centres, especially for biblical and liturgical texts, down to the 9th century. Thereafter, like rustic capitals, uncials were used only for titles, and they, too, disappeared in the 12th century.

The younger of the two new book hands is called half

uncial. This script was less popular than uncials and never broke their monopoly of biblical and liturgical texts, although like them it was still being written in the 8th century and even, as a display script for certain purposes, in the 9th. The artificial name half uncial tells nothing about the origin or nature of the script. It differs from early uncials in being written with a perfectly straight pen. One letter (N) remains more or less unchanged from the capital form, but the rest of the alphabet is cursive in origin. The letter forms that differ most from uncials are *a, b, d, g, m, r, s;* and the alphabet as a whole is frankly minuscule, since no attempt is made to confine it between a single pair of lines.

The new business hand of the 4th century and after is known as cursive minuscule. Like cursive capitals, it was written with a pointed pen, but the pen was held more or less straight. It, too, is a frankly minuscule alphabet and uses basically the same letter forms as half uncials, although the frequency in cursive minuscule of ligatures between letters tends to conceal the fundamental likeness between the two hands.

Cursive minuscule as a business hand

Cursive minuscule. Avitus of Vienne, 6th century AD (Paris, Bibliothèque Nationale, Lat. 8913 and 8914).

The letter forms that distinguish cursive minuscule and half uncials from rustic and cursive capitals and from uncials were evolved during the obscure period between the 1st and 4th centuries. The question of whether these forms were evolved in the sphere of the book hands or of the business hands is still undecided, but, whatever their origin, their importance for the subsequent history of European handwriting is paramount. They provided the material on which the Carolingian minuscule, first developed in the late 8th century, was based; and that script dominated Europe, in spite of severe modifications, until the end of the Middle Ages. Only in one other period were new letter forms evolved, between the 13th and the 15th centuries, in the group of scripts known as Gothic cursives; and the influence of these late innovations was ultimately cancelled out, thanks to the revival of Carolingian minuscule in a pure form by the Italian humanists at the beginning of the 15th century.   (T.J.Br.)

The Anglo-Celtic and other "national" styles (5th to 13th century). From the 5th century the relaxation of imperial Roman authority brought on a reassertion and growth of native cultures—that is, wherever the people were not wholly occupied in a savage struggle against barbarians for mere existence. The most isolated places, such as the province of Britain, responded strongly to this opportunity and at the same time were able to conserve important elements of the Roman civilization. With Ireland, which was never under occupation by the legions, it offered during Europe's darkest age comparative peace and shelter for the development of the richest and most original of book styles.

The Insular manuscripts were produced at monasteries that were often on a barren rock in the sea or at an equally inaccessible site. According to tradition, the earliest centre of Christian learning in Ireland was established by the Romano-British apostle St. Patrick (fl. 5th century). A great successor, St. Columba, or Columcille (c. 521–597), whom legend credits with divine scribal powers, founded monastic houses at Derry and Durrow and then journeyed

Anglo-Celtic monastic centres of manuscript copying and illumination

to the Inner Hebrides to found one on the lonely island of Iona c. 563. St. Columban, another Irish missionary, in much the same period was founding monasteries on the Continent: c. 590 in Gaul (modern France) the Burgundian centre Luxeuil, from which Corbie in Picardy was organized, and St. Gall in Switzerland and Bobbio in Italy about the years 612 to 614. From Iona a daughter house was founded in 635 on St. Cuthbert's holy isle of Lindisfarne just off the Northumbrian coast of England. To the south the Northumbrian monk, later abbot and saint, Benedict Biscop (c. 628–689/690) established the twin monasteries of St. Peter at Wearmouth in 674 and St. Paul at Jarrow in 682. He endowed them with splendid collections of books and pictures gathered during repeated visits to Rome, so that, in the late 7th and early 8th centuries, they constituted the most flourishing centre of Christian scholarship in western Europe and the meeting place of Hiberno-British and continental influences.

For the fine books made in the Anglo-Celtic centres, the majuscular script called Insular half uncial was deemed suitable rather than the pointed, more cursive Irish minuscule used for documents and vernacular texts. There is a high degree of conformity, attesting to their stylistic maturity, among such manuscripts as the Book of Kells (Trinity College, Dublin) and the Lindisfarne Gospels (British Museum), individual as they are in detail and ornament. After all, there is room for infinite variation where, in one-quarter of a square inch, 158 interlacements have been traced unerringly—by angels, it is said. The Book of Kells, Codex Cenannensis to paleographers, was probably produced at Iona around 800. It has 339 leaves, 13 by 10 inches (33 by 25 centimetres) of noble script in single column, jet black on well-made parchment, through which runs the most spirited and colourful of ornamentation, ranging from the red-dotted outlining of letters, which is as much a feature of the style as the wedge-topped ascenders, to the wildly extravagant full-page initials at the opening of Gospels. The other masterpiece of Anglo-Celtic calligraphy and illumination, the Codex Lindisfarnensis, was written in honour of St. Cuthbert shortly after his death in 687. It displays the same lively inventiveness, the love of fantastic animal and bird forms (zoomorphs), intricate interlacing, and even, rhythmic script, set off by generous margins.

The earliest of all extant manuscripts of the Insular style is the *Cathach* ("Battler") of St. Columba (Royal Irish Academy, Dublin), who, according to legend, wrote it himself and, in the judgment of scholars, may actually have done so. Housed in its *cumhdach* (a sort of ark), it was carried into battle to ensure victory.

Besides the proud witness of such books as these to the Anglo-Celtic contribution, there were also the productions of continental centres influenced by St. Columban and his disciples, as well as books mainly in the Roman tradition but carrying the unmistakable sign of Insular influence. For instance, there are three that scholars believe were written in the 7th century at Bobbio, Italy, in the monastery of St. Columban. They are Codex Usserianus Primus, now a treasure of Trinity College, Dublin, and two manuscripts preserved in the Biblioteca Ambrosiana, Milan, known as

Insular minuscule. *Historia ecclesiastica*, by Bede, 8th century (British Museum, Cotton Tiberius C.11).

Codex Ambrosianus C.26 sup. and Codex Ambrosianus D.23 sup. There is another, Codex Amiatinus (Biblioteca Medicea-Laurenziana, Florence), of 1,030 leaves measuring 20 by 13½ inches (51 by 34 centimetres), made in Northumbria in the 8th century. It is continental Roman in style with no concession to the Insular habit of ornamentation. This is understandable, for it was designed for presentation to the pope.

Though the Insular minuscule was ready to hand, the majuscular half uncial as the senior script was always given the place of honour and the preference for the fine Latin books of the Anglo-Celtic monasteries. Nevertheless, by the 8th century the minuscule was developing into a disciplined book hand, as seen in the copy of Bede's *Historia ecclesiastica* (c. 731; Cambridge University Library). The spiky, ligatured, compactly written style migrated early to the Continent and, by the beginning of the 8th century, was at home in the Anglo-Saxon foundation of Echternach, in Luxembourg. Fulda and Würzburg, in Germany, were other important centres abroad of Insular culture and book production in this style.

The Merovingian, in France, and the Visigothic, in Spain, are two more varieties of minuscular script that grew out of Latin cursive after the withdrawal of the Roman authority. In the Luxeuil monastery, in Burgundy, the minuscule attained in the 7th century the characteristics of a fine book hand but for only a short period, when the reforms under Charlemagne took effect. In the Iberian Peninsula the Visigothic style was in use from at least the 8th to the 12th century. It has the verticality of emphasis that is common to the other hands out of the same cursive background, when deliberately written, with weighted ascenders carefully topped by flat serifs.

The southern Italian script of the style called Beneventan, nurtured in the motherhouse of the Benedictine Order at Monte Cassino, was the "national" hand that rose to the status of calligraphy and held its position well into the 13th century, an active literary life of more than 500 years. This type of script has a peculiar jerky rhythm and retains individual cursive forms, which, together with the abundance of abbreviations and ligatures, make reading quite difficult.

Merovingian and Visigothic scripts

Beneventan script. Exultet Roll from Monte Cassino, Italy, late 11th or early 12th century (British Museum, MS. 30377).

Carolingian reforms in the scriptorium (8th and 9th centuries). The literary reforms carried on in the latter part of the 8th century and early 9th century by order of the Holy Roman emperor Charlemagne set the highest of standards for the making of books throughout his Western empire. The extensive educational program, looking forward to new authorized versions of the Vulgate, the missal, and other liturgical works, he placed in the charge of the learned English cleric Alcuin of York. The Emperor persuaded Alcuin to leave his position at the head of the cathedral school of York and the excellent library he had gathered there, first to become master of the palace school at Aachen, then at Tours as abbot of St. Martin's to conduct the literary activities centred at the well-established scriptorium (writing room) there.

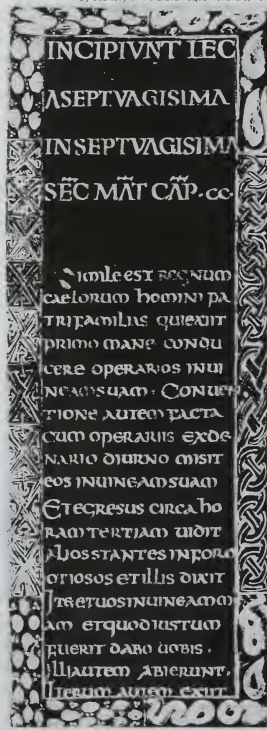
Contributions of Alcuin

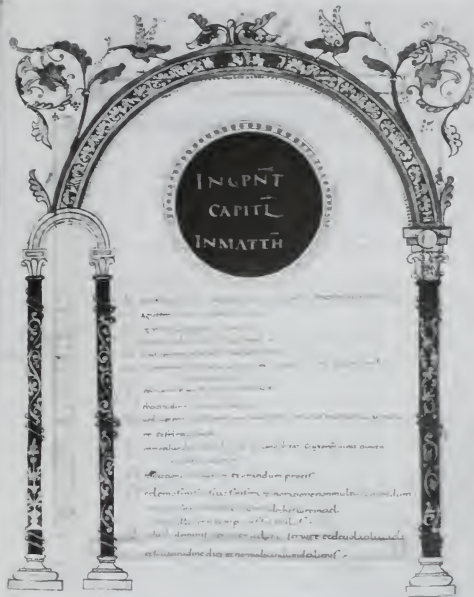
Before taking up the abbacy in 796, Alcuin was responsible for, or at least inspirer of, the most precious of Carolingian codices, the so-called Golden Gospels. These were a series of illuminated masterpieces written mainly in gold and often on purple-stained vellum. The most famous is the Godescalc Gospels (Bibliothèque Nationale, Paris), written before 783 for Charlemagne, the body of the text in uncials and the dedication in Carolingian minuscule. The most luxurious is the Saint-Médard Gospel Book (Bibliothèque Nationale), written entirely in gold uncials and illuminated with full miniatures, initials, etc., in gold and silver on purple ground.

Alcuin carried forward the work of the St. Martin scriptorium in the spirit of a true classical renascence. Each variety of traditional letter form was studied with a view to finding its norm by careful comparison with archetypes in ancient monuments and books. Thus, the square capitals, at the top of the hierarchy of scripts, were modeled on Augustan inscriptions. For rustic capitals (*capitales rusticae*), the reformers adopted the style of those used for the text of such fine old codices as the Virgil fragment now in the Vatican. The roman uncial was restored to its simple dignity, as in well-made books of the 6th century, and the minor, or half, uncial was likewise restored to the plain elegance of that earlier period, after the degeneracy of the 7th century.

Carolingian minuscule

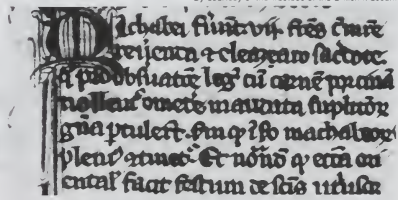
The model for the most valuable and characteristic of all the Alcuinian contributions, the Carolingian minuscule, has never been precisely determined. It may well have been a local variety of cursive or, more probably, a mixture of half uncial and cursive, in which Alcuin discerned the possibilities of his clear, round, flexible but disciplined script, comfortable to both scribe and reader. For, as regularized at the scriptorium of St. Martin, the minuscule was written with the shaft of the pen pointing somewhat to the right instead of straight back over the shoulder; though the letters were formed deliberately, even and round, stroke by stroke the same way every time by rule, the writing brought relative ease for the hand and eye. With the years some cursive features became more prominent—*e.g.*, a tendency nearly to join certain letters and an occasional hint of "italic" in the slightly sloping, even, well-spaced lines. The incipits (the opening words of the text) were celebrated by means of display letters and a decorative initial that might come from any one of a number of sources, including Insular, Byzantine, and Merovingian scripts. Otherwise, the classic calm was maintained. The crowning achievement of the Tours school of scholars, scribes, and artists was reached in the mid-9th century, under Alcuin's successors, in the Gospels of Lothair (Bibliothèque Nationale).

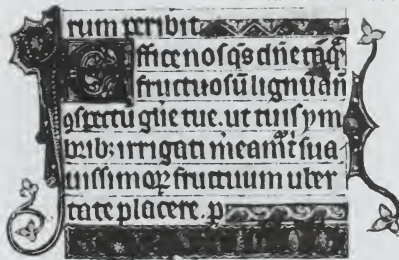
There are observable variations among the different Carolingian schools, but these are generally in small details. The most surprising departure is the Utrecht Psalter (University Library, Utrecht), written at Rheims, in rustic capitals and illustrated with fluent pen drawings in the Hellenistic fashion. Apparently, the whole work was devotely copied in the 9th century from an old model.


Uncial script. Godescalc Gospels, before 783 (Bibliothèque Nationale, Paris).


Gospels of Lothair, c. 850 (Paris, Bibliothèque Nationale, MS. Lat. 266, fol. 19).

The black-letter, or Gothic, style (9th to 15th century). Carolingian minuscule remained the unrivaled book hand of western Europe through the 9th century, or nearly so. Then a trend away from the official imperial standards set in. It can be observed progressing in the manuscripts written at St. Gall, in Switzerland, near the end of the 9th century and during the 10th. There is a tendency toward lateral compression of the letters. This begins as the natural result of an easier motion of the pen held with the shaft out to the side rather than pointing back over the right shoulder. Scribes learned to cut the pen's writing edge obliquely so that it would be parallel to the top of the page even though the shaft was held in the slanting position, yielding a perpendicular stroke of maximum width. They were led on by the attractive novelty of bolder and bolder contrasts that eventually were to appear to the eyes of the Italian humanists in the Renaissance so brutal as to deserve the bad name of Gothic. Nevertheless, the more condensed, compact writing allowed significant economies in the amount of time taken in writing the books and the quantity of materials used and, therefore, in the cost of finished manuscripts.

Black-letter style of increasing density deepened the


Gothic book hand. *Legenda aurea* by Jacobus de Voragine, 1312 (British Museum, Add. 11,882).


"colour" of the page and imparted to the northern, advanced, formal variety of book hand a matted aspect, or fanciful likeness to woven fabric, that gave rise to the name Textura. It is called by paleographers *littera textualis formata* or *lettre de forme.* As the script developed through the 11th and 12th centuries in Germany, France, and England, its curves broke into angles. During the 13th and 14th centuries the size of writing was generally reduced. It became stiffer, and though in the following century (its last of undisputed sway) the script regained size, the proportions were disagreeably narrowed, and the letters, in lines as rigid and mechanically perfect as a picket fence, have angles sprouting hairlines apparently added with a crow quill afterward. Of this species of formal black-letter book hand, two kinds are distinguished by paleographers. One stands flat and unserifed on the base line and is known as *textus prescissus.* The other is completed with square or diamond-shaped feet and is referred to as *textus quadratus.* Though the former, and earlier, variety has superior claims for the calligrapher, the latter is the variety that was carried into printing types and hence into much wider use. *Lettre de forme*

In Italy the writing during the same period took on weight, but the curves of comparable book script never became angles. The senior script there was the rotunda, heavy but not pointed. The form persisted for liturgical work both as writing and printing type until late in the Renaissance.

The north and the south had, of course, their other kinds of writing for court and business or personal uses. A cursive hand that flourished in France, Flanders, and England rose to favour in the 15th century as a vernacular book script. This *littera bastarda,* or *lettre bâtarde* as it is termed in the vexed nomenclature of paleography, for all its high style as attained in fashionable books, was close kin to the epistolary "running secretary" commonly written by northern Europeans and early American settlers until it grudgingly yielded in the 17th century to italic script. *Lettre bâtarde*

Textus prescissus by Brother Tickhill. "Beatus" page from the Tickhill Psalter, c. 1310. In the collection of the New York Public Library.

The scripts of humanism (14th to 16th century). Under the inspiration of the 14th-century Italian poet Petrarch, who started the collecting of ancient manuscripts, coins, medals, and other "antiques," the essentially literary movement called humanism engaged a group of scholars at Florence in the latter part of the 14th century and opening decades of the 15th. Their growing enthusiasm for antiquity led them on an ever-widening search for Latin books and ancient monuments, in order that they might restore the lost heritage of Rome. Classical authors written in the clear Carolingian minuscule with display lines in lapidary style (*i.e.,* in the style of ancient inscriptions cut on stone) appealed to them as though straight from the time of Cicero instead of from the 10th to 12th centuries. Reverently, Coluccio Salutati, the late 14th-century chancellor of Florence who followed Petrarch as leader of the movement, and his fellow humanists imitated the old script, which they spoke of as the *lettera antica* to distinguish it from the ordinary *moderna* black-letter style. *Lettera antica* and *moderna*

Two protégés of Salutati are credited with developing,

on the basis of these studies and experiments among old manuscripts, the two fundamental scripts of humanism. Poggio, at the very beginning of the 15th century, produced the round, formal writing that, after polishing by a generation of scribes, served the new art of printing as prototype of "roman" fonts. He promptly followed up this achievement by introducing into his manuscripts the square capital letters as used on ancient monuments. Later in the century the rage for epigraphic inscriptions brought such enthusiasts as Cyriacus of Ancona, Felice Feliciano of Verona, and his fellow townsman Giovanni Giocondo into the field and, from Padua, Giovanni Marcanova, Bartolomeo Sanvito, and Andrea Mantegna. They compiled their researches in great *sillogi*, or anthologies, which, among other uses, gave calligraphers authoritative patterns for letter forms, ornament, and the correct spacing and placing of all display elements in their books. Feliciano, a calligrapher fond of ornament and fertile in invention, about 1460 first demonstrated how to construct the monumental roman capitals according to geometric rules.

Lettre bâtarde by Henri de Ferrieres. *Livre du Roy Modus et de la Reine Ratio*, c. 1435 (New York City, Pierpont Morgan Library, M.820, fol. 16ᵛ).

The second style of humanistic script appears earliest in the writings of Poggio's friend Niccolò Niccoli, who was also an accomplished scribe. His slightly inclined cursive, written with a fairly narrow rounded nib at a good rate of speed, was to be to the printers' "italic" what the Poggian hand became to their "roman." Niccoli's innovation employed movements and rhythms close to those of the ordinary black-letter cursive familiar in everyday affairs. Indeed the script contains a sprinkling of current black-letter mannerisms and lends itself similarly to the joining or tying together of letters. The special character of this *antica corsiva* results from the narrowing of the bodies of letters due to the rapid up-and-down movement of the pen, facilitated by its being held with the shaft pointing at an angle away from the shoulder instead of straight back,

Antica corsiva

producing this ✕, not ✛. As in italic fonts to this day, the form of *a* is distinctive; and *f, g, k,* and *ſ* (long *s*) are all more or less reminiscent of black-letter current habits. For his headings Niccoli preferred roman capitals "italicized" by a slight inclination to the right.

Both scripts were at once taken up and spread by other able scribes working at Florence in the first half of the 15th century, of whom the work of Giovanni Aretino, Giacomo Curlo, and Antonio di Mario, among others, is well recognized.

Poggio himself in 1403 had promptly carried his new script to Rome, where he later became papal secretary. Both scripts were devoted exclusively to the service of Latin literature, but there was a difference. Poggio used his hand as a calligrapher, while Niccoli used his as a copyist. The manuscripts of the former are set forth on fine parchment with meticulous care to formal details, such as even lines at the right-hand margin, and with handsome embellishment. Those of the latter are on paper, compactly and rapidly written, with attention to legibility and textual accuracy above all. There is an interesting parallel in the printed books of the following century. Ambitious

Humanistic scripts.

Renaissance folios are set in fine roman types, while the well-edited but cheap little student books are just as naturally set in italic.

Typographic printing displaced the copyists. At the same time printing gave impetus and new significance to the work of the calligraphers. They accepted the challenge of mechanized writing and for a while turned out the finest of humanistic masterpieces. In the late 15th and early 16th centuries the Paduan Sanvito and Pierantonio Sallando of Mantua, for instance, not only wrote the round humanistic script in a fashion worthy of the richest miniatures and illumination but also honoured the slender proportioned "italic" script by promoting it to a place in some of their proudest and most precious manuscripts.

Influence of printing

Sanvito's folio and octavo classics in the humanistic cursive are also celebrated for vellum pages stained purple, yellow, green, or salmon pink and for lines of inscriptional capitals alternating gold, blue, lake, purple, violet, and green. The *antica corsiva* perfected by 15th-century papal scribes for rapidly inditing briefs issued by the chancery also won its way as the chosen medium of polite correspondence. Thus, in the 16th century the versatile *lettera da brevi*, or *cancellaresca* (chancery cursive), lively yet disciplined, responsive to wide variety in cut of nib and speed of movement, attainable by the novice and gratifying to the adept either as book or epistolary hand, became a vehicle of the new learning throughout Christendom.

Cancellaresca, or chancery cursive

As written by the early 16th-century calligrapher and printer Lodovico degli Arrighi of Vicenza, the *cancellaresca* can range from eye-arresting contrasts of almost Gothic thick-and-thin strokes to a delicate, supple monotone tracery. The ascending letters, instead of terminating in serifs as with Sanvito or Sallando, now wave plumelike to the right, and the descenders are tending to balance them with a swing to the left. In 1522 Arrighi published at Rome his modest though revolutionary work *Operina da imparare di scrivere littera cancellaresca*. This, the earliest of printed writing manuals, or copybooks, held out to the public clear, simple directions with woodcut examples and invited everyone to learn in a few days how to write this fashionable hand for themselves. In effect, it announced the end of the era of the scriptorium and the beginning of the era of the writing master. Dependence upon attracting pupils and gaining a reputation with the public was thereafter reflected in the tendency to exploit novel or flashy scripts and extravagant ornament.

Writing manuals and copybooks (16th to 18th century). The Arrighi *Operina's* devotion to the chancery cursive is matched in single-mindedness only by Gerardus Mercator's *Literarum Latinarum* (1540). Arrighi's second publication, *Il modo de temperare le penne* (1523), is a more

Chancery cursive attributed to Pierre Hamon. *Navigation*, title page from the Harleyian manuscript, *c.* 1560 (British Museum, MS. 3996, fol. 1).

normal performance for the calligrapher, notary, printer, and erstwhile scriptor of apostolic briefs in the role of writing master. This book redresses the balance in favour of the popular scripts.

Arrighi's elder contemporary and possible mentor, Giovanni Antonio Tagliente, writing master to the Venetian chancery, published his *Presente libro* in 1524, two years after the *Operina;* and Giovanni Battista Palatino published in 1540 at Rome his *Libro nuovo d'imparare a scrivere.* Though Tagliente was master of an elegant *cancellaresca*—his "living hand" is displayed in a holograph supplication to the Doge and council of Venice, 1491—as well as of the black-letter hands, he was out-of-date and

prey to the vices of the old professional; *e.g.,* his chancery specimens include a page of script leaning excessively to the right, and facing it is a page of similar script leaning away to the left, almost equally hard to read and useless. Unlike the author's own hand in his 1491 supplication, the woodcut models here are acutely pointed. Palatino at the same time exhibits a rigid, sharp-angled *cancellaresca formata* in his excellent manuscript specimen (Bodleian Library, Canon. Ital. 196 fol. 44r), while his popular manuals offer relatively easygoing models for learners. In particular, the Palatino *cancellaresca romana* is a normal even-toned script, modest as to bulbed ascenders (*testegiatta*) and angle of inclination, displaying in its forms hospitality for *bastarda* variations (*i.e.,* Gothicizing *g, h, k, r*). The fact that Palatino's *Libro nuovo,* besides being the most complete, was the most widely disseminated of mid-16th-century books on writing bespeaks certain latitudinarian qualities along with marvellous virtuosity.

The propagation of the chancery cursive abroad was furthered by native manuals too. The Latin letters called italics were introduced into Germany by Casper Neff's *Thesaurium artis scriptoriae* (1549); into Spain by a disciple of Palatino, Juan de Yciar, in his *Recopilacion subtilissima* (1548); into France by Pierre Hamon's *Alphabet de l'invention des lettres en diverses escritures* (1561); and into England by means of *A Booke Containing Divers Sortes of Hands* (1570) by Jean de Beauchesne and John Baildon.

The pure Italian chancery hand was the favourite of court circles and humanist scholars through the second half of the 16th century. In England Roger Ascham, mid-16th-century schoolmaster to kings and queens, wrote and taught an exemplary *cancellaresca,* as did the late 16th-century Cambridge don Bartholomew Dodington. These and other educated Europeans, including Shakespeare, generally wrote the black-letter "running secretary." For their part, the writing masters, in striving to reach an ever larger public, increasingly emphasized the compromise script intended to bring learners already indoctrinated in the common Gothic cursive to command more readily the fashionable italic style. The *Opera nella quale si insegna a scrivere,* of Vespasiano Amphiareo (Albertacci), had already offered at Venice in 1554 models that combined the overdisciplined strokes of Palatino with elements of blackletter mercantile hands (*e.g.,* loops and running ligatures); to this hybrid *cancellaresca* that he claimed as his own invention, Amphiareo gave the accurate name of *bastarda.* Then Gianfrancesco Cresci of Milan, a Vatican scriptor, published his *Essemplare* (1560), to herald the oncoming Baroque and to reject vehemently the works and ways of Palatino and all his academic sort. He replaced their most stylish broad, chisel-bevelled nib and meticulous building up of disjoined strokes with a narrow, rounded-off pen flexible enough to respond to pressure and fluent in dashing off his much-inclined italic *bastarda* topped off

Cancellaresca formata by Giovanni Battista Palatino. Manuscript specimen book, *c.* 1550 (Oxford, Bodleian Library, MS. Canon. Ital. 196, fol. 44r).

dramatically with bulbous *testegiatta*. It is not too much to say that Cresci's script, with the handsome set of swash capitals (to borrow the typographic term for these forms), not only established a revolutionary front for 17th-century calligraphy but also contained the germs of 18th-century "copperplate" and even Spencerian scripts. Cresci was the first in Italy to take advantage of copperplate engraving, though Giuliantonio Hercolani's *Lo Scrittor Utile* (1574; plates engraved in 1571) was a close rival.

The principal French hands of the period were the national black-letter cursive called *lettre françois* or *financière*, which was commonly used in ordinary affairs, and the aristocratic *italienne bastarde*. In the Low Countries, examples of excellence are provided by Clement Perret in his *Exercitatio alphabetica* (1569), and by Jan van de Velde in his work *Spieghel der Schriftkonste* (1605), the fame of which was carried down through many generations of English penmen.

Italic *bastarda*. Letter by Gianfrancesco Cresci, 1572 (Vatican
City, Biblioteca Apostolica Vaticana, Lat. 6185, fol. 135 R).

In Britain and its empire, the *italienne bastarde* was largely disseminated through Edward Cocker's engraved copybooks and manuals. Known variously as the "new mixt current" or the "speedy à la mode," its concessions to the black-letter running secretary include the *e* looped at the top like a latter-day Palmer Method *o* and what has been termed the upside-down *r*, which is easily misread as *u* by humanistic eyes. Nevertheless, in the second half of the 17th century, italic writing won decisively. By the opening of the 18th century, a chastened, businesslike version was developed in London by John Ayres

and his younger contemporary writing masters eager to serve commercial demands. The small, narrow variety of Italian-French script, known as the Italian hand, was relegated to ladies' use as something suited to frail capacities, while the robust strain, called English round hand or "copperplate," was considered to dominate an epoch of trade supremacy.

Though the transition from black letter had been even more accelerated in the American colonies, Boston in New England was one of the last bastions of calligraphy in the trend toward countinghouse and commercial-college penmanship. The traditional foundations were laid solidly by the 18th-century writing master Abiah Holbrook, who raised a group of young Bostonian proficients at the South Writing School and left a fine manuscript, *The Writing Master's Amusement* (1767), in personal testimony.

Penmanship in colonial America

Copperplate, or English round hand. From *The Universal Penman*, Philip Hofer (ed.), engraved by George Bickham, 1743. Facsimile edition, Dover Publications, Inc., 1941.

As the 19th century advanced, the competition constantly mounted among systematists emphasizing the plain, practical business hand and decrying the "ornamental branches." Those who loved to flourish quill pictures of bounding deer or calligraphic portraits of national heroes were increasingly placed on the defensive. Certain religious sects clung to their heritage of individual styles of writing as an art. The Shakers, under the influence of visions, wrote and drew elaborate spiritual manuscripts. Most of these pieces that still remain are in the round hand and Spencerian scripts of their contemporary world. Other religious sects, such as the Moravians and Mennonites settled in Pennsylvania, produced out of their background old-country culture bold and handsomely coloured decorative pieces generally called Frakturs because of the script in which their so-called "Pennsylvania Dutch" is presented.

Revival of calligraphy (19th and 20th centuries). The revival of calligraphy at the end of the 19th century was part of an artistic revolt against the mechanization of life. About 1870 the English writer and artist William Morris had begun to concentrate attention on the ancient practice of scribes and to study with pen on parchment the means of achieving similar results. In this fashion he wrote out and illuminated a number of texts, humanistic and medieval, in the years before he took up similarly the study of 15th-century printing prior to establishing the Kelmscott Press. His searching inquiries and patronage led papermakers and ink suppliers, among others, back to forgotten standards.

Among those who heeded the message was Edward John-

Johnston**

ston. On the basis of the Morris investigations and guided
particularly by Sydney Cockerell, Morris' secretary, he re-
discovered how to cut and sharpen reeds and quills, how
to hold the chisel-nibbed pen so as to produce the kinds
of writing that had become familiar in his study of old
manuscripts, and every detail of how to make manuscripts.
In 1899 he began teaching in London, first at the Central
School of Arts and Crafts and, two years later, at the Royal
College of Art. His early pupils soon became esteemed
designers of lettering and influential calligraphers—*e.g.,*
Anna Simons, Eric Gill, Noel Rooke, Graily Hewitt, and
Percy Smith. In 1906 he published the basic manual
Writing and Illuminating, and Lettering, 500 pages pro-
fusely illustrated with his own and Rooke's drawings and
with reproductions from historic manuscripts. In 1910 the
book was published in Germany, where it supported the
work independently begun by Rudolf von Larisch in Vi-
enna and carried on by Rudolf Koch and Anna Simons.
Under the Nazi regime, the Gothic exponents enjoyed a
resurgence, but, after the war, such skilled young German
calligraphers as Hermann Zapf led the way back to roman
and italic script styles. Jan Tschichold's work has been
influential in the appreciation of classical letters for pres-
ent-day uses.

Art schools everywhere gradually followed the Royal Col-
lege of Art in offering courses in lettering and writing;
these, along with sound forms, instilled a sense of respon-
sibility to a rich heritage. Accordingly, type design passed
from the engineers into the hands of artists and calligraph-
ical scholars, such as Stanley Morison, Jan van Krimpen,

Akke Kumlien, Bruce Rogers, Frederic W. Goudy, Vic-
tor Hammer, Berthold Wolpe, and Warren Chappell. The
"freezing" of fine alphabets as font material stabilizes them
and multiplies their influence. The effects were not lim-
ited to the printed or manuscript page or to book covers
and jackets; all kinds of private and public markers and
memorials, addresses, diplomas, and even the politicians'
ubiquitous testimonial "scrolls" were touched by reform
or at least by some consciousness of shortcoming.

Though the United States was a decade behind Britain
in organizing an arts and crafts movement, four years be-
fore Johnston's book appeared a Boston architect, Frank
Chouteau Brown, brought out a surprisingly sophisticated

book, *Letters and Lettering: A Treatise with 200 Examples*
(1902). He praised Morris' initiative but wished for more
classical balance; he pointed to the neglect of italics and
gave them generous space, including specimens from the
Lucas 1577 *Arte de escrivir,* "letra del Grifo," *bastarda,*
and others. In 1905 *The Parable of the Prodigal Son,* fash-
ioned like a humanistic manuscript by William Addison
Dwiggins and printed from photoengraved plates, was of-
fered for sale. Dwiggins, as illustration for a talk on early
writing books, copied a page out of the 1542 Tagliente he
had picked up in Europe and passed out prints of it at
the Dec. 29, 1913, meeting of the Society of Printers—
thereby leading the revival of *cancellaresca.*

Edward Johnston's pupils, and their pupils, organized in
1921 the Society of Scribes and Illuminators, "zealously
directed toward the production of books and documents"
by hand and the advancement of the crafts of member
scribes, gilders, and illuminators. The program of this pro-
fessional group based in London is conducted by means
of lectures, publications, and exhibitions. In the 1930s
exhibits traveled to five American centres, as well as to
Paris and Copenhagen. Members representing the several
crafts have collaborated in the making of the rolls of hon-
our for the Royal Air Force and United States Air Force,
at St. Clement Danes Church, London. The society has

served as a model for similar activities abroad, notably the
organization in The Netherlands under the leadership of
Jan van Krimpen. In 1952 the British society, with Alfred
Fairbank as president, recognized the rising popular inter-
est in italic handwriting by instituting the Society for Italic
Handwriting, which soon attracted a large international
membership of teachers and amateurs.

In the United States individual enthusiasts and informal
groups fostered calligraphy outside the art schools. Ernst
F. Detterer in Chicago, who had lessons from Johnston in
1913, headed such a group at the Newberry Library for
many years and, when he died in 1947, was succeeded by
James Hayes. In Portland, Ore., the instruction and copy-
books of Lloyd J. Reynolds, a professor of art in Reed
College, had significant influence. For decades Paul Stan-
dard in New York practiced and preached *cancellaresca
corsiva* and saw the italic reform gain.

20th-
century
writing
manuals
and
copybooks Since Johnston a series of manuals and copybooks cen-
tring attention on handwriting improvement have pro-
ceeded from the espousal of the rather heavy humanistic
hand he admired to an italic that at least implies more
speed. The fullest and most practical work on the italic is
by Alfred John Fairbank, *A Handwriting Manual* (1932).
The author places before his book as frontispiece a page of
the *bastarda* of Lucas, *Arte de escrivir,* 1577. J.H. Benson's
The First Writing Book (1954) consists of the text and
examples of the Arrighi *Operina* translated and admirably
written out by the editor and furnished with practical clar-
ifications and notes. Since Johnston calligraphical research
and publishing activities have also produced a handsome
and scholarly shelfful of books on related forms, most
notably the Renaissance capitals. (Ra.N./Ed.)

EAST ASIAN CALLIGRAPHY

In China, Korea, and Japan, calligraphy is a form of pure
art. Chinese, Korean, and Japanese calligraphy derive from

Chia-ku-wen (Chinese shell-and-bone script), Shang
dynasty (18th–12th century BC). In the East Asian
Library, Columbia University, New York.

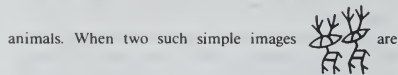
the written form of the Chinese language. Chinese is not
an alphabetical language; each character is composed of
a number of differently shaped lines within an imaginary
square. The early Chinese written words, like the Egyptian
hieroglyphs, were pictorial images, though not so close to
the objects they represented as in the ancient Egyptian
writing. Rather, they were simplified images, indicating
meaning through suggestion or imagination. These simple
images were flexible in composition, capable of developing
with changing conditions by means of slight variations.

Chinese calligraphy. The earliest known Chinese lo- Shell-and-
bone script
gographs are engraved on the shoulder bones of large
animals and on tortoise shells. The piece illustrated con-
tains a number of the early ideographs; each seems to
have been carefully composed before being engraved on
the bone. Although they are not entirely uniform in size,
the variations are not great. The figures must have evolved
from rough and careless scratches in the still more distant
past. This *chia-ku-wen,* or shell-and-bone script (18th–
12th century BC), is the earliest stage of development in
Chinese calligraphy.

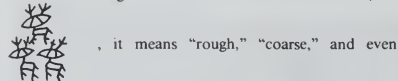
It was said that Ts'ang Chieh, the legendary inventor
of Chinese writing, got his ideas from observing animals'
footprints and birds' claw marks on the sand as well as
other natural phenomena. He then started to work out
simple images from what he conceived as representing
different objects such as those that are given below:

Surely, the first images that the inventor drew of these few
objects could not have been quite so stylized but must have
undergone some modifications to reach the above stage.
Each image is composed of a minimum number of lines
and yet is easily recognizable. Nouns no doubt came first.
Later, new ideographs had to be invented to record actions,
feelings, and differences in size, colour, taste, and so forth.
Something was added to the already existing ideograph to
give it a new meaning. The ideograph for deer, for instance,

is , not a realistic image but a very much sim-

plified structure of lines suggesting a deer by its horns,
big eye, and small body, which distinguish it from other


animals. When two such simple images are

put side by side, the meaning is "pretty," "prettiness,"
"beautiful," "beauty," etc., which is obvious if one has
seen two such elegant creatures walking together. But,
if a third image is added above the other two, as


, it means "rough," "coarse," and even

"haughty." This interesting point is the change in meaning
through the arrangement of the images. If the three stags
were not standing in an orderly manner, they could be-
come rough and aggressive to anyone approaching them.
From the aesthetic point of view, three such images could
not be arranged side by side within an imaginary square
without cramping one another, and in the end none would
look like a deer at all.

After the shell-and-bone script came writing on bronze
vessels, known as bronze script. In the early days of divina- Bronze
script
tion, when the kings of the Shang dynasty (18th–12th cen-
tury BC) tried to solve their problems by consulting their
ancestors and deities, the latter's answers were engraved
on bones and on tortoise shells for perpetual preservation.
Later, bronze was used to make cooking utensils and wine
vessels for the special ceremonies of ancestral worship, raw
or cooked food being offered up in them. So sacred were

these ancestor-worshipping ceremonies that the best types of bronze utensil were specially designed and cast for such purposes, and, in addition, inscriptions, from a few words up to several hundred, were incised inside the bronzes. The words of the engravings could not be roughly formed or even just simple images; they had to be well worked out to go with the decorative ornaments outside the bronzes, and in some instances they almost became the chief decorative design in themselves. Though they preserved the general structure of the bone-and-shell script, they were considerably elaborated and beautified. Each bronze or set of them may bear a different type of inscription, not only in the wording but also in the manner of writing. Hundreds of them were created by different artists. The bronze script represents another stage of development in Chinese calligraphy, known as *chin-wen* ("metal-script"), *ku-wen* ("ancient-script"), or *ta chuan* ("large-seal") style of writing.

Before long a unification of all types of the bronze script was enforced when China was united for the first time, in the 3rd century BC. The first emperor of Ch'in, Shih Huang-ti, gave the task of working out the new script to his prime minister, Li Ssu, and no other type was allowed to be used. Here are some common words that can be compared with similar words in bone-and-shell script mentioned above:

sun moon mountain water rain wood dog cattle horse

This was the third step forward in the development of Chinese calligraphy, known as *hsiao chuan* ("small-seal") style.

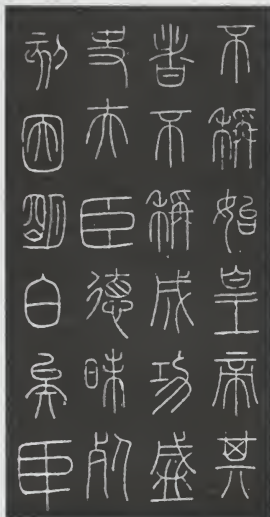
In the small-seal style of writing, all lines are drawn of even thickness, and more curves and circles are employed. Each word tends to fill up an imaginary square, and a passage written in small-seal style has the appearance of a series of equal squares neatly arranged in columns and rows, each of them balanced and well-spaced.

The hsiao chuan, or small-seal style

The uniformity of writing in China was established chiefly for the purpose of meeting the growing demands for documented records. Unfortunately, the small-seal style could not be written speedily and was therefore not entirely suitable. Another stage of development was needed—the fourth stage, which is called *li shu*, or official style. The Chinese word *li* here means "a petty official" or "a clerk"; *li shu* means a style specially devised for the use of clerks. If examined carefully, *li shu* is found to contain no circles and very few curved lines. Squares and short straight lines, vertical and horizontal, are chiefly used. Because of the speed needed for writing, the brush in the hand tends to move up and down, and an even thickness of line cannot be enforced. As the thickness varied, artist-writers could concentrate more on the artistic shaping of the lines.

Li shu is thought to have been invented by Ch'eng Miao (240–207 BC), who had offended the First Emperor of Ch'in and was serving a 10-year sentence in prison. He spent his time in prison working out this new development, which opened up seemingly endless possibilities for later calligraphers. According to their own artistic insight, they evolved new variations in the shape of lines and in construction. The words in *li shu* style tend to be square or slightly rectangular horizontally. Though the even thickness of lines is relaxed, the rigidity in the shaping of them is still there; for instance, the vertical lines had to be shorter, and the horizontal ones longer. As this curtailed the freedom of hand for individual artistic taste, another stage of development came into being—the fifth stage, *chen shu* (*k'ai shu*), or regular style. There is no record of who invented this style, but it must have been in evolution for a long time, at least since the 1st century AD if not earlier. The Chinese still use this regular style of writing today; in fact, what is known as modern Chinese writing is almost 2,000 years old, and the written words of China have not changed since the first century of the Christian Era.

Development of the chen shu, or regular style

"Regular style" means "the proper style of Chinese writing" used by all Chinese for government documents,


Hsiao chuan ("small-seal" style). Rubbing of a copy of Li Ssu's writing engraved on a stone epitaph, Ch'in dynasty (221–206 BC).

printed books, and public and private dealings in important matters ever since its establishment. Since the regulations for the civil service examination enforced in the T'ang period (AD 618–907), each candidate had to be able to write a good hand in regular style. This Imperial decree deeply influenced all Chinese who wanted to become scholars and enter the civil service. This examination was abolished in 1905, but most Chinese still try to acquire a hand in regular style even to the present day.

In *chen shu* each line, each square or angle, and even each dot can be shaped according to the will and taste of the calligrapher. Indeed, a Chinese word in regular style presents an almost infinite variety of problems of structure and composition, and, when executed, it presents to

the onlooker a design whose abstract beauty can draw the mind away from the literal meaning of the word itself.

The greatest exponents of Chinese calligraphy were Wang Hsi-chih (died 379) and his son Wang Hsien-chih in the 4th century. Few of their original works have survived, but a number of their writings were engraved on stone tablets, and rubbings were made from them. Many great calligraphers imitated their styles, but none ever surpassed them.

Wang Hsi-chih not only provided the greatest example in the regular style of writing but also relaxed the tension somewhat in the arrangement of the strokes in the regular style by giving easy movement to the brush to trail from one word to another. This is called *hsing shu*, or running style, as if the hand were walking fast while writing. This, in turn, led to the creation of *ts'ao shu*, or grass style, which takes its name from its appearance—as if the wind had blown over the grass in a manner disorderly yet orderly. The English term cursive writing cannot describe the Chinese grass style, for even a cursive hand can be deciphered without very much difficulty. But Chinese words in grass style are greatly simplified forms of the regular style and can be deciphered only by those who have practiced calligraphy for years. It is not a style for general use but for the calligrapher who wishes to produce a work of abstract art.

Technically speaking, there is no mystery in Chinese calligraphy. The tools for Chinese calligraphy are very few—good ink, ink stone, a good brush, and good paper (some prefer silk). It depends on the skill and imagination of the writer to give interesting shapes to his strokes and to compose beautiful structures from them without any retouching or shading and, most important of all, with well-balanced spaces between the strokes. This balance needs years of practice and training.

The fundamental inspiration of Chinese calligraphy, as of all arts in China, is nature. In regular style each stroke, even each dot, suggests the form of a natural object. As every twig of a living tree is alive, so every tiny stroke of a piece of fine calligraphy has the energy of a living thing. Printing does not admit the slightest variation in the shapes and structures, but strict regularity is not tolerated by Chinese calligraphers, especially those who are masters of the *ts'ao shu.* A finished piece of fine calligraphy is not a symmetrical arrangement of conventional shape but, rather, something like the coordinated movements of a skillfully composed dance—impulse, momentum, momentary poise, and the interplay of active forces combining to form a balanced whole.   (C.Y./Ed.)

Korean calligraphy. Koreans have used Chinese characters probably since the 2nd or 3rd century AD. Even after the invention of the Korean alphabet in 1447, Chinese was used as the official script until the 19th century.

A few inscribed stone monuments remain from the Three Kingdoms period (*c.* 57 BC–AD 668). Ancient Koreans, eager to adopt Chinese culture, developed a calligraphy reflecting Chinese styles. In the following Unified Silla dynasty (668–935), a devotion and adherence to the T'ang culture of China gave birth to such great masters of calligraphy in Korea as Kim Saing and Choi Ch'i-wŏn, whose styles of writing basically followed those of the Chinese calligraphers Ou-yang Hsün and Yü Shih-nan.

The angular, squarish style of Ou-yang Hsün, Yü Shih-nan, and Yen Chen-ch'ing, inherited from the Silla dynasty, continued in the Koryŏ period (918–1392) until around 1350, when the rounded, fluent style of the Chinese calligrapher Chao Meng-fu, of the Yüan dynasty, was introduced and became the vogue. Since that time the *chao* style has remained the basic undercurrent in Korean calligraphy.

The *chao* style

At first the calligraphy of the Yi dynasty (1392–1910) followed the *chao* style, but early in the 16th century a mannered, vulgar style began to be evident. The 19th century saw, however, the emergence of individual styles related to those of Chinese calligraphers. The new trend was the result of Korea's close cultural contacts with Ch'ing China.

The greatest master of the Yi period was Kim Chŏng Hi, who established the so-called *ch'usa* style. His calligraphy is derived from the *li shu* script of China, but his sense of pictorial composition, harmony within asymmetry, and animation by unmatched, forceful strokes gave him a style completely his own.

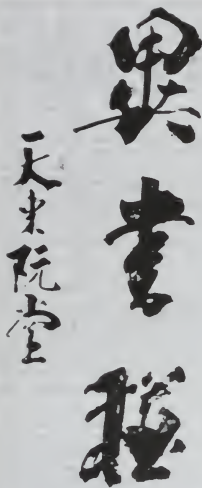
The influence of Japanese calligraphy began to be felt about 1920. Since World War II, calligraphy in both North and South Korea has been profoundly influenced by governmental decisions to replace all Chinese characters with words written in the native alphabet. As a consequence, modern Korean calligraphy has been developing along new lines.   (W.-Y.K./Ed.)

Japanese calligraphy. The art of calligraphy has long been highly esteemed in Japan as in China. There is no definite record of when the Japanese began to use Chinese words—called *kanji* in Japanese. It is known that a Korean scribe named Wani brought some Chinese books of Confucian classics, such as the *Analects, Great Learning,* and *Book of Mencius,* to Japan near the end of the 4th century AD. From the 7th century onward, many Japanese scholars, particularly Buddhist monks, went to China, and some Chinese went to Japan. As Indian Buddhism reached Japan via Korea and China and took root there, the use of *kanji* in Japan gradually grew. Eventually, *kanji* became the official system of writing in Japan.

Kanji script

Most of the Chinese Buddhist monks who went to live in Japan were scholars and good calligraphers; their writings on the Buddhist scriptures and other subjects were admired and esteemed not only for their aesthetic value as calligraphy but also because they induced a sense of religious awe in the readers.

Many of the early Japanese emperors were ardent Buddhists and also acquired a masterly hand in *kanji* writings. So did many Japanese Zen priests, whose calligraphy tended to exercise a religious effect upon the Japanese mind. Theirs became a special type of calligraphy in Japan, namely, Japanese Zen calligraphy, or *bokuseki.*

Naturally, it was unsuitable for Japan to adopt an entire foreign language like Chinese, and Japanese thinkers


Ch'usa style written by Kim Chong Hi (1786–1856), Yi period.

Hiragana calligraphy

began to devise a new, native script known as *hiragana*, which was often referred to as "women's hand," or *onnade* in Japanese. It was used particularly in the writing of Japanese poetry and had an elegant and graceful appearance.

There are many outstanding pieces of Japanese calligraphy in *kanji*, but they are not distinctive when compared with their Chinese counterparts. Japanese *hiragana* calligraphy, however, stands out prominently and proudly, especially in the style of *remmen-tai*, in which the *hiragana* are written continuously and connected together without break, and in *chōwa-tai*, in which some *kanji* words join hands with the *hiragana*. Japanese calligraphy in *remmen-tai* or in *chōwa-tai* has some resemblance to the Chinese grass style, but the two are easily distinguishable. In Chinese grass style, although the words are greatly simplified and several words can be joined together with trailing strokes, each separate word normally still retains its regular spacing within an imaginary square, big or small. But Japanese *hiragana* cannot be spaced so separately and evenly. Therefore, a whole piece of *remmen-tai* calligraphy looks like a big bundle of beautiful silk strings hanging down confusedly yet artistically, as if the calligrapher had let his hand move swiftly of its own accord. The separate strokes and dots have no distinctive shape but join other strokes and dots in the following *hiragana*. The strokes or lines in *hiragana* are not shaped like living things, nor are they of even thickness; but there must be good spacing between the strokes or lines and between one *hiragana* and another, so that there is no confusion or blur in the completed piece. This is a highly demanding art, and the whole piece has to be executed with speed and without hesitation. *Hiragana* requires solid training and artistic insight.   (C.Y./Ed.)

BIBLIOGRAPHY

General studies: GEOFFREY SAMPSON, *Writing Systems: A Linguistic Introduction* (1985), is the first systematic account of the relations between various writing systems and the linguistic structures they represent, with an especially good section on Chinese, Japanese, and Korean. ROY HARRIS, *The Origin of Writing* (1986); ALBERTINE GAUR, *A History of Writing* (1984); IGNACE J. GELB, *A Study of Writing*, rev. ed. (1963, reprinted 1969); DAVID DIRINGER, *The Alphabet: A Key to the History of Mankind*, 3rd ed. rev., 2 vol. (1968); and HANS JENSEN, *Sign, Symbol, and Script: An Account of Man's Efforts to Write*, 3rd rev. and enl. ed. (1968; originally published in German, 1935), are standard introductions to writing and the alphabet. ERIC A. HAVELOCK, *The Literate Revolution in Greece and Its Cultural Consequences* (1982); and JACK GOODY (ed.), *Literacy in Traditional Societies* (1968, reprinted 1975), examine the cultural, historical, and psychological dimensions of alphabetic writing systems. See also HARVEY J. GRAFF (ed.), *Literacy and Social Development in the West: A Reader* (1981). JACQUES DERRIDA, *Of Grammatology* (1976; originally published in French, 1967), examines the conceptual implications of writing. BRIAN STOCK, *The Implications of Literacy: Written Language and Models of Interpretation in the Eleventh and Twelfth Centuries* (1983), sets out the increasing uses of writing in the Middle Ages that presaged the Reformation. Good introductions to writing and its uses are provided by ROBERT PATTISON, *On Literacy: The Politics of the Word from Homer to the Age of Rock* (1982); DONALD JACKSON, *The Story of Writing* (1981); and MARCEL COHEN, *La Grande Invention de l'écriture et son évolution*, 2 vol. (1958). INSUP TAYLOR and M. MARTIN TAYLOR, *The Psychology of Reading* (1983), discusses the relation between various writing systems and the psychological processes involved in learning to read and write them. DAVID R. OLSON, NANCY TORRANCE, and ANGELA HILDYARD (eds.), *Literacy, Language, and Learning: The Nature and Consequences of Reading and Writing* (1985), gives a sampling of the interdisciplinary nature of recent work on literacy. Hieroglyphs: Books in English on hieroglyphic writing include ALAN H. GARDINER, *Egyptian Grammar*, 3rd ed., rev. (1957, reprinted 1978), with a list of hieroglyphs from the Middle Kingdom; F.LL. GRIFFITH, *A Collection of Hieroglyphs: A Contribution to the History of Egyptian Writing* (1898); and NINA M. DAVIES, *Picture Writing in Ancient Egypt* (1958), a collection of artistically valuable hieroglyphs.

Punctuation: G.V. CAREY, *Mind the Stop,* rev. ed. (1958, reissued 1976); and E.H. PARTRIDGE, *You Have a Point There: A Guide to Punctuation and Its Allies* (1953, reissued 1978), are the best guides to modern punctuation as practiced in Britain; the latter is more exhaustive and includes a chapter on American practice by JOHN W. CLARK. A comparable American work is the chapter on punctuation in WILMA R. EBBITT and DAVID R. EBBITT, *Writer's Guide and Index to English,* 6th ed. (1978). The following describe the practices of two famous presses, Oxford University Press and the University of Chicago Press: HORACE HART, *Hart's Rules for Compositors and Readers at the University Press, Oxford,* 39th ed. rev. (1983); and *A Manual of Style: For Authors, Editors and Copywriters,* 13th ed. rev. (1982). For punctuation in antiquity and the Middle Ages, see FRANZ STEFFENS, *Lateinische Paläographie,* 2nd ed. (1907, reissued 1964); and PETER CLEMOES, *Liturgical Influence on Punctuation in Late Old English and Early Middle English Manuscripts* (1952). For punctuation in and since the Renaissance, especially in Britain, see the relevant sections in A.C. PARTRIDGE, *Orthography in Shakespeare and Elizabethan Drama: A Study of Colloquial Contractions, Elision, Prosody, and Punctuation* (1964); and T.F. HUSBAND and M.F.A. HUSBAND, *Punctuation: Its Principles and Practice* (1905). ALEXANDER BIELING, *Das Princip der deutschen Interpunktion: Nebst einer übersichtlichen Darstellung ihrer Geschichte* (1880), is useful for German and for European punctuation in general since the 15th century.

Shorthand: EDWARD HARRY BUTLER, *The Story of British Shorthand* (1951), a complete history of early shorthand systems with emphasis on modern British systems; HANS GLATTE, *Shorthand Systems of the World: A Concise Historical and Technical Review* (1959), a short history that emphasizes the extent to which important systems spread to countries other than those in which they originated; LOUIS A. LESLIE (ed.), *The Story of Gregg Shorthand: Based on the Writings of John Robert Gregg* (1964), on the early life of John Robert Gregg, his invention of Gregg shorthand, his promotion of the system in the United States, and his method of teaching; ISAAC PITMAN, *A History of Shorthand,* 4th ed. (1918), a chronological history of shorthand systems with emphasis on British systems to the end of the 19th century; and ALLIEN R. RUSSON, *Methods of Teaching Shorthand* (1968), the history of shorthand instruction.

Aramaic and Hebrew calligraphy: G.R. DRIVER, *Semitic Writing from Pictograph to Alphabet,* rev. ed. edited by S.A. HOPKINS (1976), on the origins of Semitic writing; G.R. DRIVER (ed. and trans.), *Aramaic Documents of the Fifth Century B.C.* (1954, reprinted 1968); EUGÈNE TISSERANT (comp.), *Specimina Codicum Orientalium* (1914), reproductions of Semitic pen hands; CARLO BERNHEIMER, *Paleografia Ebraica* (1924), many Ashkenazic hands; MOSES GASTER, *Hebrew Illuminated Bibles of the IXth and Xth Centuries . . .* (1901); REUBEN LEAF, *Hebrew Alphabets, 400 B.C. to Our Days* (1950, reissued 1987), reproductions of manuscript styles; *The Book of Jonah,* woodcuts by JACOB STEINHARDT, calligraphy by FRANZISCA BARUCH (1953); and HENRI FRIEDLAENDER, *Die Entstehung meiner Hadassah-Hebräisch* (1967), on the relationship of Hebrew manuscript styles and types.

Arabic calligraphy: ANNEMARIE SCHIMMEL, *Islamic Calligraphy* (1970), a stimulating introduction with illustrations, including calligraphy in architecture and the decorative arts, and a useful bibliography, and *Calligraphy and Islamic Culture* (1984); YASIN HAMID SAFADI, *Islamic Calligraphy* (1978), on the development of Arabic writing from pre-Islāmic times through the 20th century; NABIA ABBOTT, *The Rise of the North Arabic Script and Its Kur'ānic Development* (1939), a study of the origins of the Arabic script and its development in the early Islāmic period; B. MORITZ (ed.), *Arabic Palaeography: A Collection of Arabic Texts from the First Century of the Hidjra till the Year 1000* (1905, reprinted 1986), a rich collection of texts on papyrus and paper; ANTHONY WELCH, *Calligraphy in the Arts of the Muslim World* (1979), essays on aspects of calligraphy in Islām; ARTHUR UPHAM POPE (ed.), *A Survey of Persian Art,* new ed. (1964), especially vol. 4 on Arabic calligraphy in the art and architecture of Persia; BASIL GRAY (ed.), *The Arts of the Book in Central Asia, 14th–16th Centuries* (1979), a work unique in both coverage and scholarship; and V. MINORSKY (trans.), *Calligraphers and Painters: A Treatise by Qāḍī Aḥmad . . .* (1959), an important work (written in 1606) that illustrates the Islāmic attitude toward calligraphy.

Western calligraphy: DOROTHY E. MINER, VICTOR I. CARLSON, and P.W. FILBY (comps.), *2,000 Years of Calligraphy* (1965, reissued 1980), a comprehensive and well-illustrated catalog of an exhibition devoted to regions using the Latin alphabet, with especially valuable notes and references from the 1st to the 19th century; EDWARD JOHNSTON, *Writing & Illuminating, & Lettering,* 14th ed. (1906, reprinted 1980), the gospel of the modern revival by its chief apostle, and *Formal Penmanship, and Other Papers,* edited by HEATHER CHILD (1971, reissued 1980); DAVID DIRINGER, *The Hand-Produced Book* (1953, reprinted with ti-

tle, *The Book Before Printing: Ancient, Medieval, and Oriental,* 1982), a storehouse of information; JAN TSCHICHOLD, *An Illustrated History of Writing and Lettering* (1946, reissued 1948; originally published in German, 1940), a brief, perceptive, and personal account by an eminent designer; HERMANN DEGERING (ed.), *Lettering: A Series of 240 Plates Illustrating Modes of Writing in Western Europe from Antiquity to the End of the 18th Century,* 3rd ed. (1954, reprinted 1965; originally published in German, 3rd ed. 1952), a standard survey of scripts; and B.L. ULLMAN, *The Origin and Development of Humanistic Script* (1960, reprinted 1974). See also JOYCE IRENE WHALLEY, *The Pen's Excellencie: Calligraphy of Western Europe and America* (1980, reprinted 1982); MARC DROGIN, *Medieval Calligraphy, Its History and Technique* (1980); JAMES WARDROP, *The Script of Humanism: Some Aspects of Humanistic Script, 1460–1560* (1963); ALFRED FAIRBANK and BERTHOLD WOLPE, *Renaissance Handwriting: An Anthology of Italic Scripts* (1960); OSCAR OGG (ed.), *Three Classics of Italian Calligraphy: An Unabridged Reissue of the Writing Books of Arrighi, Tagliente, Palatino* (1953); AMBROSE HEAL, *The English Writing-Masters and Their Copy-Books, 1570–1800* (1931, reprinted 1962), the fundamental biographical and bibliographical work, well illustrated and with an important essay by STANLEY MORISON; RAY NASH, *American Writing Masters and Copybooks: History and Bibliography Through Colonial Times* (1959), and *American Penmanship, 1800–1850: A History of Writing and a Bibliography of Copybooks from Jenkins to Spencer* (1969), with miniature reproductions of title pages.

Greek calligraphy: E.G. TURNER, *Greek Manuscripts of the Ancient World,* 2nd ed. (1987), the best general work and also very well illustrated; BRUCE M. METZGER, *Manuscripts of the Greek Bible: An Introduction to Greek Palaeography* (1981); FRANCHI DE'CAVALIERI and JOHANNES LIETZMANN, *Specimina Codicum Graecorum Vaticanorum* (1910, reissued 1929), 50 Greek manuscript specimens in the Biblioteca Apostolica Vaticana, Vatican City; *The Codex Alexandrinus,* 5 vol. (1909–57), a facsimile in reduced size, with introductions by F.G. KENYON, H.J.M. MILNE, and T.C. SKEAT; *The Codex Sinaiticus and the Codex Alexandrinus,* prepared by H.J.M. MILNE and T.C. SKEAT (1951, reissued 1963), on the origins of the two great Greek uncial Bibles in the British Museum; *Facsimile of the Washington Manuscript of Deuteronomy and Joshua in the Freer Collection* (1910); and *Ilias Ambrosiana* (1953), a beautiful facsimile of the Homeric codex in the Biblioteca Ambrosiana, Milan (elegant uncial writing).

Latin calligraphy: The best short accounts in English are in B.L. ULLMAN, *Ancient Writing and Its Influence,* new ed. (1969, reprinted 1980); and EDWARD MAUNDE THOMPSON, *An Introduction to Greek and Latin Palaeography* (1912, reprinted 1973). All Roman books and documents are cataloged (in English) in, respectively, E.A. LOWE (ed.), *Codices latini antiquiores: A Palaeographical Guide to Latin Manuscripts Prior to the Ninth Century,* 12 vol. (1934–66, reprinted 1982); and ALBERT BRUCKNER and ROBERT MARICHAL (eds.), *Chartae latinae antiquiores: Facsimile Edition of the Latin Charters Prior to the Ninth Century* (1954–   ), 24 vol. of which had appeared to 1986. The most important monographs are JEAN MALLON, *Paléographie romaine* (1952); and essays in E.A. LOWE, *Palaeographical Papers 1907–1965,* 2 vol. (1972). LEONARD E. BOYLE, *Medieval Latin Palaeography: A Bibliographical Introduction* (1984), is a guide to further study of Latin scripts.

Chinese calligraphy: YU-HO ECKE TSENG, *Chinese Calligraphy* (1971); SHEN FU, *Traces of the Brush: Studies in Chinese Calligraphy* (1977, reissued 1980); LUCY DRISCOLL and KENJI TODA, *Chinese Calligraphy,* 2nd ed. (1964); YEE CHIANG, *Chinese Calligraphy: An Introduction to Its Aesthetic and Techniques,* 3rd ed. rev. and enl. (1973); WILLIAM WILLETTS, *Chinese Calligraphy: Its History and Aesthetic Motivation* (1981), and *Chinese Art,* 2 vol. in 1 (1958); CHIH-MAI CH'ÊN, *Chinese Calligraphers and Their Art* (1966); and SHEN FU, GLENN D. LOWRY, and ANN YONEMURA, *From Concept to Context: Approaches to Asian and Chinese Calligraphy* (1986).

Korean calligraphy: EUNG-HYON KIM, "Sang-ko eui Sŏye" (Ancient Korean Calligraphy), "Koryŏ eui Sŏye" (Calligraphy of the Koryŏ Dynasty), "Yi-cho eui Sŏye" (Calligraphy of the Yi Dynasty), and "Hyondae eui Soye" (Modern Calligraphy), all in *Han'guk yesul ch'ongnam,* edited by the Academy of Art, Seoul, Korea (1965), the best surveys on Korean calligraphy, by a noted calligrapher; and KI-SUNG KIM, *Han'guk Sŏye sa* (1966), a general survey of Korean calligraphy.

Japanese calligraphy: YOSHIAKI SHIMIZU and JOHN M. ROSENFIELD, *Masters of Japanese Calligraphy 8th–19th Century* (1984); YUJIRO NAKATA, *The Art of Japanese Calligraphy* (1973; originally published in Japanese, 1967); and HISAO SUGAHARA, *Japanese Ink Painting and Calligraphy . . . ,* trans. from Japanese (1967).

Yiddish Literature

Yiddish literature may be said to have been born twice. The earliest evidence of Yiddish literary activity dates from the 13th century and is found in southern Germany, where the language itself had originated as a specifically Jewish variant of Middle High German approximately a quarter of a millennium earlier. The Haskalah, the Jewish equivalent of the Enlightenment, effectively doomed the Yiddish language and its literary culture in Germany and in western Europe during the course of the 18th century. At the beginning of the 19th century, however, the Haskalah paradoxically promoted a renascence of Yiddish literature in those parts of eastern Europe to which the Yiddish language had been carried from the 13th century onward. The Haskalah therefore represents a watershed separating two essentially distinct cultural phenomena. Whereas in eastern Europe in the 19th and 20th centuries Yiddish literature eventually became an autonomous modern mode of literary expression fully comparable with parallel European literatures, the Yiddish literature of medieval Germany and the adjacent territories to which it spread remained in the shadow of the infinitely more prestigious Hebrew literature and, in theory at least, was addressed only to women (who were not taught Hebrew but learned to read and write Yiddish in the community schools) and to untutored men.

The low regard in which the Yiddish language and its culture were held conspired with the ravages of time and the turbulent vicissitudes of Jewish history in the German-speaking lands in such a way that all but a small proportion of medieval Yiddish texts have been lost, though important texts are still coming to light. From what survives, however, it is clear that the literature aimed predominantly at the edification of its readership and was either didactic in character or sought to entertain while serving as an antidote to the supposed moral dangers of Gentile literature. As a result of their traditional respect for learning, the efficacy of their community schools, and their predominantly urban way of life, literacy was much higher among the Jews of northern Europe during this time than among non-Jews living in the same area. Many works achieved such popularity that they were frequently reprinted over a period of centuries and enjoyed an astonishingly wide dissemination, with the result that their language developed into an increasingly ossified koine that was readily understood over a territory extending from Amsterdam to Odessa and from Venice to Hamburg. During the 18th century the picture changed rapidly in western Europe, where increasing cultural assimilation led to the abandonment of Yiddish in favour of the languages of the ambient societies. In eastern Europe, on the other hand, the Haskalah, as a result of the recognition that its mission to enlighten the Jewish masses could only be accomplished through the medium of Yiddish, unintentionally wrought a renewal of the language it disparaged. The resurgence of Yiddish literature in eastern Europe went hand in hand with the emergence of a new standard literary language based on the eastern dialects, which had been invigorated by contact with the languages of its Slavic environment.

This article provides a historical survey of the development of Yiddish literature. For a discussion of literature in Hebrew, see the article HEBREW LITERATURE.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, section 621.

The article is divided into the following sections:

The Middle Ages to the 18th century in western Europe

BIBLICAL AND RELIGIOUS LITERATURE

The earliest recorded sentence written in Yiddish is a blessing inscribed in a mahzor (prayer book for the Jewish holidays) written in Worms in 1272–73. Other rudimentary signs of Yiddish literary activity from the 13th century, or perhaps earlier, are interlinear and marginal glosses found in manuscripts of books of the Bible and of biblical commentaries. Glossaries were made from the end of the 14th century onward. The earliest known printed Yiddish book is a Hebrew–Yiddish glossary and concordance of the Hebrew Bible published in Kraków in 1534 and known as the *Seyfer shel Reb Anshel* ("Book of Rabbi Anshel"). The oldest known printed Yiddish text is a version of the Passover hymn *Addir Hu* ("Mighty is He"), which appears as *Almekhtiger Got* in a Haggadah (a book of Jewish lore) published in Prague in 1526. Actual translations of portions of the Bible appear from the end of the 15th century onward. The earliest example to which a definite date may be assigned is a 1490 Yiddish manuscript version of the Psalms. Printed Yiddish Pentateuchs (the first five books of the Old Testament) were first published in Constance and Augsburg in 1544, while a *Taytsh khumesh*—a Pentateuch accompanied by the appointed portions of The Prophets (Hebrew: Nevi'im) and the five Scrolls (Megiles; Hebrew: Megillot), together with extracts from the celebrated 11th-century commentator Rashi—appeared in Cremona in 1560.

Considerable popularity was also attained by rhymed adaptations of parts or the whole of the Bible, many of which were embroidered with material from midrashim (anthologies of rabbinic sayings, parables, and tales arranged as expositions of books of the Bible, chapter by chapter). The earliest extant example is a manuscript dated 1382 that was found in Cairo at the end of the 19th century. It is housed in the Cambridge University Library and is known as the Cambridge Yiddish Codex. It includes the stories of Aaron, the Garden of Eden, the young Abraham, and of Joseph and Potiphar.

Greater originality was evinced by the biblical epics that survive from the 16th century, some of which may have been written earlier. Jewish audiences had long been familiar with more or less lightly expurgated German sagas and romances. The Cambridge Yiddish Codex includes a Hebrew-alphabet version of a section of the Gudrun cycle that is approximately 130 years older than the earliest recorded Middle High German version. There are also Hebrew-alphabet manuscript versions of the chivalric romance *Wigalois,* and evidence suggests that there were once Jewish versions of a number of other Middle High German epics.

Though perhaps these Hebrew-alphabet versions of German material should not strictly speaking be accounted a part of Yiddish literature, they certainly served as models for more authentically Jewish biblical epics. By far the most notable of these is the *Shmuel-bukh* ("Samuel Book"), published in Augsburg in 1544. Its anonymous author rendered the story of the prophet Samuel, of King

Earliest printed Yiddish works

Biblical epics

Saul, and above all of King David into the rhymed stanzas of the *Nibelungenlied.* Using material from what at that time was still a single Book of Samuel copiously embellished with legends drawn from the Talmud and from midrashic sources, the author fashioned a dramatic panorama filled with realistically depicted battle scenes and heroic deeds narrated with an element of suspense, together with much broad humour and erotic incident, all centred on the somewhat idealized image of King David. A similar but slightly less successful treatment of the Books of Kings was the *Melokhim-bukh,* published in 1543.

Of all the various forms of Yiddish biblical literature the most popular was the *Tsenerene,* a paraphrase of the Pentateuch with other appointed portions of Scripture enriched with midrashic material. It was written at the end of the 16th century by Jacob ben Isaac Ashkenazi of Janów Lubelski. The work appears to have been published in Lublin some time between 1590 and 1600; it has gone through more than 200 editions and has remained constantly in print. The *Seyfer ha-maged* was almost as popular and took the form of a sequel to the *Tsenerene,* encompassing the Prophets and the Hagiographa in the original Hebrew text together with a paraphrase and Rashi's commentary in Yiddish.

Though the 16th century had seen numerous rhymed and more or less freely adapted versions of parts of the Bible, it was not until 1676–79 that Yekusyel ben Yitskhek Blits produced a translation of the Hebrew Scriptures in Amsterdam. By then there had been a reaction against the type of embroidered homiletic version used in the *Tsenerene,* and, in emulation of Martin Luther, an attempt was made to produce a translation close to the original that, nonetheless, eschewed word-for-word glossing. This approach was even more pronounced in the case of the second complete Yiddish Bible, which was translated by Yoysef Vitsnhoyzn and published in Amsterdam in 1679.

Freely adapted biblical material eventually found its way into drama around the end of the 17th century. Jewish tradition did not originally permit theatrical performances, and only at the time of the feast of Purim was this prohibition relaxed sufficiently to allow extempore enactment of the Megile of Esther, associated with the feast, and subsequently of other biblical stories. The oldest extant manuscript of such a Purim play (Purim-shpiln) is *Akhashveresh-shpil,* named after the Persian king, Ahasuerus, in the Book of Esther. Other subjects of the early Purim plays that have survived are the story of the sale of Joseph into captivity and the story of David and Goliath.

margin: Purim plays

Collections of prayers either with a Yiddish translation at the foot of the Hebrew text or in Yiddish only, whether for daily use or specially for the holidays, are found from the 16th century onward. The first printed Yiddish prayer book dates from 1544. More interesting, however, are the *tkhines,* which are collections of prayers for the use of women. Whereas the prayers for general use invoke the deity in the name of the community and closely follow the liturgical canon, the *tkhines* articulate the personal supplications of individual women and communicate far more about the joys and particularly the sorrows of everyday Jewish life in 16th-century Germany. This is also the case with the *minhagim,* or custom books, which recorded prevalent ritual usages as they had developed in particular communities. The *minhagim,* together with *musar* books, which prescribe norms of moral conduct, reflect prevailing ideals concerning everyday life. The earliest *musar* books in Yiddish were translations from Hebrew, but at the beginning of the 17th century a number were composed in Yiddish. Among these the *Seyfer brantshpigl* (1602; "The Burning Mirror") by Moyshe Khanekh Altshul was preeminent.

SECULAR LITERATURE

A genre that occupies an intermediate position between religious and secular writings is represented by collections of stories and fables, in which free adaptations of midrashic and talmudic material are found side by side with tales garnered from a variety of Gentile sources. The most notable example is *Eyn sheyn mayse-bukh* ("A Beautiful Story Book"), usually referred to simply as the *Mayse-*

bukh, published in Basel in 1602 by Yankev ben Avrom of Międzyrzecz. Many of the stories are designed to illustrate an edifying moral or to provide models of behaviour.

By far the most accomplished Yiddish writer of this period was Elye ben Asher ha-Levi, known as Elijah Levita or Elye Bokher. Though he was born near Nürnberg, he lived and worked primarily in Padua, Venice, and Rome. He was a noted Hebrew grammarian, and his Yiddish translation of the Psalms, published in Venice in 1545, was the first to be printed and achieved great popularity. He also wrote the verse lampoons *Sreyfe fun Venetsye* ("The Fire of Venice") and *ha-Mavdil* ("Benediction"), but he made his reputation chiefly as the author of the Yiddish romances, the *Bove-bukh* and *Pariz un Viene.* The *Bove-bukh,* or *Bove d'Antona* as it was entitled in its first edition (1541), was composed in 1507–08 and takes the form of an abridged and skillful adaptation of one of the many Italian versions of the *Buève de Hantone,* an Anglo-Norman *chanson de geste.* The molding of the story to Jewish taste and the virtuoso performance in adapting the Italian *ottava rima* stanza to the Yiddish language (at much the same time and place as Giuseppe Sarfati was introducing this form into Hebrew poetry) are both evidence of exceptional literary talent. His *Pariz un Viene,* based on the Italian version of an originally Provençal source, was an even greater tour de force but does not seem to have achieved the same popularity and survives in only two incomplete copies printed in Verona in 1594.

margin: Yiddish adaptation of the romance

The troubled social conditions in which the Jews of Germany lived during the 17th and 18th centuries are reflected in a class of verse narratives that served to disseminate news of blood-libels, expulsions, and pogroms. The narratives are similar to the rhymed chronicles or *historische Volkslieder* ("historical folk songs") that circulated as broadsheets and pamphlets in Germany at the same time. Indeed, the Yiddish songs often constituted rebuttals of the anti-Semitic libels in the German *Lieder.* The earliest and best known example is the *Sheyn lid megiles Vints,* by Elkhonen ben Avrom Heln, which tells of anti-Semitic rioting during a popular uprising led by Vincenz Fettmilch against the patrician oligarchy of Frankfurt am Main in 1612–14. The earliest extant copy is that printed in Amsterdam in 1648. Other examples are a *Meshiakh-lid* (1666; "Messiah Song"), about the false Messiah, Shabse Tsvi (Sabbatai Ẓevi); and a *Shvedish lid* ("Swedish Song"), concerning events in the Swedish War in 1648, at a time when Jewish refugees were fleeing into Germany as a result of the Khmelnitsky massacres in the Ukraine.

The most vivid reflection of Jewish everyday life in 17th- and early 18th-century Germany is found in the *Zikhroynes mores Glikl Hamil* (1896; *The Life of Glückel of Hameln*). These memoirs, written during the years 1691 to 1719, were not intended for publication but represented a kind of spiritual legacy to Glikl's 14 widely scattered children. The subjects on which she touches are extremely varied and highly informative concerning the social, cultural, and economic circumstances of the German Jews of her time. She tells of wars and plagues, of wedding feasts and bankruptcies, and of the impact on Germany of the hysteria aroused by Shabse Tsvi.

Yiddish literature in Germany and the West came to a virtual end with a handful of didactic comedies written by followers of Moses Mendelssohn and members of the Haskalah, who in principle were proponents of the repudiation of Yiddish in favour of standard German. Typical of this tendency was Arn Volfzon-Hale's *Laykhtzin un fremeley* (1796; "Frivolity and Bigotry"). It is subtitled a *Familyen-gemelde,* or "Family Portrait," and bears comparison with the bourgeois drama that had become fashionable on the contemporary German stage. The intention was to provide a modern secular alternative to the traditional Purim play, and this was certainly the first time that aspects of contemporary life had made an appearance in Yiddish drama.

margin: Yiddish literature's demise in western Europe

Western Yiddish survived into the 19th century, and in certain areas immediately outside of the frontiers of Germany the language was still alive after World War II. No further literature of any significance was produced, however, in western Europe.

Modern literature in eastern Europe and in emigration

THE 19TH CENTURY

A resurgence of Yiddish literature in eastern Europe overlapped chronologically with the decline in the West. To a large extent it was shaped by the struggle between the Haskalah and Hasidism. The Hasidic religious revival, which originated in Podolia in the 18th century, sought communion with nature and spontaneity of worship in song and dance. The emphasis placed on individual fervour naturally favoured the free expression of feeling in Yiddish in contrast to formulaic liturgy in Hebrew. The main literary reflections of this ethos were the eulogies of the movement's founder, Israel ben Eliezer (known as the Ba'al Shem Tov); and above all the mystical tales of his great-grandson, Reb Nakhmen (Rabbi Nahman) of Bratslav.

The *maskilim,* adherents of the Haskalah, considered such Hasidic literature inimical to the enlightenment of the Jewish people and set about combating its influence by means of parody and satire. In particular it was the aim of the Haskalah to expose the supposed hypocrisy of the Hasidic rabbis and to ridicule the obscurantism of their tales. The Yiddish author most widely read during this period was Ayzik Meyer Dik, whose anti-Hasidic tone was less pronounced than that of his contemporaries, Yisroel Aksenfeld and Shloyme Etinger. Dik produced more than 400 sentimental and historical novels, many of which have disappeared because the cheap unbound editions in which they were produced were quite literally read to shreds.

The more committed maskilic writers were confined to parody by the very fact of their ideological alienation from their mass audience and from the world they described. This had the somewhat paradoxical effect of concentrating their attention on the use of colloquial language in dramatic dialogue, a fact that played a significant role in the gradual molding of the new eastern European standard literary Yiddish. At the same time, however, this restriction of scope severely limited the dimensions of their narrative perspective. A crucial step in overcoming this limitation and in the development of Yiddish literature in general was taken in 1864 when Sholem Yankev Abramovitsh (also spelled Shalom Jacob Abramowitsch) published *Dos kleyne mentshele* ("The Little Man"). It appeared anonymously in 12 installments in *Kol mevaser* ("The Herald"), the first successful Yiddish weekly journal. At the beginning of *Dos kleyne mentshele* Abramovitsh introduced the reader to his narrator, Mendele Moykher Sforim ("Mendele the Itinerant Bookseller"). Mendele's name, also spelled Mendele Mokher Sefarim, came to be regarded as the author's pseudonym, but Mendele is more accurately thought of as a brilliantly conceived narrative voice that permits his creator subtle ironic shifts of perspective. In 1865 there followed the first version of *Dos vintshfingerl* ("The Magic Ring"), which after complex revision was eventually to become his major novel. A play, *Di takse* (1869; "The Tax"), treated economic and class antagonisms within Jewish society for the first time. Abramovitsh's satirical allegory, *Di klyatshe* (1873; *The Nag*), represents the fate of the Jewish nation in the form of a prince transformed into a broken, maltreated horse.

Yoyel Linetski benefited greatly from advances in narrative technique made by Abramovitsh. In *Dos poylishe yingl* (1869; *The Polish Boy*), which became immensely popular, Linetski adopted the device of the *faux-naif* narrator.

When Shloyme Etinger's tragicomedy *Serkele* was performed by students at the Zhitomir rabbinical academy in 1862 it was the first time that a modern Yiddish play actually had been enacted. In 1876, however, Avrom Goldfadn (Abraham Goldfaden) traveled to Romania, where he joined forces with a group of singers to mount open-air performances. At first these were limited to a scenario-framework for his songs. Music played an important role in Goldfadn's work and many of his compositions acquired almost the status of folk songs. In 1877 the company performed his first play, *Shmendrik.* The play itself was a sentimental comedy attacking the custom of enforcing arranged matches particularly in Hasidic families.

Its real significance lay, however, in the fact that it constituted the beginning of a professional Yiddish theatre, which was destined to play to packed houses in London, Buenos Aires, and New York City by the turn of the century, and which before it disappeared made a significant contribution to the Broadway and Hollywood industries. In response to the rising tide of anti-Semitism in the 1880s, Goldfadn's plays became more serious, more critical of superficial Haskalah rationalism, and increasingly nationalistic in tone. Though set in 14th-century Palermo, *Doktor Almosado,* which had its premiere performance in St. Petersburg in 1882, reflected the recent pogroms in Russia. Plays set in Palestine, such as *Bar Kokhba* (1883) or his final work, *Ben-Ami* (1907; "Son of My People"), were strongly Zionist in sympathy.

In the 1880s Yiddish literature as a whole saw a movement away from the militant educational campaign of the Haskalah and a corresponding tendency to espouse national values and to adopt a less ambivalent attitude toward Yiddish. This shift of emphasis was particularly evident in the works of Sholem Rabinovitsh, or Sholem Aleykhem (Sholem Aleichem), as he called his authorial persona from an early stage. With his arrival on the literary scene Yiddish literature made further strides toward self-conscious maturity. Having already shown early promise in a number of novels, stories, and feuilletons, he made a savage attack in *Shomers mishpet* (1888; "The Trial of Shomer") on the sentimental pulp fiction that in his view demeaned the status of Yiddish letters. Then in the two volumes of *Di yidishe folks-biblyotek* (1888–89; "The Yiddish Popular Anthology") he provided examples, drawn from authors such as Abramovitsh and Linetski, of writing he thought would stand comparison with works in other literatures.

In 1892 Rabinovitsh adopted the epistolary mode, in which he showed great virtuosity in his ironic handling of the constantly reborn but never gratified dreams of the average eastern European Jew. A series of monologues begun two years later featured the best known of all of Rabinovitsh's characters, Tevye der milkhiker ("Tevye the Milkman"), who narrates to Sholem Aleykhem the vicissitudes of his life. Tevye's tales epitomize the social strains and calamities suffered with faithful resignation by Jewish rural communities.

Rabinovitsh also published tales for the Jewish festivals and children's stories such as the well-known *Dos meserl* (1886; "The Penknife") in *Some Laughter, Some Tears*) and the *Motl Peyse dem khazns* cycle (1907–16; *Adventures of Mottel, the Cantor's Son*).

Returning to the novel in later life, Rabinovitsh dealt with the theme of the Jewish artist in *Blondzhende shtern* (1909–11; *Wandering Star*), giving a picaresque panorama of Yiddish theatre life stretching from eastern Europe to London's Whitechapel and Manhattan's Lower East Side. His comparatively few writings for the theatre include the posthumously published *Di goldgreber* (1908; "The Gold Diggers") and *Dos groyse gevins* (1916; "The Grand Prize"). In addition he adapted a number of his stories for the stage, including *Tevye der milkhiker.* (*Tevye* was made into a successful motion picture in 1939 and later was adapted as a musical comedy and motion picture under the title *Fiddler on the Roof.*)

THE 20TH CENTURY

To World War I. Together with Abramovitsh and Rabinovitsh, Yitskhek Leyb Perets is regarded as one of the three major classical writers in Yiddish literature. It was Perets who effectively ushered Yiddish literature into the modern era by exposing it to contemporary trends in western European art and literature. He was influenced by Polish neo-Romantic and Symbolist writings, and under their impact he lent new expressive force to the Yiddish language in numerous stories collected as *Khsidish* (1908; "Hasidic Tales") and *Folkstimlekhe geshikhten* (1908; "Folktales"). In these stories Hasidic material is viewed obliquely from the standpoint of a secular literary intellect and becomes the vehicle for an elegiac contemplation of traditional Jewish values.

Perets played an important moderating role as deputy

chairman at the Yiddish Conference that assembled at Czernowitz in 1908 to promote the status of the language and its culture. He is also remembered for the encouragement that he gave to a whole generation of younger writers who flocked to his home in Warsaw.

Perets and several other writers participated in the extraordinary burgeoning of literary activity that manifested itself above all in the foundation of literary periodicals with aesthetic programs. Particularly influential were the *Literarishe monatshriftn* ("Monthly Literary Review"), four issues of which appeared in Wilno (Vilnius) in the spring of 1908, carrying contributions by Perets, Der Nister (pseudonym of Pinkhes Kahanovich), Perets Hirshbeyn, and Sholem Asch (also spelled Sholem Ash).

Effects of World War I on Yiddish culture

World War I and its aftermath transformed Yiddish cultural geography. The war itself severely hampered contacts between the Jewish heartland in eastern Europe and nascent Yiddish intellectual life in the New World, while the Bolshevik Revolution, the Russian Civil War, and the ensuing Russo-Polish War severed the Soviet centres from literary activities in the resurgent Polish Republic. Furthermore, an ideological exchange took place, with Jewish intellectuals both fleeing from and migrating to the Soviet Union. Consequently, in dealing with Yiddish literature after World War I, it is appropriate to give separate attention to developments in the three major cultural centres.

After World War I. *The Soviet Union.* Of all the prewar Jewish parties in Russia, the most uncompromising in their support for Yiddish had been the members of the Jewish Labour Bund. Like the *maskilim* before them, the Bundists saw the language as a means to an end, in this case Socialism. The majority of the Bundists eventually joined forces with the Bolsheviks and took control of Jewish cultural institutions in the Soviet Union. While Hebrew literature and other supposedly chauvinist aspects of traditional Jewish culture were ruthlessly suppressed, Yiddish writers enjoyed unparalleled facilities. Before the war the Bundists had been bitterly opposed to the art-for-art's-sake trends in modernist Yiddish literature, but in the era immediately following the revolution much of what was published had, in fact, been written earlier and was Impressionist or Symbolist in style. Some of the best of this writing appeared in two important collections published in Kiev during the turbulent Russian Civil War era. *Eygns* (1918 and 1920; "Our Own") was edited by Dovid Berglson and Der Nister, while *Der oyfgang* (1919; "Ascent") was edited by Dovid Hofshteyn. In addition to works by the editors, these collections included significant contributions by Leyb Kvitko and Perets Markish that were stylistically innovative; at the same time they drew heavily on the themes of Russian Futurism and recapitulated Romantic and Expressionist developments in the European lyric that had previously been absent from Yiddish literature. All of these writers emigrated in 1920 or soon after but returned to the Soviet Union during the era of the New Economic Policy, when emphasis was placed on the need to win support among the more sympathetic of the émigré intellectuals.

Dovid Berglson (also spelled David Bergelson) had first made a name for himself with the short story *Arum vokzal* (1909; "At the Railway Station"; translated as "At the Depot" in *A Shtetl and Other Yiddish Novellas,* 1973) and with his masterpiece, *Nokh alemen* (1913; *When All Is Said and Done*), an impressionistic novel that brilliantly captures the atmosphere of unfulfilled longing in a Ukrainian provincial town. While in Berlin in 1924 he and Der Nister edited *Der Milgroym* ("Pomegranate"), one of the most impressive Yiddish literary journals ever produced. Increasingly, however, he thought of the Soviet Union as the only place where Yiddish literature could survive, and he went on to edit *In shpan* (1926; "In Harness"), a pro-Soviet journal that was intended to offer émigré writers an opportunity to align themselves with the supposed march of history.

Der Nister had been known as the author of brilliant Symbolist stories such as *Kleopatre* (1908; "Cleopatra"). In 1929 he published in *Di royte velt* ("The Red World") an extraordinary story entitled "Unter a ployt" ("Under a Fence"), a complex, phantasmagoric tale that expresses the agonies of artistic submission to external repression and perhaps best articulates the quintessence of Jewish intellectual life in the Soviet Union in those years.

In 1929 ideological rigidity once again gained the upper hand. Socialist Realism became the watchword and Yiddish writers increasingly found themselves accused of "bourgeois nationalism." During the 1930s the rate of Yiddish publishing actually increased, but it consisted largely of simplistic paeans to Stalin and to the system. The more sensitive writers felt themselves limited to the translation of foreign classics, to the production of "corrected" versions of earlier work, and to historical topics. Even within these restraints some remarkable works were produced, such as Berglson's semiautobiographical novel *Bam Dnyeper* (1932, 1940; "By the Shores of the Dnepr") or Der Nister's outstanding genealogical chronicle *Di mishpokhe Mashber* (1939; "The Mashber Family"), the action of which is set in the 1870s and which thereby sidesteps ideologically sensitive areas. Most remarkable perhaps among Yiddish publications of these years was *Zelmenyaner* (1929–30; "The Zelmenians") by Moyshe Kulbak, who was almost the only writer who dared to look at contemporary reality with a critical eye.

Many writers were victims of the political purges of the 1930s; "proletarian" or Marxist orthodoxy was no guarantee against arrest. The World War II years brought with them a renewed freedom for Yiddish authors to write about Jewish aspirations and causes. Soon after the war, however, the Zhdanovite repression bore down with particular severity on Yiddish cultural life, and by 1948 virtually all of the leading figures of the Yiddish intelligentsia had been arrested. Some died in prison. Almost all those still alive on Aug. 12, 1952, were shot on Stalin's orders.

Political purges of Yiddish writers

In 1955 and 1956 many of Stalin's victims were posthumously "rehabilitated," and since then Yiddish books and periodicals have appeared on a limited scale.

Poland. During the interwar years the Republic of Poland, independent once again after an interval of more than 120 years, together with Romania and Lithuania constituted the most fertile of the Yiddish cultural areas. An exponential increase in the number of talented writers at work produced a wealth of literary developments existing side by side. Naturalism was exemplified by Oyzer Varshavski's novel *Shmuglars* (1920; "Smugglers"), which depicts underworld life during the German occupation. Shloyme Zaynvl Rapoport, who wrote under the name of S. Ansky, was much influenced by the neo-Romanticism of Perets. His play *Der dibek* (1919; translated as "The Dybbuk" in *The Dybbuk and Other Great Yiddish Plays,* 1966) was performed by the celebrated Vilna Troupe in Warsaw and was received with great acclaim. It went on to attract international attention with performances in translation in Kraków, Berlin, Vienna, and New York City, all in 1925. (Mikhl Vashinski's screen version of *Der dibek* [1937] is perhaps the most successful of all the many Yiddish films made in Poland between the wars.)

The most self-conscious break with the past was made by the Expressionists. In 1919, writing in his short-lived but influential journal *Jung-yidish,* Moyshe Broderzon described the group of exuberant iconoclasts to which he belonged as a "*freylekhe . . . khalyastre*" or "merry gang," and this appellation became the title for the almanac *Khalyastre,* published in Warsaw and Paris in 1922–24, in which they proclaimed their modernist creed. The main protagonists in addition to Broderzon were Uri-Tsvi Grinberg, Melekh Ravitsh, and Perets Markish, who had gone to Warsaw from Kiev in 1921. Influenced both by the Futurism of the Russian revolutionary poet Mayakovsky and the Expressionism of the German Jewish writers Werfel and Else Lasker-Schüler, they sought to participate in the general European modernist movement and to respond to the anguish and chaos of the postwar world with universal images of apocalyptic pessimism. It was in Warsaw also that Markish first published his collection of poems entitled *Di kupe* (1921; "The Heap"), which is a Kaddish, a lament for the victims of a pogrom whose mutilated corpses lie heaped in a Ukrainian market square.

Khalyastre writers in Warsaw

Di kupe represented an important station in the history of Jewish artistic responses to anti-Semitism that

had included the 17th-century *lider* and Ḥayyim Naḥman Bialik's famous Hebrew poem on the Kishinyov pogrom of 1903. Grinberg, who in 1918 had himself narrowly escaped death in a pogrom in Lvov, voiced a more strident reaction in his *Uri-Tsvi farn tseylem* ("Uri-Zvi Before the Cross"), which he published in the second issue of his journal *Albatros* (1922). Grinberg eventually turned his back on both Europe and Yiddish in order to become a Hebrew poet in Palestine. Markish's Socialist ideals took him back to the Soviet Union, while Ravitsh left Poland and traveled widely before settling in Canada.

An associate of the group, while it lasted, was Yisroel-Yeshue Zinger (known in English as Israel Joshua Singer). He was joint editor of the first issue of *Khalyastre,* and he contributed to it an impressionistic story, *In der fintster* ("In the Dark"), written in Kiev during the Russian Civil War. Zinger, however, soon moved away from his neo-Romantic beginnings toward Realism. A semiautobiographical novel, *Shtol un ayzn* (1927; *Blood Harvest,* U.S. title *Steel and Iron*), reflects his wartime experiences. In *Yoshe Kalb* (1932) Zinger returned to his roots and wrote a novel of repressed sexual passion set amid the corruption and hypocrisy of a tyrannical Ḥasidic court. After the triumphant success of a stage version produced in New York City by Maurice Schwartz, Zinger emigrated to the United States. It was there that he wrote his masterpiece, *Di brider Ashkenazi* (1935; *The Brothers Ashkenazi*), which traces the antagonisms of two brothers against the background of the development of the textile industry in Łódź from the end of the Napoleonic era to the rebirth of the Polish republic.

Itsik Manger was born in Austrian Bukovina and began writing in Romania, but he moved in 1928 to Warsaw, where a year later he published his first book of collected verse. His major achievements were *Khumesh lider* (1935; "Pentateuch Songs") and *Megile lider* (1936; "Songs of the Book of Esther"), in which he feigns the naïveté of an itinerant minstrel and draws on the Purim play tradition to give an anachronistic and vivid account of biblical stories.

The rich and varied Yiddish literary culture of Poland was brought to an abrupt and tragic end by the Nazi invasion in 1939. Nevertheless, poems, plays, and songs continued to be written in the ghettos and camps, and a small proportion survives.   (H.F.D.)

The United States. With the 19th-century migrations to the United States, and especially to the Lower East Side of New York City, Yiddish literature made its appearance in the New World. A volume of exhortatory Haskalah verse appeared as early as 1877. This early beginning was followed by a generation of "sweatshop poets." Moris Vintshevski represented a transition from the Haskalah to socialism. He arrived in the United States in 1898 having already made a reputation for himself in London as a writer of propagandistic verse. Moris Roznfeld, like many of his readers, also came to New York City via the East End of London. He worked for many years in the tailoring shops of both cities. One of his famous poems, "Mayn yingele" (1887; "My Little Boy"), expresses a worker's estrangement from his family, resulting from endless hours spent in a sweatshop.

Avrom Lyesin and Avrom Reyzn made a more ironic and Romantic contribution to the development of Yiddish verse in America, while Yehoash Shloyme Blumgartn, who wrote under the name Yehoash, captured the sights and sounds of the metropolis and introduced the world of nature to the Yiddish lyric in the New World. His supreme achievement was a meticulous and scholarly translation of the Old Testament into modern Yiddish.

A significant change of direction occurred with the emergence of Di Yunge, a group of young poets associated with the journal *Di yugnt* ("Youth") that was published in New York City in 1907–08. They had been influenced by the Jewish Labour Bund and the revolutionary ferment in Russia, but when they went to the United States after the disappointments of the failed revolution of 1905 they no longer had any patience with the tendentious rhyming of their predecessors. The paradox of their position was that while their daily experience remained that of immigrant working-class life, they viewed it very largely from the perspective of European aestheticism. They were linguistic purists and also adept translators of the French, German, and Russian Symbolists who were their inspiration. The main protagonists of this movement were Mani Leyb, Zishe Landoy, and Moyshe Leyb Halpern. Another who was embraced by the movement was H. Leivick, pseudonym of Leyvik Halpern, who was best known for his verse drama *Der goylem* (1921; "The Golem"). For the most part Di Yunge were unacquainted with English literature, but Yisroel-Yankev Shvarts (I.J. Schwartz) translated Walt Whitman's poetry and adopted something of his manner in the epic poem *Kentoki* (1925; "Kentucky"), in which the exoticism and the wide open horizons of the American South entered Yiddish literature for the first time.

After World War I a more radical rebellion challenged the innovations of Di Yunge. In the anthology *In zikh* (1920; "Introspection") Arn Glants-Leyeles, Yankev Glatshteyn, and Nokhem Minkov asserted that the world exists only insofar as it is reflected in subjective impressions, each of which demands its own unique formal expression, ideally in free verse. Unlike Di Yunge, the Inzikhistn, as they came to be called, had attended universities in London and New York City and were influenced by contemporary English and American literature, in particular by Ezra Pound, T.S. Eliot, Wallace Stevens, and the Imagists. Glatshteyn was among the finest Yiddish writers of the 20th century. One of his later collections, *Shtralndike yidn* (1946; "Radiant Jews"), expresses sadness and despair following the Holocaust. Y.L. Teller, a younger poet, also confronted the political events of the time, in, for example, *Lider fun der tsayt* (1940; "Poems of the Age").

Sholem Ash became the first Yiddish author to have a truly international following. He visited the United States for the first time in 1910 and spent most of the rest of his life there. He moved from genial portrayal of life in eastern Europe in *A shtetl* (1904) and in his colourful underworld novel *Motke ganev* (1917; *Mottke the Thief*) to American locations with *Onkl Mozes* (1918; *Uncle Moses*) and several historical novels. Ash became the subject of controversy when he chose to write novels about early Christianity, so much so that of his trilogy published in English as *The Nazarene* (1939), *The Apostle* (1943), and *Mary* (1949) only the first volume appeared in the original Yiddish, as *Der man fun Netseres* (1943). Critics remained hostile to his subsequent work, including his most successful novel, *Ist river* (1946; *East River*), which looks with sanguine idealism at interaction between Irish and Jewish immigrants of the Lower East Side at the turn of the century.

Lamed Shapiro (pen name of Levi Yeshue Shapiro) and Yosef Opatoshu (pen name of Yoysef Meyer Opatovski) were prose writers of the same generation as Ash who migrated to the United States in their 20s. Shapiro achieved notoriety with a brilliant series of stories constituting a psychopathology of the pogrom, in which the action is seen through the eyes of the perpetrators of the violence. Opatoshu wrote realistic stories set in New York City and historical novels.

Chaim Grade, who lived in Vilnius until World War II, became a leading figure in the Yung-Vilne movement of the late 1930s. Grade published several highly esteemed volumes of poetry, such as *Doyres* (1945; *Generations*). After his arrival in New York in 1948, he also published novels—many of which have been translated into English—and the philosophical post-Holocaust story "Mayn krig mit Hersh Rasseyner" ("My Quarrel with Hersh Rasseyner").

Since World War II, the only Yiddish author to achieve world renown has been Yitskhek Basheyvis, known to his English readers as Isaac Bashevis Singer, who was awarded the Nobel Prize for Literature in 1978. Born in Poland in 1904, he moved to New York City in 1935. His best novel is perhaps the early, experimental *Der sotn in Goray* (1935; *Satan in Goray*), which begins as a historical novel. As it recreates the aura following the massacres instigated by Bohdan Khmelnytsky in 1648, it refers to the false messiah Shabbetai Tzevi. (Bohdan Khmelnytsky was a Cossack leader who led an uprising against Polish landowners; his forces also destroyed hundreds of Ukrainian Jewish com-

Works of Sholem Ash

Works of I.B. Singer

"Sweatshop poets"

Innovations of Di Yunge

munities.) Revolving around a case of possession by a dybbuk, or disembodied spirit, the novel anticipates Singer's later fascination with demons. The final segment, which purports to be the text of a document from the 17th century about "the dybbuk of Goray," is stylistically interesting for its deliberate archaisms. Singer's best-known work is "Gimpl Tam" ("Gimpel the Fool," written in the mid-1940s but first published in 1953; Eng. trans. in *Gimpel the Fool and Other Stories* [1957]), a short story that was powerfully translated by the American novelist Saul Bellow. Using first-person narrative—by a simple man who allows himself to be duped by the community—it evokes the shtetl in a humorous and nostalgic manner. Singer's stories were regularly published in the Yiddish newspaper *Forverts* and in *The New Yorker*; they appealed to American readers who sought to find a connection to eastern European life before the Holocaust.

<p style="margin-left:2em">Yiddish theatre in the United States</p>

Yiddish theatre arrived in the United States by way of London, where it had enjoyed a brief heyday in the 1880s. The first professional production in the United States took place in 1882 (despite much outraged protest on the part of New York City's German Jews) when the young Boris Tomashevsky made his debut in Goldfadn's *Koldunye* ("The Witch"). On the whole, artistic standards were not high, but the efforts of Yankev (Jacob) Gordin brought a considerable improvement. His *Sibirye*, which opened in November 1891, and *Der pogrom in Rusland*, produced two months later, brought a purer Yiddish as well as more serious and realistic content to the Yiddish stage, though his work was often marred by melodramatic moralizing. In his prolific output he frequently contented himself with free adaptations from classical English, German, and Russian drama. His most successful works were *Der yidisher kenig Lir* (1892), based on Shakespeare's *King Lear*, and what is perhaps the most popular play in the entire Yiddish repertoire, *Mirele Efros* (1898), which reworks the same theme with a female protagonist.

The greatest achievements of Yiddish theatre took place in the years following World War I. Dramatists such as Sholem Ash, Dovid Pinski, and Perets Hirshbeyn arrived from Europe and began working with theatre groups subsidized by Yiddish cultural organizations. A major impact was also made by European touring companies such as the Vilna Troupe. Hirshbeyn wrote rural idylls such as *A farvorfn vinkl* (1912; "A Secluded Corner") and *Grine felder* (1916; "Green Fields"), which reflected his experience of Jewish farming life both in his native Byelorussia and in the Catskill Mountains. Both plays were successfully staged in New York City by Yankev Ben-Ami, who had worked in Hirshbeyn's own company in Odessa before the war. While studying in Berlin, Pinski had been influenced by the Naturalist drama of the prolific German writer Gerhart Hauptmann. Pinski arrived in the United States in 1899 and continued his studies of German literature at Columbia University. His *Der oytser* (1906; *The Treasure*) is an ironic comedy satirizing avarice in a Russian shtetl. It was given its premiere performance in a German translation by the German-Jewish theatrical director Max Reinhardt in Berlin and became an international success. In *Dovid hameylekh un zayne vayber* (1914; "King David and His Wives") Pinski depicts the growing cynicism and hedonism of the King who, nonetheless, in old age achieves an almost Faustian insight into the elevation that comes from striving after an ideal. In 1949 Pinski, who had for decades been active in the Poalei Zion movement, moved to Haifa, where he became the focus of the Yung-Yisroel ("Young Israel") group.

<p style="margin-left:2em">Survival of Yiddish in Israel</p>

Israel. Arguably the most important Yiddish writer in Israel during the 20th century was the poet Avrom Sutskever (or Abraham Sutzkever). Like Chaim Grade, he was involved with the Yung-Vilne group. Sutskever lived for several years in Warsaw, where he published his first book of poetry in 1937. He escaped from the Vilna ghetto in 1943 and wrote poems about his experiences. Some of his poetry that responds to the Nazi genocide is contained in *Di festung* (1945; "The Fortress" or "The Prison") and in *Lider fun geto* (1946; "Poems from the Ghetto"). After

Sutskever moved to Palestine in 1947, he continued Yiddish literary culture in Israel and around the world by editing the journal *Di goldene keyt* (1949–96; "The Golden Chain"). Other Yiddish writers in Sutskever's group Yung-Yisroel were Shlomo Vorsoger, Tzvi Eisenman, Rivka Basman, and Rokhl Fishman.

Rikudah Potash was born in Poland and moved to Palestine in 1934. She published poetry in Poland and in Israel, including the volume *Moyled iber Timna* (1959; "New Moon over Timna"). Both her sense of fantasy and her knowledge of art history enrich this collection of poems. Leyb Rokhman settled in Jerusalem in 1950, where he tried to carry on both the Ḥasidic tradition and the secular culture of prewar Poland. His second book, *Mit blinde trit iber der erd* (1968; "With Blind Steps over the Earth"), expresses the psychological complexities of life as a Holocaust survivor. Yosl Birshteyn, born in Poland and going to Israel in 1950 by way of Australia, published poems, novels, and stories in Yiddish and Hebrew, including the novel *Der zamler* (1985; "The Collector"). Tsvi Kanar survived three years in a concentration camp before moving to Palestine in 1946. In 1980 he began writing fiction in Yiddish; among his books are *Ikh un lemekh* (1994; "Lemekh and I") and *Opgegebn broyt* (1996; "Returned Bread" or "Returning the Favour"). Lev Berinsky was a Russian poet who switched to Yiddish. Among his Yiddish works are the collections *Der zuniker veltboy* (1988; "The Sunny World-Structure") and *Fishfang in Venetsie* (1996; "Fishing in Venice").

Women writers. In the 20th century women began to contribute greatly to Yiddish literature. Among the more important writers are the poets Anna Margolin (*Lider* [1929; *Poems*]), Celia Dropkin, Kadia Molodowky, and Malka Heifetz Tussman. Selections of Tussman's poetry appear in English translation in *With Teeth in the Earth* (1992).

Yiddish and Hebrew have switched positions in the secular life of Ashkenazic Jewish communities. Until the Holocaust, Yiddish was the dominant vernacular of the Jews in Europe, while Hebrew was the largely unspoken, "high" literary language of scripture and prayer. Afterward, however, Hebrew was revived as the vernacular in Israel, and Yiddish began to lose its voice. Few of the secular Yiddish authors and scholars of the 21st century will have learned Yiddish as their mother tongue.   (H.F.D./K.F.)

BIBLIOGRAPHY. Critical overviews of Yiddish literature, theatre, and film include KEN FRIEDEN, *Classic Yiddish Fiction: Abramovitsh, Sholem Aleichem, and Peretz* (1995); BENJAMIN HARSHAV, *The Meaning of Yiddish* (1990); DAN MIRON, *A Traveler Disguised: The Rise of Modern Yiddish Fiction in the Nineteenth Century* (1996), and *The Image of the Shtetl and Other Studies of Modern Jewish Literary Imagination* (2000); DAVID ROSKIES, *A Bridge of Longing: The Lost Art of Yiddish Storytelling* (1995); NAHMA SANDROW, *Vagabond Stars: A World History of Yiddish Theater* (1996); and RUTH WISSE, *I.L. Peretz and the Making of Modern Jewish Culture* (1991). J. HOBERMAN, *Bridge of Light: Yiddish Film Between Two Worlds* (1991), discusses many films based on literary works.

Anthologies of Yiddish literature in English translation, with useful notes and introductions include FRIEDA FORMAN *et al.* (eds.), *Found Treasures: Stories by Yiddish Women Writers* (1994); HENRY GOODMAN (ed. and trans.), *The New Country: Stories from the Yiddish About Life in America* (2001); ELIEZER GREENBERG (ed.), *Ashes Out of Hope: Fiction by Soviet-Yiddish Writers* (1977); IRVING HOWE and ELIEZER GREENBERG (eds.), *A Treasury of Yiddish Stories*, rev. and updated (1990); JOACHIM NEUGROSCHEL (ed. and trans.), *The Dybbuk and the Yiddish Imagination: A Haunted Reader* (2000), and *No Star Too Beautiful: Yiddish Stories from 1382 to the Present* (2002); and RUTH R. WISSE (ed.), *A Shtetl and Other Yiddish Novellas*, 2nd ed. (1986). NAHMA SANDROW (ed. and trans.), *God, Man, and Devil: Yiddish Plays in Translation* (1999), is a good introduction to Yiddish theatre.

Yiddish poetry has been less amply represented, but useful volumes are JULES CHAMETZKY *et al.* (eds.), *Jewish-American Literature: A Norton Anthology* (2001); BENJAMIN HARSHAV and BARBARA HARSHAV (eds.), *American Yiddish Poetry: A Bilingual Anthology* (1986); IRVING HOWE and ELIEZER GREENBERG (eds.), *A Treasury of Yiddish Poetry* (1976); IRVING HOWE, RUTH R. WISSE, and KHONE SHMERUK (eds.), *The Penguin Book of Modern Yiddish Verse* (1987); and AARON KRAMER (ed. and trans.), *The Last Lullaby: Poetry from the Holocaust* (1998).   (K.F.)

Zoroastrianism and Parsiism

Zoroastrianism is the major ancient, pre-Islāmic religion of Iran. It survives there in isolated areas but also, more prosperously, with the Parsees, or Parsis (hence Parsiism), of India, descendants of immigrants who went there from Iran some time after the Muslim conquest. In modern times, a few adherents have transported the religion into the West. For a discussion of the context in which Zoroastrianism arose, see MIDDLE EASTERN RELIGIONS, ANCIENT: *Iranian religions*.

This article is divided into the following sections:

NATURE AND SIGNIFICANCE

The ancient Greeks saw in Zoroastrianism the archetype of the dualistic view of the world and of man's destiny. Zoroaster was supposed to have instructed Pythagoras in Babylon and to have inspired the Chaldean doctrines of astrology and magic. It is likely that Zoroastrianism influenced the development of Judaism and the birth of Christianity. The Christians, following a Jewish tradition, identified Zoroaster with Ezekiel, Nimrod, Seth, Balaam, and Baruch, and even, through the latter, with Christ himself. On the other hand, Zoroaster, as the presumed founder of astrology and magic, could be considered the arch-heretic. In more recent times the study of Zoroastrianism has played a decisive part in reconstructing the religion and social structure of the Indo-European peoples.

Mono-
theism and
dualism

Though Zoroastrianism was never, even in the thinking of its founder, as aggressively monotheistic as, for instance, Judaism or Islām, it does represent an original attempt at unifying under the worship of one supreme god a polytheistic religion comparable to those of the ancient Greeks, Latins, Indians, and other early peoples.

Its other salient feature, namely dualism, was never understood in an absolute, rigorous fashion. Good and Evil fight an unequal battle in which the former is assured of triumph. God's omnipotence is thus only temporarily limited. In this struggle man must enlist because of his capacity of free choice. He does so with his soul and body, *not* against his body, for the opposition between good and evil is not the same as the one between spirit and matter. Contrary to the Christian or Manichaean (from Manichaeism—a Hellenistic, dualistic religion founded by the Iranian prophet Mani) attitude, fasting and celibacy are proscribed, except as part of the purificatory ritual.

Man's fight has a negative aspect, nonetheless: he must keep himself pure; *i.e.*, avoid defilement by the forces of death, contact with dead matter, etc. Thus Zoroastrian ethics, although in itself lofty and rational, has a ritual aspect that is all-pervading. On the whole, Zoroastrianism is optimistic and has remained so even through the hardship and oppression of its believers.

HISTORY

Pre-Zoroastrian Iranian religion. The religion of Iran before the time of Zoroaster is not directly accessible, for there are no reliable sources more ancient than the prophet himself. It has to be studied indirectly on the basis of later documents and by a comparative approach. The language of Iran is closely akin to that of northern India, and hence the people of the two lands probably had common ancestors—the Indo-Iranians, or Aryans. The religion of the latter has been reconstructed by means of common elements contained in the sacred books of Iran and India: mainly the Avesta and the Vedas. Both collections exhibit the same kind of polytheism, with many of the same gods, notably the Indian Mitra (the Iranian Mithra), the cult of fire, sacrifice by means of a sacred liquor (*soma* in India, in Iran *haoma*), and other parallels. There is, moreover, a list of Aryan gods in a treaty concluded about 1380 BC between the Hittite emperor and the king of Mitanni. The list includes Mitra and Varuṇa, Indra, and the two Nāsatyas. All of these gods also are found in the Vedas, but only the first one in the Avesta, except that Indra and Nāñhaithya appear in the Avesta as demons; Varuṇa may have survived under another name. Important changes, then, must have taken place on the Iranian side, not all of which can be attributed to the prophet.

Daivas and
asuras

The Indo-Iranians appear to have distinguished, from among their gods, the *daiva* (Indo-Iranian and Old Persian equivalent of Avestan *daeva* and Sanskrit *deva*, related to the Latin *deus*), meaning "heavenly," and the *asura*, a special class with occult powers. This situation was reflected in Vedic India; later on, *asura* came to signify, in Sanskrit, a kind of demon, because of the baleful aspect of the *asura*'s invisible power. In Iran the evolution must have been different: the *ahura*s were extolled, to the exclusion of the *daeva*s, who were reduced to the rank of demons.

The reformation of Zoroaster. Zoroaster (Zarathushtra) was a priest of a certain *ahura* (Avestan equivalent of Sanskrit *asura*) with the epithet *mazdā*, "wise," whom Zoroaster mentions once in his hymns with "the [other] *ahura*s." Similarly, Darius I (522–486) and his successors worshipped Auramazda (Ahura Mazdā) "and the other gods who exist" or "Ahura Mazdā, the greatest god." The two historically related facts are evidently parallel: on both sides the rudiments of monotheism are present, though in a more elaborate form with the prophet Zoroaster.

It has not yet been possible to place Zoroaster's hymns, the *Gāthā*s, in their historical context. Not a single place or person mentioned in them is known from any other source. Vishtāspa, the prophet's protector, can only be the namesake of the father of Darius, the Achaemenid king. All that may safely be said is that Zoroaster lived somewhere in eastern Iran, far from the civilized world of western Asia, before Iran became unified under Cyrus II the Great. If the Achaemenids ever heard of him, they did not see fit to mention his name in their inscriptions nor did they allude to the beings who surrounded the great god and were later to be called the *amesha spenta*s, or "bounteous immortals"—an essential feature of Zoroaster's doctrine.

Religion under the Achaemenids was in the hands of the Magi, whom Herodotus describes as a Median tribe with special customs, such as exposing the dead, fighting evil animals, and interpreting dreams. Again, the historical con-

nection with Zoroaster—whom Herodotus also ignores—is a hazy one. It is not known when Zoroaster's doctrine reached western Iran, but it must have been before the time of Aristotle (384–322), who alludes to its dualism.

Darius, when he seized power in 522, had to fight a usurper, Gaumata the Magian, who pretended to be Bardiya, the son of Cyrus the Great and brother of the king Cambyses. This Magian had destroyed cultic shrines, *āyadana*s, which Darius restored. One possible explanation of these events is that Gaumata had adopted Zoroastrianism, a doctrine that relied on the allegiance of the common people, and therefore destroyed temples or altars to deities of the nobility. Darius, who owed his throne to the support of some noblemen, could not help favouring their cult, although he adopted Auramazda as a means of unifying his empire.

Xerxes, successor to Darius, mentioned in one of his inscriptions how at a certain (unnamed) place he substituted the worship of Auramazda for that of the *daiva*s, which does not mean he opposed the *daeva* cult as such, as a true Zoroastrian would have done, but only that he eradicated somewhere—probably in Babylon—the cult of deities alien to the religion of the *ahura*s. It points to a change of attitude, compared with Cyrus' tolerance of alien religions, such as the Babylonian or the Jewish religions.

From Artaxerxes II (404–359/358) onward, the inscriptions mention, besides Auramazda, Mithra and the goddess Anahita (Anahit), which proves only a change of emphasis, not the appearance of new deities.

The Arsacid period. In consequence of Alexander's conquest, the Iranian religion was almost totally submerged by the wave of Hellenism. At Susa, for instance, which had been one of the capital cities of the Achaemenids but where the religion of Auramazda was not indigenous, the coinage of the Seleucid and Arsacid periods does not represent a single Iranian deity.

Then the Iranian religion gradually emerged again. In Commagene in the middle of the 1st century BC, gods bear combinations of Greek and Iranian names: Zeus Oromazdes, Apollo Mithra, Helios Hermes, Artagnes Herakles Ares. The first proof of the use of a Zoroastrian calendar, implying the official recognition of Zoroastrianism, is found some 40 years earlier at Nisa (near modern Ashkhabad in Soviet Turkmenistan). By then some form of orthodoxy must have been established in which Auramazda and the entities (powers surrounding him) adjoin other gods such as Mithra, the Sun, and the Moon.

In Persis (modern Fars), from the beginning of the Christian Era to the advent of the Sāsānians (early 3rd century AD), any allusion to the fire cult disappears. The coins seem to indicate, in not showing the fire altar, that the prince had lost interest in the Iranian religion.

The Sāsānian period. With Ardashīr, the future founder of the Sāsānian dynasty, the situation was different; and this may suggest that his religious zeal—as a hereditary priest of Staxr (Istaxr)—may have helped him seize power in his native province, even before he started attacking his Arsacid suzerain, Artabanus V.

Two persons are recorded, in different sources, as helping to establish Zoroastrianism under the first Sāsānians: Kartēr and Tansar. Whereas Kartēr is known through contemporary inscriptions, most of which were written by himself, Tansar (or Tosar) is only remembered in later books. The latter tell us that Tansar, an *ehrpat*, or theologian, undertook the task, under Ardashīr's command, of collecting the sacred texts and fixing the canon. Kartēr, who was already active under Ardashīr I but more so under Shāpūr and his successors, recounted his brilliant career, which reflects the birth of a hierarchy. He was still an *ehrpat* under Shāpūr, as he restored the "Mazdean religion . . . in the land of non-Iran reached by the horses and men of the king of kings." Under Hormizd he was made "*magupat* of Ormazd," a term apparently created for him and meaning "chief of the Magians of Auramazda." Under Bahrām I (AD 273–276), Mani, the founder of Manichaeism, who had enjoyed a degree of tolerance under the two preceding kings, was sacrificed to the interests of Zoroastrianism and died in prison. Bahrām II named Kartēr "Saviour of the Soul of Bahrām," elevated him to

the rank of the "grandees of the realm," and gave him the additional titles of "judge of the empire," "master of rites," and "ruler of the fire of Anahit-Ardashīr at Staxr and of Anahit the Dame." Promoted to the apex of his career, Kartēr persecuted "Jews, Buddhists, Brahmins, Nasoreans [Judeo-Christians?], Christians, Maktaks [Mandeans, Manichaeans?], and Zandīks [Mazdean heretics]." Narses (293–302), who began his struggle for power when Bahrām II was still on the throne, seems to have recovered the title of chief of the Staxr temple that his predecessor and adversary had surrendered to Kartēr. Under Shāpūr II, the high priest Aturpāt, at a council summoned to fix the text of the Avesta, proved the truth of his doctrine by submitting to the ordeal of molten metal poured on his breast and was victorious over all kinds of sectarians and heretics.

Under Bahrām V (420–438), presumably, the title *magupatān magupat* (chief magus of the chief magi) was created. Under Qobād (or Kavādh; 488–496 and 498/499–531), Iran traversed its gravest social and religious crisis under the impact of Mazdak. This reformer, whose doctrines were partly inspired by those of Mani, was granted an interview by Qobād—as Shāpūr I had received Mani a long time before, but with a more decisive success. Perhaps the King hoped that by abolishing property and the family he would reign over a docile mass. The Mazdakites favoured the abolition of all social inequalities, chiefly of private property, the main cause of all hatred. Everything was to be held in common, including women. These views directly threatened the rich as well as the Mazdean clergy, who soon understood this. Qobād was dethroned and replaced by his brother Jāmāsp. After two years in exile, Qobād recovered his throne, but he had been cured of his egalitarian views and decided to liquidate the Mazdakites.

Khosrow I continued the work of his father, Qobād, and thus the Mazdakite upheaval made way for a strong state and an established Mazdean Church. The religious books give Khosrow the unique title of *Anōsharvan,* "with the immortal soul," probably for having crushed Mazdakism and for enabling the "good religion" to triumph.

Khosrow II (590/591–628) married a Christian woman and may have been a Christian himself. He was superstitious and dabbled in astrology.

Post-Islāmic Iranian Zoroastrianism. Islām won a decisive victory at al-Qādisīyah in 635 over the armies of Yazdegerd III, the last Sāsānid. Islām, in principle, tolerated the ancient religion, but conversions by persuasion or force were massive in many provinces. Zoroastrianism fomented rebellion and brought persecutions upon itself. There were pockets of survival, notably in Persis, the ancient centre of the Achaemenian and Sāsānian empires. Books were produced to save the essentials of the religion from a threatened disaster. The disaster did occur but exactly why and how is not known. Zoroastrians, called Gabars by the Muslims, survived in Iran as a persecuted minority in small enclaves at Yazd and Kerman.

The Parsis in India. From the 10th century onward, groups of Zoroastrians emigrated to India, where they found asylum in Gujarāt. Their connection with their coreligionists in Iran seems to have been almost totally broken until the end of the 15th century. Reestablished in 1477, the connection was kept up chiefly in the form of an exchange of letters until 1768. Under British rule, the Parsis, who previously had been humble agriculturists, started to enrich themselves through commerce, then through industry. They became a most prosperous and "modern" community, centred in Bombay. Formerly they had adopted the language (Gujarati) and the dress of their Hindu milieu. Later they adopted British customs, British dress, the education of girls, and the abolition of child marriage. In their enterprises as well as in their charities they followed the example of the West. From the 19th century on, they were able to help their less favoured brethren in Iran, either through gifts or through intervention with the government.

They also adapted themselves to their Indian culture by minimizing what was repugnant to the Hindus, namely, blood sacrifice; and they surrendered to some extent to the vogue of astrology and to theosophy. On the other

[margin] Hellenistic syncretism

[margin] Mazdak and Mazdakism

hand, ever since they were attacked by Christian missionaries for their dualism, they have been emphasizing the monotheistic aspect of their doctrine.

BELIEFS AND MYTHOLOGY

The Avesta

Sources. Only the hymns, or *Gāthā*s, are attributable to Zoroaster. They are written in various metres and in a dialect different from the rest of the Avesta, except for seven chapters, chiefly in prose, that appear to have been composed shortly after the prophet's demise. All these texts are embedded in the *Yasna,* which is one of the main divisions of the Avesta and is recited by the priests during the ceremony of the same name, meaning "sacrifice." The *Visp-rat* ("All the Judges") is a *Yasna* augmented here and there by additional invocations and offerings to the *ratu*s (lords) of the different classes of beings. The *Vidēvdāt, or Vendidad* ("Law Rejecting the Daevas"), consists of two introductory sections recounting how the law was given to man, followed by 18 sections of rules. The *Siroza* enumerates the deities presiding over the 30 days of the month. The *Yasht*s (hymns) are each addressed to one of 21 deities such as Mithra, Anahita, or Verethraghna. The *Hadhoxt Nask* ("Section Containing Sayings") describes the fate of the soul after death. The *Khūrda Avesta,* or Small Avesta, is made up of minor texts.

The Avesta is, therefore, a collection of texts compiled in successive stages until it was completed under the Sāsānians. It was then about four times larger than what has survived. A summary of its 21 books, or *Nask*s (of which only one is preserved as such in the *Vidēvdāt*), is given in one of the main treatises written during the brief Zoroastrian renascence under Islām in the 9th century; the *Dēnkart,* the "Acts of the Religion." It is written in Pahlavi, the language of the Sāsānians.

Other works in Pahlavi include, besides a translation and commentary on the Avesta, the *Bundahishn* ("Primal Creation"), a cosmology. Most Pahlavi books are anonymous, such as *Mēnōk-i Khrat* ("Spirit of Wisdom"), a lucid summary of a doctrine based on reason, and the *Book of Artāy Virāf,* which describes Virāf's descent into the netherworld as well as heaven and hell and the pleasures and pains awaiting the virtuous and the wicked. There are also a few signed works, such as those of the two brothers Zātspram and Mānushchihr, or Mardān-Farrukh's *Shkand-Gumānīk Vichār* ("Final Dispelling of Doubts"), an apology of the Mazdean religion directed against Manichaeism, Christianity, Judaism, and Islām.

Finally, there are Zoroastrian books written in Persian, either in verse or in prose. The latter include the correspondence exchanged between Zoroastrians of Iran and India and the treatise entitled *'Olemā-ye Islām* ("The Doctors of Islām"), with decidedly Zurvanite tendencies.

Mithra

God. Zoroaster's silence on Mithra is not easy to interpret. Since this god was closely associated with Varuṇa in India and with Varuṇa's likely substitute in Iran, Zoroaster can hardly have ignored one-half of this divine pair without a definite purpose. Otherwise, it might be presumed that Mithra was included in the formula "Mazdā and the [other] *ahura*s"; however, Mithra is called in the Later Avesta (non-Gāthic) an *ahura;* so is Apām Napāt, a fire or brightness in the waters, corresponding to the Vedic Apām Napāt. As for Verethraghna (the entity or spirit of victory), it seems that since he took over the function of Indra, who was a *daeva,* he could not be called an *ahura;* but in order to mark his belonging to the world of *ahura*s he was called *ahuradāta,* "created by an *ahura*."

It is in the framework of the religion of the *ahura*s, hostile to the cult of the *daeva*s, that Zoroaster's message should be understood. He emphasized the central importance of his god, the wise Ahura, by portraying him with an escort of entities, the powers of all the other gods, in an array against the forces of evil.

The moral dualism expressed in the opposition Asha–Druj (truth–falsehood) goes back at least to Indo-Iranian times, for the Veda knows it too, as *ṛta–druh,* although the contrast is not as sharply defined as in the Avesta. Between these two principles, the Twin Spirits made an ominous choice, the Bounteous One becoming in thoughts, words, and deeds a partisan of Asha, *ashavan,* while the other

became *dregvant,* partisan of the Druj. After them it was the *daeva*s' turn; they all chose wrongly. Ever since, the *daeva*s have tried to corrupt man's choice also.

To the army of the *ashavan*s, headed by the Bounteous Spirit, was counterposed the host of the *dregvant*s, under the Destructive Spirit, Angra Mainyu. Each combatant faced his exact counterpart: the Good Mind opposing the Bad Mind and Aramaiti being countered by Taromaiti.

In this battle, the whole material universe is, through the entities, potentially enrolled, the Bounteous Spirit being the patron of man, Asha of fire, the Good Mind of the Ox, the Dominion of the metals, Aramaiti of the earth, Integrity and Immortality of the waters and plants. Moreover, since the entities are at once divine and human (because both the spiritual and material qualities of man partake of divine), everyone faithful to the wise Ahura can commune with him.

After Zoroaster, considerable changes occurred in the theology he had professed. The entities were reduced to mere deities, which were even separated into male and female. Never again were their names used to designate human faculties. This is probably a consequence of the resurgence of the ancient gods.

It is not known to what extent Zoroaster's system was meant to be exclusively the cult of Ahura Mazdā. In the Later Avesta all the gods he had ignored emerged again, such as Mithra, Airyaman (whom he had replaced by Sraosha), Anahita, Apām Napāt, Verethraghna, and Vayu. This vast pantheon, still nominally headed by Ahura Mazdā, is similar to the compromise that Darius, according to the interpretation cited above, made between the cult of Auramazda and that of the gods of the nobility.

Not only did Zoroaster's theology thus lose its exclusive position, but an internal change also modified its equilibrium and even threatened its very essence. The Bounteous Spirit was almost completely reabsorbed into Ahura Mazdā. Whereas in a *Yasht* the two Spirits fought each other, in the *Vidēvdāt* Ahura Mazdā and the Destructive Spirit opposed each other by creating, respectively, the good and the bad things. This profoundly affected Zoroaster's system, for Ahura Mazdā could no longer be the father of the Twin Spirits; he now faced, on equal terms so to speak, a sort of antigod. This alteration probably dates back at least to the 4th century BC, for Aristotle said in the *Peri philosophias* ("On Philosophy") that the Magi preached the existence of two principles, Oromasdes and Areimanios.

Cosmogony. In the cosmogony as expounded in the *Bundahishn,* Ormazd (Ahura Mazdā) and Ahriman are separated by the void. They seem to have existed from all eternity, when Ahriman's invidious attack initiates the whole process of creation. The question of their origin is ignored, but it was implied, ever since Ormazd had taken the place of his Bounteous Spirit in the struggle against the Destructive Spirit. Since Ahura Mazdā could no longer be the father of the two adversaries, the question of their origin was inevitable.

Zurvanism

A solution was provided by Zurvanism; it is Zurvān (Time) who is the father of Ormazd and Ahriman. But this solution upset the very essence of Mazdaism and was therefore condemned as heretical. Zurvanism was widely accepted, however, perhaps even prevalent, in Sāsānian times. Traces of it are found in Mazdean orthodoxy, some features of which cannot otherwise be explained.

In Mazdean orthodoxy, when Ormazd created the material world, he first produced from Infinite Light a form of fire, out of which all things were to be born. This form of fire is "bright, white, round, and visible from afar." Gayōmart, the Primal Man, was also conceived as spherical, in the image of the sky. Mānushchihr writes that "Ormazd, the lord of all things, produced from Infinite Light a form of fire whose name was that of Ormazd and whose light was that of fire." This phrase can be accounted for only as a clumsy adaptation of a Zurvanite text that must have said, in effect, that Zurvān created Ormazd.

The Mazdean quaternity can hardly be explained except as an adaptation of the Zurvanite one. The latter is attested in several texts citing, besides Zurvān, three other names given as those of separate gods but that must be hypostases

(essences) of the first one, also called in Manichaeism the god with four faces. Among the various forms under which the Zurvanite quaternity manifested itself, the one associating Zurvān with Light, Power, and Wisdom seems to be the origin of the Mazdean quaternity. Ormazd, in the *Bundahishn,* has three other names, namely Time, Space, and Religion. To obtain this quaternity, it was sufficient to replace Zurvān by Time, Light by Space, Wisdom by Religion, and Power by Ormazd and to put the latter at the end of the series.

The Mazdean quaternity is reflected in the calendar at Nisa in 90 BC. The Zurvanite speculation that preceded it probably dates back to the first centuries of the Arsacid period and thus was born in the wake of Hellenism and in connection with the spread of astrology.

Cosmology. In order to vanquish Ahriman, Ormazd created the world as a battlefield. He knew that this fight would be limited in time—it would last 9,000 years—and he offered Ahriman a pact to that effect. After they had created their respective material creations, Ahriman's first attack was defeated by Ormazd with the help of the Ahuna Vairya prayer (the most sacred Zoroastrian prayer), and he lay prostrate for another period of 3,000 years, the second in a total of four. He was then stirred up by the prostitute (Primal Woman) and went back to the attack, this time in the material universe. He killed the Primal Bull, whose marrow gave birth to the plants and whose semen was collected and purified in the moon, whence it would produce the useful animals. Ahriman then killed

Gayōmart, the Primal Man

Gayōmart, the Primal Man, whose body produced the metals and whose semen was preserved and purified in the sun. A part of it would produce the rhubarb from which the first human couple would be born.

The first human couple were perverted by Ahriman, and it is only with the advent of Zoroaster, after 3,000 years, that Ahriman's supremacy came to an end. Ormazd and Ahriman then fight on equal terms until Ormazd, at the end of the last 3,000 years, finally will triumph.

Concepts of man. The idea of man as a microcosm, already illustrated in the cosmogony, is further developed in the *Bundahishn.*

As a result of the aggressor's attack, man is mortal. But he does not die altogether. There are five immortal parts in him: *ahu* ("life"), *daēnā* ("religion"), *baodah* ("knowledge"), *urvan* ("soul"), and *fravashi* ("preexistent souls"). The latter term seems literally to mean "preeminent hero." The conception that caused this term to be applied to the "manes" (spirits) or *pitarah* of Iran is that of a defensive, protective power that continues to emanate from a chief even after death. This originally aristocratic notion seems to have been vulgarized in the same way as, in Greece, any dead person came to be considered a hero, or, in Egypt, an Osiris. Zoroaster ignored the *fravashi,* but he was familiar with the *daēnā.* The latter term meant "religion" in both its objective and subjective senses.

The afterlife

Indian and Iranian beliefs in the afterlife have many features in common, probably dating back to the Indo-Iranian period: a feminine encounter, a bridge with dogs watching it, a heavenly journey. In the ancient Indian texts, the *Upaniṣad*s, the soul is welcomed in heaven by 500 *apsara*s (cloud maidens). In Iran the soul meets his own religion (*daēnā*) in the form of a beautiful damsel if he has lived justly; otherwise, he meets a hideous hag.

Either before this encounter or after, according to the various texts, the soul must cross a bridge. This, with the young girl and the gods, is attested in India in the Yajurveda and the *Upaniṣad*s. In the *Gāthās* it is called the Bridge of the Requiter. It leads the good souls to paradise, but the bad ones fall into hell.

The soul has also to undergo a judgment; it appears before Mithra and his two companions, Sraosha and Rashnu. Finally it ascends through successive stages representing respectively its good thoughts (the stars), good words (the moon), and good deeds (the sun) to the paradise (of infinite lights). In the Veda it is said only that the sojourn of the good deed is beyond the path of the sun. In paradise the soul is led by Vohu Manah, the Good Mind, to the golden throne of Ormazd.

Hell also has, symmetrically, four levels. And there is,

for the souls whose good actions exactly balance their evil ones, an intermediate place.

Eschatology. Zoroaster used to invoke saviours who, like the dawns of new days, would come to the world. He hoped himself to be one of them. After his death, the belief in coming saviours developed. Zarathushtra (Zoroaster) was expected to return, if not personally, at least in the form of his three sons who would be born, at intervals of a thousand years, from his semen. The last of these saviours, Astvat-ereta, or justice incarnate, was also simply called the Saviour (Saoshyans).

Only in the Pahlavi books is this theme systematically developed. It is dominated by the idea of a final return to the initial state of things. The first human couple had at first fed on water, then on plants, on milk, and at last on meat. The people in the last millennia will, at the advent of the three successive saviours, abstain in the reverse order from meat, milk, and plants to keep finally only water. The primeval combatants also have their counterparts at the end of time. The dragon that was killed in order to liberate the imprisoned waters will appear again at the resurrection to be killed by another hero. In the last great struggle, the host of good and the host of evil will vie with each other, and each soldier of Ormazd will defeat and kill his own special adversary. This will restore the state of peace that had prevailed initially. The wicked will then submit to an ordeal of molten metal and fire. Fire and Airyaman will cause the metals of the mountains to melt and to flow down as a river of fire. The whole of resuscitated mankind must traverse it; it will burn only the wicked, whereas to the just it will be as sweet as warm milk. The suffering of the wicked will last only three days, however, after which all mankind will enjoy much happiness. On the flattened earth (for the metal will fill in all the valleys), men and women, henceforth shadowless since they are sinless, will taste the bliss of family life. Hell will be sealed forever, and Ahriman will be either powerless or annihilated.

PRACTICES AND INSTITUTIONS

Cultic places. Although Herodotus wrote that the Persians had no temples, some have been found, in the shape of terraces or towers or square rooms. *Chahārtāq*s (sacred buildings with four gates or doors) are scattered over most of Iran. Permanent altars exist from the Sāsānian period and are depicted on coins with a burning fire.

The sacred fire

The Farnbag, Gushnasp, and Burzen-Mihr fires were connected, respectively, with the priests, the warriors, and the farmers. The Farnbag fire was at first in Khwārezm, until in the 6th century BC, according to tradition, Vishtāspa, Zoroaster's protector, transported it to Kabulistan; then Khosrow in the 6th century AD transported it to the ancient sanctuary of Kariyan in Fars. The latter, however, has not yet been identified. The Gushnasp fire, located at Shiz, was the ancient fire of the Magi (in Media), but it came to be the symbol of the monarchic and religious unity. The Burzen-Mihr fire never ranked as high as the other two because the peasants, unlike the kings and clergy, never possessed any sovereignty. Besides these individual designations, the fires were classified according to two categories: the Adurān, village fires; and the Varhrān, provincial and royal fires.

Magians

Priesthood. The Magians, though not originally Zoroastrian, apparently became acquainted with the prophet's teachings not later than the 4th century BC. They had the monopoly on religion at the Achaemenian court. The term magus was still used in the Arsacid period. Thereafter, under the Sāsānians, a hierarchy developed, with the creation of the *magupat,* or chief of magi, and of its superlative *magupatān magupat* (coined on the model of *shāhanshāh,* "king of kings"). The *ehrpat,* originally a religious teacher, was especially entrusted with the care of the fire. The modern equivalent of the word, *herbad* or *ervad,* designates a priest of the lower degree, who in the more important ceremonies only acts as the assistant priest. Above him is the *mobed.* Ranked above all of these functionaries is the *dastūr,* a kind of bishop, who directs and administers one or more important temples. Priesthood is hereditary, but all priests have to go through one

(Left) Stone relief of the Achaemenid period shows priest wearing mouth cover while
presiding at a sacrifice. (Right) Modern Zoroastrian priest wearing similar mouth cover while
tending a temple fire.

or more ceremonies of investiture over and above those
practiced by all the faithful.

Ceremonies. All young Parsis must be initiated when
they reach the age of seven (in India) or 10 (in Persia).
They receive the shirt (*sadre*) and the girdle (*kusti*), which
they are to wear their whole life.

There are three types of purification, in order of increas-
ing importance: the *padyab*, or ablution; the *nahn*, or
bath; and the *bareshnum*, a complicated ritual performed
at special places with the participation of a dog—whose
left ear is touched by the candidate and whose gaze puts
the evil spirits to flight—and lasting several days.

Penance entails reciting the *patet*, the firm resolve not to
sin again, and the confession of sins to a *dastūr* or to an
ordinary priest if a *dastūr* is not obtainable.

The chief ceremony, the *Yasna*, essentially a sacrifice of
haoma (the sacred liquor), is celebrated before the sacred
fire with recitation of large parts of the Avesta. There also
are offerings of bread and milk and, formerly, of meat
or animal fat.

The sacred fire must be kept burning continually and has
to be fed at least five times a day. Prayers also are recited
five times a day. The founding of a new fire involves a
very elaborate ceremony. There are also rites for purifica-
tion and for regeneration of a fire.

Burial rites. After death, a dog is brought before the
corpse; it should preferably be a "four-eyed" dog (*i.e.*,
it should have a spot above each eye, as this is said to
increase the efficacy of its look). The rite is repeated five
times a day. After the first one, fire is brought into the
room where it is kept burning until three days after the re-
moval of the corpse to the Tower of Silence. The removal
must be done during the daytime.

The interior of the Tower of Silence is built in three con-
centric circles, one each for men, women, and children.
The corpses are exposed there naked. The vultures do not
take long—an hour or two at the most—to strip the flesh
off the bones, and these, dried by the sun, are later swept
into the central well. Formerly the bones were kept in
an ossuary, the *astodān*, to preserve them from rain and
animals. The morning of the fourth day is marked by the
most solemn observance in the death ritual, for it is then
that the departed soul reaches the next world and appears
before the deities who are to pass judgment over it.

Festivals. Festivals, in which worship is an essential
part, are characteristic aspects of Zoroastrianism, a faith
that enjoins on man the pleasant duty of being happy. The
principal festivals in the Parsi year are the six seasonal
festivals, *Gahānbārs*, and the days in memory of the dead
at year's end. Also, each day of the month and each of
the 12 months of the year is dedicated to a deity. The
day named after the month is the great feast day of that
particular deity.

The New Year festival, Nōrūz, is the most joyous and
beautiful of Zoroastrian feasts, a spring festival in honour
of Rapithwin, the personification of noonday and summer.
The festival to Mithra, or Mehragān, was traditionally an
autumn one, as honoured as the spring feast of Nōrūz.

Ethics. The precepts of Mazdean ethics focus upon the
maintenance of life and the fight against evil. In order
to maintain life one must earn one's living by means of
cattle raising and agriculture, and one must procreate. To
fight against evil is to combat the demons and whatever
beings, men or animals, belong to them. The two points
of view seem to coincide, considering that the forces of
evil are the forces of death: good is opposed to evil as light
is to darkness, as life is to nonlife. The life precepts can
be transposed into fight precepts; for instance, eating and
drinking are interpreted by Zātspram as a struggle against
the she-demon Āz, "Concupiscence." The two points of
view, however, are also contradictory: how can man fight
the forces of evil without suppressing certain lives, such
as baleful animals? The second viewpoint prevails: Iran
ignores, even in theory, the universal respect of life that is
preached by Buddhism or that justifies the vegetarian diet
of Brahmanic India.

Social reasons (*e.g.*, the desire to maintain family priv-
ileges) apparently explain the development of consan-
guineous marriage, an acute form of endogamy.

Future life should be determined by the balance of the
good and evil deeds, words, and thoughts of the whole
life. This principle, however, is tempered to allow for hu-
man weakness. All faults do not have to be registered or
weighed forever on the scales. There are two means of ef-
facing them: confession and the transfer of supererogatory
merits (the equivalent of the Roman Catholic "Treasury
of Merits" of Christ and the saints). The latter is the jus-
tification for the prayers and ceremonies for the departed.

ICONOGRAPHY

There is no Zoroastrian art. Be it in the Achaemenid, Arsacid, or Sāsānian period, Iranian art was predominantly royal. Only one god is represented during the first period: Auramazda, as a winged disk hovering above the king. It is known, however, that Artaxerxes II introduced statues of Anahita into her temples, after the Greek fashion. In the Arsacid period, Greek models also served for the representations of Iranian gods ordered by the kings on reliefs or coins. In the Sāsānian period, deities were represented only in the giving of the royal investiture, as is the case with Ormazd and Anahita at Naqsh-e Rostam, or Ormazd and Mithra at Taq-e Bostan. The frequency of the bullman in Achaemenid and Sāsānid iconography may be due to the obviously royal character of this personage: on seals he wears a crown, and the Pahlavi text calls him Gopatshāh, "King of Gopat."

RELATION TO OTHER RELIGIONS

The debt of Israel to its Eastern neighbours in religious matters is easy to demonstrate on a few precise points of minor importance but less so in other more important points, such as dualism, angelology, and eschatology.

Isaiah 40–48 offers striking parallels with the *Gāthā* 44:3–5, as has been shown by Morton Smith. Besides the common procedure of rhetorical questions, there is the notion of a god who has created the world and, notably, light and darkness. The very idea of a creator god may be common to all of the western part of the Semitic world. But the notion that God created light and darkness appears in both prophets. It is true that Zoroaster associates light and darkness only to waking and sleep and that no Iranian text says that God created good and evil. Nevertheless, the juxtaposition, in Isaiah, of light–darkness with good–evil sounds remarkably Iranian.

After the exile, the traditional hope in a messiah-king of the House of David who would reestablish Israel as an independent nation and make it triumph over all enemies gave way gradually to a concept at once more universal and more moral. The salvation of Israel was still essential, but it had to come about in the framework of a general renewal; the appearance of a saviour would mean the end of this world and the birth of a new creation; his judgment of Israel would become a general judgment, dividing mankind into good and evil. This new concept, at once universal and ethical, recalls Iran so strongly that many scholars attribute it to the influence of that country. John R. Hinnells has seen this influence especially in the saviour's defeat of the demons, his gathering of men for the judgment scene, his raising of the dead, and his administration of the judgment. The occasion of this influence, according to Hinnells, may be found in the contacts between the Jews and the Parthians that were initiated in the 2nd century BC but that reached a climax in the middle of the 1st century BC.

Although Pythagoras cannot have been a pupil of Zoroaster, there are striking similarities of doctrine between Iran and Greece. Anaximander's world picture corresponds to that of the Avesta. Heraclitus seems to have been impressed, in Ephesus, by the practices of the Magi, if not by their theory on the fiery nature of the soul. This would account for the emergence, in 5th-century Greece, of the belief in the heavenly fate of the soul.

The search for an Iranian background to Gnosticism must be placed in a new perspective if the recent view that Gnosticism is really a Christian heresy is accepted.

CONCLUSION

Zoroastrianism is not the purely ethical religion it may at first seem. In practice, despite the doctrine of free choice, a Zoroastrian is so constantly involved in a meticulous struggle against the contamination of death and the thousand causes of defilement, and against the threat, even in his sleep, of ever-present demons, that he does not often believe that he is leading his life freely and morally.

Apart from this attitude, the belief in the power of destiny sometimes culminates in fatalism. The latter is easily associated with Zurvanism, itself sometimes tainted with materialism. In the *Mēnōk-i Khrat,* it is stated that "though one be armed with the valour and strength of wisdom and knowledge, yet it is not possible to strive against fate."

On the whole, however, as R.C. Zaehner notes, "the theological premises" of Zoroastrianism "are based on an essentially moralistic view of life."

BIBLIOGRAPHY. A wide-ranging introductory study is found in CYRUS R. PANGBORN, *Zoroastrianism: A Beleaguered Faith* (1982). Other studies include MARY BOYCE, *A History of Zoroastrianism* (1975–), *A Persian Stronghold of Zoroastrianism* (1977, reprinted 1989), *Zoroastrians: Their Religious Beliefs and Practices* (1979, reissued 1986), and *Zoroastrianism: Its Antiquity and Constant Vigour* (1992); JACQUES DUCHESNE-GUILLEMIN, "Zoroastrian Religion," in *The Cambridge History of Iran,* vol. 3, part 2 (1983), chapter 23, pp. 866–906; and S.A. NIGOSIAN, *The Zoroastrian Faith: Tradition and Modern Research* (1993). JAMES HASTINGS (ed.), *Encyclopaedia of Religion and Ethics,* 13 vol. (1908–26, reissued 1962); and MIRCEA ELIADE (ed.), *The Encyclopedia of Religion,* 16 vol. (1987), contain many articles on Zoroastrianism. GEO WIDENGREN, *Die Religionen Irans* (1965), is comprehensive. MARY BOYCE (ed. and trans.), *Textual Sources for the Study of Zoroastrianism* (1984), is a compilation of translations.

Texts covering specific aspects of Zoroastrianism are J.R. HINNELLS, "Zoroastrian Saviour Imagery and Its Influence on the New Testament," in *Numen,* 16:161–185 (December 1969); STANLEY INSLER, *The Gāthās of Zarathustra* (1975); SIMONE PÉTREMENT, "Sur le problème du gnosticisme," in *Revue de Métaphysique et de Morale,* 85:145–177 (April–June 1980); P. LECOQ, "Ahura Mazdā ou Khvarnah," in *Acta Iranica,* 23:301–326 (1984); and JAMSHEED K. CHOKSY, *Purity and Pollution in Zoroastrianism: Triumph Over Evil* (1989), examining the Zoroastrian ritual of purity throughout history. Works dealing specifically with the Parsis of India include ECKEHARD KULKE, *The Parsees in India: A Minority as Agent of Social Change* (1974; originally published in German, 1968), which studies their history in the 19th and 20th centuries; and JER D. RANDERIA, *The Parsi Mind: A Zoroastrian Asset to Culture* (1993). (J.D.-G./Ed.)
